NATIONAL SPORTING LIBRARY & MUSEUM

ACQUIRED 2019

THE GIFT OF

Hazle

Edens

The Goddess CERES *in her* Chariot *drawn by* Dragons, *Teaching* MANKIND *the* Art *of* Husbandry.

A

COMPLEAT BODY

OF

HUSBANDRY.

CONTAINING

RULES for performing, in the moſt profitable Manner,
The whole Buſineſs of the FARMER, and COUNTRY GENTLEMAN,

IN

CULTIVATING, PLANTING, and STOCKING of Land;

IN

Judging of the ſeveral Kinds of SEEDS, and of MANURES; and in the Management of ARABLE and PASTURE GROUNDS:

TOGETHER WITH

The moſt approved Methods of Practice in the ſeveral Branches of
HUSBANDRY,
From *Sowing the* SEED, to *Getting in the* CROP;

AND

In *Breeding* and *Preſerving* CATTLE, and *Curing* their DISEASES.

To which is annexed,

The whole Management of the ORCHARD, the BREWHOUSE, and the DAIRY.

Compiled from the Original Papers of the late THOMAS HALE, Eſq;

And enlarged by many New and Uſeful Communications on Practical Subjects,

From the Collections of Col. STEVENSON, Mr. RANDOLPH, Mr. HAWKINS, Mr. STOREY, Mr. OSBORNE, the Rev. Mr. TURNER, and others.

A WORK founded on Experience; and calculated for general Benefit; conſiſting chiefly of Improvements made by modern Practitioners in Farming; and containing many valuable and uſeful Diſcoveries, never before publiſhed.

ILLUSTRATED WITH

A great Number of Cuts, containing Figures of the Inſtruments of Huſbandry; of uſeful and poiſonous Plants, and various other Subjects, engraved from Original Drawings.

Publiſhed by his Majeſty's Royal Licence and Authority.

LONDON:

Printed for T. OSBORNE and J. SHIPTON in Gray's-Inn;
J. HODGES on London-Bridge; T. TRYE near Gray's-Inn Gate;
And S. CROWDER and H. WOODGATE in Pater-Noſter Row.

M.DCC.LVI.

LONDON

The PREFACE,

CONTAINING

The Plan of the WORK as publiſhed by the Proprietors with the firſt Numbers.

THE Occaſion of this Work aroſe from certain *Materials*, very conſiderable in *Quantity*, and, as we were informed, much more in *Value*; which came into our Hands by Purchaſe. They were collected by a Gentleman lately *deceaſed*, whoſe *Name* we are now authoriſed to mention; and were intended by him for the *Preſs*. They contain, as he obſerves, in an Introduction prefixed to them, what he had found of Value relating to the Subject in *Authors*, what he had learnt by Converſing with the moſt *intelligent Farmers*; and all he had diſcovered by an *active Experience* of more than *thirty* Years.

The Account we received of theſe *Papers* from ſome *undoubted Judges* into whoſe Hands we firſt put them, confirmed us in the Opinion that they might be *ſerviceable* to the *Publick*, as well as *advantageous* to *ourſelves*. The Methods we have taken to improve, illuſtrate, and compleat the Plan, the Publick have ſeen; and we hope they have appeared to them as *proper*, as they *ſeem* to us to have been *ſucceſsful*.

In Conſequence of our Advertiſements, we received many *Additions* in the different *Branches*; and were offered the Aſſiſtance of ſeveral Perſons of *Knowledge* and *Experience* in the Subject, to *methodize* and put the finiſhing Hand to every *Part*.

Being determined to ſpare no *Expence* or *Pains*, toward the rendering ſo *uſeful* an Undertaking as compleat as poſſible, we *purchaſed* every Paper of *Value brought* to us; and engaged ſo *many* of the *Hands offered* to our Aſſiſtance, that every *ſeparate Branch* fell under the Care of a *diſtinct Perſon*, who was a Maſter of that *Subject*.

It is now our Duty to thank thoſe Gentlemen from whom we have received Obſervations relating to the Subject in the *Counties* where they *live*, and whoſe *Names* with their Permiſſion we have inſerted in the Title.

The *firſt* Thing that appeared upon the Peruſal of *theſe Papers*, was the *great Inſufficiency* of all other *Books* written on this *Subject*: and the Want of *ſuch a Work* as the Materials they contained might ſupply, was not leſs evident.

The Authors who have written on *Huſbandry* have all failed, either in *Matter*, or in *Manner*. They have not been able to *inſtruct* the *Farmer*; or have not been Maſters of *Expreſſion* to convey their *Knowledge*. They have either treated *ſuperficially* what they only pretended to *underſtand*; or have buried their Experience under ſuch a Load of *needleſs* and *ill choſen Words*, that it has been found very difficult to underſtand them.

As we were aſſured there was *ſufficient Knowledge* contained in our Materials, we deſired the *Style* might be *plain* and *clear*; intelligible to the *Farmer*, and not below the *Gentleman*: ſo that every *Part* might be acceptable to every Reader.

After this Care that the preſent Work might be *underſtood* by *all* Perſons, we made Proviſion that they ſhould alſo in other Reſpects underſtand *one another*. Till this Time a Diſcourſe on the Subject of Huſbandry between the *Landlord* and his *Tenant*, was generally unintelligible to both: nor did the Farmer of *one* County underſtand the Language of him who lived in *another*. The moſt uſeful *Writings* have alſo loſt their Effect from the ſame *Cauſe*. This was an old and *general* Complaint; but no *Remedy* had been *hitherto applied*.

The Misfortune ariſes *ſolely* from the employing *Terms* in the *Art*, and *Names of Things*, uſed and underſtood only in *particular Places*, or only by the *working People*. To prevent this, not only all the Terms uſed in the preſent *Treatiſe* are clearly explained; but thoſe alſo which have been employed by *others*: So that Huſbandry will, we hope, be hereafter as generally underſtood, as it is univerſally uſeful.

Having thus explained the Manner in which our Plan has been *executed*; it will be proper to lay before the Public a ſhort View of what it contains.

We have uſed, as before obſerved, *all Endeavours* to compleat the Original Author's *Deſign*: and an Undertaking ſo extenſive, we are ſenſible leſs than the Aſſiſtance of *numerous Communications*, and the Labours of *many Perſons*, could never have *accompliſhed*.

Agriculture is here traced from its *ſmall* and *ſimple Original*; followed through the *ſeveral Ages*, and examined in the *Practice* of the *different Nations*, wherein it has been *improved* down to the *preſent* Time. From the *Harveſt* of the *old Romans*, it is purſued through the *Vineyards* of the *modern Italy*: nor are the late Improvements in *France*, or the uſeful Labours of the *Swede* or *Ruſſian* omitted. The Practice of one Country differs from that of others; yet they may learn one from another. Where the ſame Means have been uſed in different *Places*, and a different Event has followed; the Attempt has been to find the *Cauſe* of the Succeſs or Failure: that the Truth might be rendered apparent even from Contrariety.

Some Rules the Author has indeed collected from *Books*; but they appear little either in *Quantity* or *Uſe*, when compared with what he has *delivered* from *his own*, and *others Experience*. Having conſidered the *whole Compaſs of Huſbandry*, he takes it *all* for his Subject; comparing what he had *read* with what he had *ſeen*, and confirming or rejecting *Theory* by *Practice*.

The Gentlemen whoſe *Aſſiſtance* we have procured, have followed the *ſame* Plan; collecting from *Authors* whatever of Value he had omitted; and having thus inſerted in the Work a *Summary of all that has been written* on *Huſbandry*, they have added the much more *important* and much *larger Part*, all that has been diſcovered by modern *Practice*. Where Authors and Experience *diſagree*, they take *Experience* for their Guide; and where the Practice of one County, ſeems to contradict what has been advanced upon the Cuſtoms of another, the Determination is made on the Reſult of a careful *Compariſon*.

In this Work the *leaſt Things* are regarded with *Attention*, for the greateſt Events frequently *depend* on them. Nothing is aſſerted but upon *Experience* or *Proof*. The *old* Practice of Huſbandry is condemned or eſtabliſhed by the *new*. Eaſy and familiar Things are delivered firſt; and from them, gradual *Advances* are made to the more *difficult*. The Farmer will be thus led by the Hand, through his whole Buſineſs; and the *Landlord* will be *inſtructed with him*. The latter will be able to know in all *Circumſtances*, whether the other conduct himſelf *right*; and the Tenant cannot remain *ignorant* unleſs by his own *Fault*.

By theſe Means we hope the Advantages of our *Work* will be as *extenſive* as the *Plan*. The Information of the *Farmer* is the enriching of the *Landlord*: and the great Endeavour of our Undertaking is Inſtruction; as the ſole End propoſed from it is Uſe.

As the *Compaſs* of our Undertaking is ſo *large*; and the *Heads* it comprehends are ſo *very numerous*, we are ſenſible that a great deal of the *Plainneſs* and

Pre-

Propriety of the Work, muſt depend upon *their* proper *Arrangement.*

In the Intent therefore of leading the *practical Huſbandman* through the ſeveral *Branches* of his *Profeſſion*, he ſhall be introduced to the *Seat* of his *Induſtry*, (whether his own or rented) and the Work begun with *that Article* which is to come firſt under his Conſideration, the *Soil.*

This ſhall be treated of under its ſeveral natural Diſtinctions, whether it be *Clay*, *Loam*, *Sand*, *Gravel*, *Chalk*, or *Mellow Earth*, conſidering, if *Clay*, to which of the *four principal Kinds* it belongs; and in what Manner it may be *meliorated:* as alſo whether *Pits* may be opened for the *Pottery*, or *Brick* and *Tile-making*; for the *Brewery*; or *burning* for the Service of *other Lands.*

When we have in the ſame Manner, gone through the other five Kinds of Soil in Reſpect to their *Improvement* for Culture, and their *various Uſes*; we examine for what Purpoſes they are beſt ſuited, from their *Situation*, as well as *natural Qualities: Which* will be fitteſt for *Arable*, which for *Paſture:* whether in any Part *Marle* may be found at a *Depth*; or *Peat* near the Surface: in what Places *Art* may turn to Advantage the Imperfections of *Nature:* How the *Fenn* may furniſh a *Decoy*; and *Pits* may be converted into *Fiſh Ponds.*

From the Conſideration of the *Soil*, we ſhall riſe to that of the *Manures*; the numerous Kinds of which will be deſcribed; their Properties explained; and the particular Species pointed out, for different Services.

From theſe we ſhall enter on the Nature of the *Fences* in our ſeveral Counties; and treat at large of *Ditching*, *Draining*, *Hedging*, and *Planting*; of the Profits ariſing from *Coppice Wood*; and of the *Timber Trees* fit for ſeveral *Soils*, *Expoſures* and *Situations:* of the *Oak*, *Aſh*, *Elm*, *Beech*, *Maple*, *Walnut*, *Pear Tree*, &c. Under the Article *Oak* will be delivered the ſeveral Methods of *ſowing* the *Acorn*, and raiſing the *Tree* to its full *Strength* and *Value*; Rules for judging of the *Timber*, and the Ways of *ſeaſoning* it for laſting: giving the *Preference* under each Head, according to *Experience.* In the ſame Manner the reſt alſo will be conſidered.

After *planting* will be delivered the beſt Methods of *ſtocking* the Farm, under the Heads of the *Field*, *Yard* and *Stable.* And here will be introduced the Management and Advantages of the *Cow*, *Sheep*, *Horſe*, *Hog* and *Poultry.* On each of theſe Heads a *great Number of Rules* will be laid *down*, founded on ſucceſsful *Practice*; and reſpecting their *Breed*, their *Value* at their ſeveral *Ages*, their *Feeding*, and entire *Management.*

When the Farm is thus *prepared*, *planted* and *ſtock'd*, we ſhall advance to what more immediately bears the Name of *Huſbandry.* This will be conſidered as *general*, or *particular.* The ſeveral Kinds, reſpecting particular Articles, and diſtinguiſhed by the Names of *Drill Huſbandry*, and *Horſe-hoeing Huſbandry*, will be *explain'd*; and their *Advantages* and *Defects* ſhewn from the Reſult of *frequent Trials.*

The Practice of the Farmers in *different Counties* will be then *laid* down; and from the whole the careful Huſbandman will be fully informed with regard to *Plowing*, *Sowing*, *Harrowing*, *Rolling*, *Hoeing*, *Pulling*, *Cutting* and *Carrying.*

From theſe *general* Inſtructions, he will be led to the Conſideration of the ſeveral *Kinds* of *Seeds*: Under which Head he will be made acquainted with the *Nature*, *Properties*, and *Preparations* of *Wheat*, *Barley*, *Rye*, *Oats*, *Beans*, *Peas*, *Tares* and *Lentils.*

From theſe he will be led to the Knowledge and *Culture* of the ſeveral Kinds of *Graſs*; to be ſown either ſingly, or with his Corn. Here he will be inſtructed in the Nature, Value and Qualities of *Common Graſs*, *Clover*, *Saint Foyne*, *Lucerne*, and the like.

After which will be ſhewn at large the Culture and Uſes of ſuch *Roots* as may be advantageouſly planted in *Fields*; as the *Turnep*, *Potatoe* and *Carrot.*

From *theſe*, the Subject will naturally bring him to ſuch Articles as, tho' leſs *univerſal*, are not leſs *advantageous.* Among theſe will be particularly delivered the *Culture*, *Management* and *Profits* of *Hops*, *Flax*, *Hemp*, *Woad*, *Weld*, *Coleſeed*, *Liquorice* and *Saffron*, with Inſtructions concerning *Madder*, and ſome others, which tho' not cultivated at this Time in *England*, might be introduced with great Advantage.

From the immediate *Subjects* of his *Profeſſion*, he will be brought to the Conſideration of their *natural* and *artificial Products*; and among theſe particular Regard will be had to the *Uſe* and *Management* of *Milk*, *Cream*, *Butter*, *Cheeſe*, *Wool* and *Leather.*

The Accidents to which his *Cattle* or his *Crops* are liable, will after this be laid *down*; and the *Diſeaſes* to which they are *ſubject*; with the moſt *approved* Methods of *preventing* or *remedying* each.

Under the firſt Head will be ſhewn the Effects of *Drought*, *Rains*, *Hail*, *Snows*, *Winds* and *Blights*; at what *Times* they are to be *expected*; and by what *Means* the ſeveral Objects of Huſbandry may be moſt effectually *ſecured* againſt, or beſt *preſerved* from them.

The other Head of Enquiry will lead to the *Diſeaſes* and *Diſtemperatures* of his *Cattle*, *Corn* and *Trees.* Under the firſt Article will be conſidered the *Murrain*, the *Rot*, the *particular Diſtemper* now raging among the *horned Cattle*, and their being poiſoned by unwholeſome *Herbs*, *Inſects*, or *Waters.*

The *Cauſes* as well as *Symptoms* of theſe ſeveral Diſorders will be explained from *repeated Obſervations*, and the *Concurrence* of *Authors* and *Experience:* and the beſt *known* Remedies for *each* will be *ſet down.*

The Diſtemperatures of *Vegetables* will be arrang'd under three Heads, as they affect *Trees*, or *Roots*, *Corn*, and other *Herbage.* And in the Enquiry into their *Cauſe* and *Origin*, will be conſidered at *large* the Miſchiefs occaſioned by *Inſects*, as the *Fly*, *Slug*, *Worm*, *Grub*, *Caterpillar* and *Locuſt*; and every Method will be *inſerted* which *Experience* warrants, or *Reaſon* recommends to the Trial, for *their Deſtruction*, or the *Preſervation* of the *Crop.*

To theſe will be ſubjoin'd the Miſchiefs to which *Corn* and other *valuable Growths* are ſubject from *Weeds* and *Birds*, and the *eaſieſt* and moſt *certain* Methods will be delivered for the *Extirpation* of the one, and for Preſervation from the other.

From the ample, diſtinct, and plain Manner in which *theſe* and a Number of *other* ſubordinate Articles will be treated in the Courſe of this *uſeful* Work, we perſuade ourſelves the Farmer will be fully inſtructed how he is to conduct himſelf in the *Field*, the *Houſe*, the *Dairy*, the *Stable*, and in *Haymaking* and *Harveſt-Work*; and *that* in ſuch a Manner as to procure all poſſible *good*; and prevent all *ill* that can be *avoided*, in the Care of his *Plantations*, his *Stock* and his *Crop:* that the *Eſtabliſhed Huſbandman* will find many *profitable* things therein with which he was not *before acquainted*, and that the *young Farmer* will ſet out in his Profeſſion with the Advantage of others *Experience.*

The Plates will contain Figures beautifully engraved from Original Drawings.

1. Of the Inſtruments of Huſbandry uſed in different Counties in *England.*
2. Of all the poiſonous Plants in *England.*
3. Of the moſt uſeful and valuable Herbs wild or cultivated; and various other Subjects.

PROPRIETORS.

CONTENTS.

BOOK I.

Of the SOIL.

THE INTRODUCTION. *Treating of the Soil in general* —— —— Page 3

CHAP.

1. *Of discovering the Nature of a Soil by the Situation and Surface* —— 4
2. *Of judging of a Soil by its common Produce* —— —— ibid.
3. *Of judging of a Soil by the Growth of Trees* 5
4. *Of the several Kinds of Soils* —— 6
5. *Of clayey Soils in general* —— — 7
6. *Of red clayey Soils for Tillage* — ib.
7. *Of red clayey Soils for Pasturage* 9
8. *Of red clayey Soils for Trees* —— 10
9. *Of yellow clayey Soils for Tillage* —— 11
10. *Of yellow clayey Soil for Pasturage* 13
11. *Of yellow clayey Soils for Trees* —— 14
12. *Of the white clayey Soil* —— ib.
13. *Of the black clayey Soil* —— ib.
14. *Of loamy Soils* —— —— 16
15. *Of sandy Soils* —— —— 18
16. *Of gravelly and stony Soils* —— 20
17. *Of chalky Soils* —— —— 22
18. *Of mellow Earth* —— —— 24

Appendix to the FIRST BOOK.

Of the Uses of Clay, Loam, Sand, and other Substances found on or in the Earth, in the various Arts; and their Value to the Owner.

The INTRODUCTION. *Of the Design and Bounds of this Appendix* —— —— 28

CHAP.

1. *Of the Uses of Clay* —— —— ib.
2. *Of the Uses of Loam* —— 31
3. *Of the Uses of Sand* —— —— 33
4. *Of the Uses of Gravel* —— 34
5. *Of the Uses of Chalk* — —— 35
6. *Of Fullers Earth* —— —— 36
7. *Of Ochre* —— —— 37
8. *Of Peat* —— —— 38

BOOK II.

Of MANURES. In TWO PARTS.

I. *Of* NATURAL MANURES.

The INTRODUCTION. *Of Manures in general* 41

CHAP.

1. *Of the Nature of Marle* —— 42
2. *Of the several Kinds of pure, or unmixed Marles* —— —— 43
3. *Of the several Kinds of impure or mixed Marles.* —— — 44
4. *Of certain Marles found in particular Counties* —— —— ib.
5. *Of seeking Marle* —— —— 46
6. *Of suiting Marle to the Land* —— 47
7. *Of the Manner of using of Marle* — 49
8. *Of the vast Fertility of marled Lands* 51
9. *Of the Use of Mud as a Manure* 52
10. —— *Clay as a Manure* — 53
11. —— *Loam as a Manure* 55
12. —— *Sand as a Manure* 56
13. —— *Gravel as a Manure* 58
14. —— *Stone as a Manure* 59
15. —— *Chalk as a Manure* 60
16. —— *Salt as a Manure* 62
17. —— *Sea Weeds as a Manure* 63
18. —— *Sea Shells, and their Spawn, as Manure* —— —— 64
19. *Of Parts of Trees and Plants, us'd as Manure* 65

CHAP. Page
20. *Of Parts of Animals, uſed as Manure* 66
21. *Of Dung in general as Manure* ib.
22. *Of Horſe-Dung* — 68
23. ——— *uſed ſingly or alone* 70
24. ——— *made into Compoſt* ib.
25. *Of laying on of Dung* — — 71
26. *Of the Virtue and Quantity of Horſe-Dung* ib.
27. *Of Cow Dung* — — 72
28. *Of Sheeps Dung* — — ib.
29. *Of Hogs Dung* — — 74
30. *Of Pigeons Dung* — — 75
31. *Of the Dung of Poultry* — ib.
32. *Of human Excrement* — — 77
33. *Of Urine* — — 78
34. *Of Rags* — — 79

II. *Of* ARTIFICIAL MANURES.

35. *Of Lime; its Materials, and Manner of burning it* — — 80
36. *Of the Manner of uſing Lime as a Manure* 81
37. *Of Soot* — — 87
38. *Of Aſhes* — — 88
39. *Of Burnbaiting* — — 90
40. *Of the ſeveral Kinds of Baſtard Burnbaiting* — — 93

BOOK III.

Of the Improvements of Land by Incloſing and Draining; and of the ſeveral Kinds of Fences.

The INTRODUCTION. *Of Incloſure in general* 97

CHAP.
1. *Of the great Advantages of Incloſure* 98
2. *Of the more particular Benefits of Incloſure, and the Objections againſt it* — 99
3. *Of the ſeveral Kinds of Fences* — 102
4. *Of Ditches, and their Uſe in Fencing* 103
5. *Of Draining in general* — 105
6. *Of draining boggy Lands* — ib.
7. ——— *fenny Lands* — 107
8. ——— *flat Lands near great Rivers* 109
9. *Of the ordering of Salt Marſhes* 110
10. *Of Hedges* — — 113
11. *Of raiſing the Quickſet, for a White Thorn Hedge* — — ib.
12. *Of making the Hedge* — 114
13. *Of the Seaſons for Planting, and the Choice of White Thorn* — — 115
14. *Of keeping the Hedge in Order* — 116
15. *Of Plaſhing of a Hedge* — 117
16. *Of the Profit that may ariſe from Hedges* 119
17. *Of the Sloe, or Black Thorn Hedge* 120
18. *Of the Furze Hedge* — ib.
19. *Of the Holly Hedge* — 122
20. *Of the Elder Hedge* — 123
21. *Of the Uſe of the Crab, Sallow, Alder, and Bramble in Fencing* — 125
22. *Of the Bank Fence, with its Plantation* ib.
23. *Of the Wall Fence, with its Plantation* 127

BOOK IV.

Of Coppice Wood, and Timber Trees. In THREE PARTS.

I. *Of* COPPICE *and other* SMALL WOOD.

The INTRODUCTION. *Of the Improvements made by Planting* — — 131

CHAP.
1. *Of raiſing a Coppice from Seed* 133
2. *Of raiſing a Coppice by planting of Sets* 135
3. *Of the managing and ordering a Coppice in its Growth* — — 136
4. *Of felling of Coppices* — 138
5. *Of Pollards, or Trees for Shrowding* 139

II. *Of the Management of* TIMBER TREES.

6. *Of Timber Trees in general* — 141
7. *Of raiſing Tember Trees from Seed* 143
8. *Of propagating Timber Trees by Tranſplantation* — — 144
9. *Of tranſplanting Trees of a large Growth, and at improper Seaſons* — 145

III. *Of the ſeveral Kinds of* TIMBER TREES.

10. *Of the Oak* — — ib.
11. *Of raiſing the Oak by Tranſplantation* 146
12. *Of raiſing the Oak from the Acorn* 147
13. *Of the Uſes of the Oak* — ib.
14. *Of the Growth of the Oak* — 149
15. *Of the felling of the Oak* — 150
16. *Of the ſeaſoning Oak, and judging of the Timber* — — ib.
17. *Of judging of the Oak as it ſtands* 151
18. *Of the Elm, its Kind, and proper Soil and Situation* — — 152
19. *Of the Propagation of the Elm as Timber* 156
20. *Of the Uſes of the Elm in Plantations* 155
21. *Of the Value of Elm in Timber* 156
22. *Of the Aſh, its proper Soil and Situation* 157
23. *Of the Propagation of the Aſh* 158
24. *Of raiſing Aſh in a Nurſery* — ib.
25. *Of raiſing Aſh, where it is to ſtand* 159
26. *Of lopping and felling the Aſh* 161
27. *Of the Uſes of the Aſh, its Value in Plantations, and as Timber* — ib.
28. *Of the Beech, its Soil and Situation* 162
29. *Of the Propagation of the Beech* 163
30. *Of the Uſes and Value of the Beech* 165
31. *Of the white Poplar, its Soil and Situation* 166
32. *Of the Propagation, and Uſes of the white Poplar* — — 167
33. *Of the black Poplar* — 168
34. *Of the Aſpen Tree* — — ib.
35. *Of the Sycamore* — 169
36. *Of the Lime Tree* — — 170
37. *Of the Walnut Tree* — 172
38. *Of the Horſe Cheſnut Trees* — 174
39. *Of the Cheſnut Tree* — 175
40. *Of the Service Tree* — 176
41. *Of the Quickbeam* — — 177
42. *Of the Birch* — — ib.
43. *Of the Horn Beam* — 178
44. *Of the Maple* — — 179
45. *Of the Cherry Tree* — 180

Chap.		Page
46.	*Of the Pear Tree*	182
47.	*Of the Hazel*	ib.
48.	*Of the Buck Thorn*	183
49.	*Of the Alder*	184
50.	*Of the Willow*	185
51.	*Of the Ozier*	186
52.	*Of the Sallow*	187
53.	*Of the Fir Tree*	188
54.	*Of the Pine Tree*	190
55.	*Of the Juniper*	191
56.	*Of the Yew*	ib.
57.	*Of the Box*	192
58.	*Of the Cypress Tree*	193
59.	*Of the Cedar*	194

BOOK V.

Of the Animals necessary and useful in Husbandry and Farming.

In FOUR PARTS.

I. *Of* Cattle:

The Introduction. *Of Stocking the Farm* 197

Chap.		
1.	*Of the Horse in general*	ib.
2.	*Of the Choice and Management of Horses for the Farm*	198
3.	*Of the Saddle Horse for the Husbandman*	200
4.	*Of the breeding of Horses*	ib.
5.	*Of weaning Foals*	202
6.	*Of breaking Horses for Service*	203
7.	*Of the Farmer's Number of Horses, and their working*	204
8.	*Of the turning Horses to Grass, and taking them up to the Stable*	205
9.	*Of the Ass*	206
10.	*Of the Mule*	208
11.	*Of the Bull, and his Kind*	209
12.	*Of the Ox*	211
13.	*Of the Cow*	215
14.	*Of the Calf*	217
15.	*Of Sheep, and their several Breeds in this Country*	219
16.	*Of the Choice of Sheep*	220
17.	*Of the breeding of Sheep*	221
18.	*Of the shearing of Sheep*	223
19.	*Of the breeding up of House Lambs*	224
20.	*Of Hogs, their Advantages and Evils*	225
21.	*Of the several Breeds or Kinds of Hogs*	226
22.	*Of the feeding of Hogs*	227
23.	*Of Goats*	229
24.	*Of the Rabbit in general*	230
25.	*Of the wild Rabbit*	ib.
26.	*Of the tame Rabbit*	231
27.	*A profitable Method of keeping tame Rabbits*	232

II. *Of* Fowls.

Chap.		
28.	*Of the Cock and Hen, their Kinds and Choice*	233
29.	*Of the breeding of Poultry*	235
30.	*Of the bringing up of Chickens*	236
31.	*Of Capons*	237
32.	*Of Turkeys, their Kinds and Choice*	238
33.	*Of the breeding and raising of Turkeys*	239
34.	*Of Geese, their Kinds, and the Profits of keeping them.*	240
35.	*Of the breeding and feeding of Geese*	241
36.	*Of Ducks*	242
37.	*Of the keeping of wild Water Fowl, and of Decoys*	243
38.	*Of the Swan*	244
39.	*Of the Peacock*	245
40.	*Of the Pheasant*	246
41.	*Of the Pigeon*	ib.

III. *Of* Fish.

42.	*Of the Advantages of Fish Ponds*	248
43.	*Of the making of Fish Ponds*	250
44.	*Of the stocking of Fish Ponds*	252
45.	*Of feeding, preserving, and taking Fish out of Ponds*	254

IV. *Of* Insects.

46.	*Of Bees, their Nature and Products*	255
47.	*Of Hives, and the Manner of placing them*	256
48.	*Of the swarming of Bees*	258
49.	*Of the hiving of Bees*	ib.
50.	*Of the preserving of Bees*	259
51.	*Of taking the Honey and Wax*	260

BOOK VI.

Of TILLAGE. In SIX PARTS.

I. *Of Plants, and their Nourishment.*

The Introduction. *Of Improvements in Husbandry, and the Manner to undertake them* 236

Chap.		
1.	*Of the Roots of Plants; their Kinds and Forms*	265
2.	*Of the Extent of the Roots of Trees*	266
3.	*Of the Manner wherein the Roots of Plants imbibe their Nourishment*	ib.
4, 5.	*Of the Importance and Use of the Leaves of Plants; and of Accidents arising from the Loss of them*	267
6.	*Of the Nourishment of Plants*	269
7.	*Of the Reasons there are for supposing the Nourishment of all Plants the same*	271
8.	*Other Objections to the Nourishment of all Plants, being the same, answered*	271
9.	*Reasons for it deduced from the Practice of Husbandry*	273
10.	*The Result of Experiments in Vegetation*	ib.
11.	*Of changing of Crops*	275
12.	*Of the Distribution of the Nourishment of Plants in the Earth*	276

II. *Of the Advantages of Tillage.*

13.	*Of the several Methods of dividing the Particles of Earth*	277
14.	*Of the Degrees of Tillage, and of the Use of Dung*	279
15.	*Of*	

CONTENTS.

CHAP. Page

15. *Of the joint Advantages of Manure and Tillage* 280
16. *Of the Preparation of Wood Land for Corn* 281
17. *——— of heathy Land for Corn* 282
18. *——— of Land for Corn after the artificial Graſſes* ib.
19. *——— of Land for Corn after common Graſs* 284
20. *Of keeping Land in Heart by Tillage* 285
21. *Of the Nature of the Improvement by Tillage* 286

III. *Of the Inſtruments of Huſbandry, and their ſeveral Uſes.*

22. *Of plowing* 288
23. *Of the Form of the antient Plow* 289
24. *Of the ſeveral Kinds of Plows in common Uſe in* ENGLAND ib.
25. *Of the Uſes of common Plows, and their proper Make* 291
26. *Of the Improvements on the common Plow* ib.
27. *Of the Wheel-Plow* 292
28. *Of the four coultered Plow* 293
29. *Of the Management of a Plow in working* 296
30. *Of the Advantage of Plowing croſswiſe on hilly Grounds* 298
31. *Of laying Lands in Ridges* ib.
32. *Of wet Land on Hills* 300
33. *Of wet Land that lies level* 301
34. *Of the Advantages of Tillage by the four coultered Plow* 302
35. *Of the general Benefits and Advantages of Plowing* 304
36. *Of the Benefit of converting Paſture into Arable Land, and of continued plowing* 305
37. *Of Harrowing* 306
38. *Of the various Kinds of Harrows* ib.
39. *Of the Drill Harrow* 308
40. *Of Rolling* 310
41. *Of the ſeveral Kinds of Rollers* 311
42. *Of the great Advantages of Rolling* ib.

IV. *Of the different Manners of Sowing.*

43. *Of Sowing in general* 313
44. *Of the Depth at which Seeds are to be ſown* 314
45. *The practical Method of finding the proper Depth for Seeds* ib.
46. *Of the Quantity of Seed to be ſown in the common and drill Huſbandry* 316
47. *The Practice in Reſpect of Quantity in different Places* 317
48. *Of the Advantages the Drill Huſbandry receives from the Hoe Plow* 318
49. *Of changing the Seed* 319
50. *Of the ſuppoſed Change of Species, and of* PATNEY *Barley* 321
51. *Of the Effect of Soils on the Growth of Plants* 322

V. *Of Drill and Horſeboeing Huſbandry.*

52. *Of the Nature of Drill and Horſeboeing Huſbandry in general* 323
53. *Of Drilling* 324
54. *Of Horſeboeing* ib.
55. *Of the Benefits of deep Hoeing* 325
56. *Of the different Appearance of Crops* 326
57. *Of Drill Boxes* 328
58. *Of the Wheat Drill and Turnip Drill* 329
59. *Of the Hoe Plow* 331

VI. *Of the Benefits of Drill and Horſeboeing Huſbandry ſhewn in three Sorts of Crops.*

60. *Of raiſing Turnips by the Drill and Horſeboeing Huſbandry* ib.

CHAP. Page

61. *Of the Diſpoſition of a Turnip Crop* 333
62. *Directions for Horſeboeing of Turnips* 334
63. *Of the Quantity of Seed, and Advantages of the Crop* 335
64. *Of raiſing Wheat by the Drill and Horſeboeing Huſbandry* 336
65. *Of the Number of Rows for Wheat* 338
66. *Of the Manner of Horſeboeing of Wheat* 339
67. *Of the immediate Benefit of the broad Intervals* 340
68. *Of raiſing Saintfoin by the Drill and Horſeboeing Huſbandry* ib.
69. *Of the Manner of planting Saintfoin* 341
70. *Of the great Advantages of the Drill and Horſeboeing Huſbandry* 342

Thoughts of a practical Correſpondent, on the Advantages of the new Huſbandry, &c. 343
Of making good Roads 350
The Alteration Time makes in the Value of moſt Lands ib.
Of the new Huſbandry 352
Of Wheat in general 355
Of the Quantity and Produce of Wheat 356
How Corn grows 358
How the Ground is to be prepared for Wheat 360
Of brining or ſteeping Seed Wheat 364
Colonel PLUMMER *of* HERTFORDSHIRE, *Way of ſteeping Wheat* ib.
Of ſowing Wheat ib.
How the Wheat and the Ground are to be ordered, whilſt they are together ib.
Of weeding of Corn 365
How the Wheat is to be managed when ſeparated from the Ground 366
Of the Methods of keeping of Corn 367
A Calculation of what Seed Wheat is required when ſowed at different Diſtances; and of what Produce may be reaſonably expected from each different reſpective Method 368
Of brining Corn or other Seeds 370
The Copperas Receipt 374
The ſteeping uſed by ſeveral MIDDLESEX *Farmers* ib.
Another Receipt ib.
Of BARLEY 376
How the Ground is to be prepared for Barley; and of ſowing it 379
Of Steeping ib.
Of weeding and reaping of Barley 380
Of the Produce and Advantages of Barley ib.
Of RYE 382
Of the OAT 383
Of the Uſes of Oats 384
Of the Soils proper for Oats ib.
Of Seed Oats, and the changing them 385
Of Reaping ib.
Of the Produce, and other Advantages of Oats ib.
The Advantages of Oats 386
A Calculation of the Profits of Oats 387
Of keeping of Oats 389
Of the BEAN ib.
Of the Seed, ſowing, and ſteeping 391
Of the Soil; and preparing the Ground for Beans 392
Of the Produce and Advantages of Beans 393
Of reaping Beans 394
A Machine to wheel Sacks of Corn in Granaries, Corn Chambers, &c. ib.

ADDITIONAL ARTICLES.

CHAP.

1. *Of* PEASE 395
2. *Of the Varieties of the Garden Pea, called the ſeveral Kinds of Garden Peaſe* 396
3. *Of the Culture of the Garden Peaſe* ib.
4. *Of Field Peaſe* 397
5. *Of the proper Soils for the three Kinds of Field Peaſe* ib.

6. *Of*

CONTENTS.

CHAP. — Page

6. *Of the ſowing of Peaſe.* — 398
7. *Of weeding the Pea Field.* — 399
8. *Of reaping of Peaſe.* — 401
9. *Of Tares.* — 402
10. *Of the proper Soils for Tares, and the Management of the Ground.* — ib.
11. —— *ſowing Tares.* — 403
12. —— *mowing and reaping them.* — ib.
13. *Of preſerving of ditto.* — 404
14. *The Thetch, Fetch, or Vetch.* — ib.
15. *Of the Nature of the Chich, and its Kinds.* — 405
16. —— *proper Soil for Chiches; and its Preparation.* — ib.
17. *Of ſowing Chiches.* — 406
18. *Of the Management of Chiches, and their ſtanding for Seed.* — 407
19. —— *Manner of feeding with Chiches.* — 408
20. *Of Lentils.* — 409
21. *Of the proper Soil for Lentils, and the Manner of ſowing them.* — ib.
22. —— *Management and Uſe of Lentils.* — 410
23. *Of Buck-wheat.* — ib.
24. *Of the Soil for Buck-wheat, and the Manner of ſowing it.* — 411
25. —— *Management and Uſe of Buck-wheat.* — ib.

BOOK VII.

Of natural and artificial Graſſes. In TWO PARTS.

PART I.

CHAP.

1. *Of the Diviſion of natural Graſſes into Meadow and Paſture.* — 414
2. *Of Graſs Grounds that lie high.* — 415
3. *Of Graſs Grounds that lie low.* — 416
4. *Of the Accidents to which Graſs Grounds are liable.* — 417
5. *Of Ant-hills and Mole-hills* — ib.
6. *Of clearing a Paſture Ground from Stumps and Buſhes.* — 419
7. *Of improving moſſy Paſture Ground by burning.* — 420
8. *Of improving common Graſs Ground by Manures.* — 422
9. *Of the general Management of Graſs Ground.* — 423
10. *Of Mowing.* — 424
11. *Of Hay-making.* — 426
12. *Of the Aftermath and Winter Uſe of Graſs Grounds.* — 427

PART II.

CHAP.

13. *Of artificial Graſſes in general.* — 428
14. *Of Clover, its moſt proper Soils, and the Manner of ſowing.* — 429
15. *Of the feeding Cattle on freſh Clover.* — 431
16. *Of the mowing of Clover, and its Hay.* — 434
17. *Of the Soil for Saintfoin, and its Growth.* — 435
18. *Of ſowing Saintfoin, and managing it while on the Ground.* — 436
19. *Of mowing of Saintfoin, and the Uſes of its Hay.* — 437
20. *Of Lucerne, and the Manner of ſowing it.* — 438
21. *Of the moſt proper Soils for Lucerne.* — 440
22. —— *ſowing of Lucerne, and managing it in the Ground.* — ib.
23. *Of the Value of Lucerne, and Manner of uſing it.* — 442
24. *Of Hop Trefoil.* — 443
25. *Of Ray Graſs.* — 444
26. *Of Spurrey.* — 446

BOOK VIII.

Of ſuch Roots as may be advantageouſly planted in Fields.

CHAP.

1. *Of the Soil for Turneps in the common Huſbandry, and Manner of ſowing them.* — 450
2. *Of managing Turneps in the Ground.* — 451
3. *Of the Uſes of the Turnep.* — ib.
4. *Of particular Ways of raiſing a Crop of Turneps.* — 452
5. *Of the Potatoe.* — 453
6. *Of the Soil for Potatoes, and the Manner of planting them.* — ib.
7. *Of preſerving Potatoes.* — 454
8. *Of Carrots.* — 456
9. *Of the Soil for Carrots, and its Preparation.* — ib.
10. *Of ſowing of Carrots.* — 457
11. *Of managing a Crop of Carrots, and their Uſe.* — 458

BOOK IX.

Of ſeveral advantageous Articles in Huſbandry, which are leſs univerſal than the others.

CHAP.

1. *Of Hops.* — 460
2. *Of the ſeveral Kinds of Hops.* — 461
3. *Of the proper Land for a Hop-Ground.* — 462
4. *Of placing the Hills.* — ibid.
5. *Of planting the Hops.* — 463
6. *Of dreſſing and managing a Hop-Ground.* — 465
7. *Of polling the Hops.* — ib.
8. *Of inſpecting the polling.* — 467
9. *Of the tying of Hops.* — ib.
10. *Of clearing the Ground and raiſing the Hills.* — 468
11. *Of ſhortening the Hop-Plant.* — ib.
12. *Of the gathering of Hops.* — 469
13. *Of the drying of Hops.* — 471
14. *The* FLEMISH *Manner of drying Hops.* — 471
15. *The Way of drying Hops in a Malt Kiln.* — 472
16. *Of drying Hops in a Malt Kiln fitted to the Purpoſe.* — ib.
17. *Of the bagging of Hops.* — 473
18. *Of the Management of the Hop-Ground after the Hops are gathered.* — 474
19. *Of dreſſing an old Hop-Ground.* — 475
20. *Of reſtoring a decayed Hop-Ground.* — 476
21. *Of watering a Hop-Ground.* — ib.

LETTERS from Correſpondents on different Subjects.

LETTER 1. *On the Choice of Ground, and Manner of Planting.* — 417

Chap.		Page
	Letter 2. *On the Planting and Management of Hops the first Year*	478
	3. *On the picking of Hops*	ib.
22.	*Of Flax*	479

The Perſon to whom the Proprietors of this Work have committed the Care of its Publication, having received Accounts, from many Parts of the Kingdom, of the great Damage done by the late Floods in overflowing large Quantities of Land, applied to that ingenious Gentleman who favoured them with the moſt judicious and uſeful Method of Stacking Hay to prevent its firing, publiſhed in a former Number, to requeſt his Advice to the Farmers in this great Calamity: he has in Return been favoured with the following Letter, committed to the Care of Mr. OSBORNE, *one of the Proprietors; which, with the utmoſt Gratitude for the Obligation, he here preſents to the Reader.*

Mr. OSBORNE,

Jan. 15, 1756.

SIR,

I Have peruſed Mr. ------'s Letter to you of this Date. That learned and uſeful Member of Society, as well as great Genius, does me much Honour in declaring, my ſimple Contrivance for Stacking Hay with Safety, met with the favourable Reception and good Opinion of the Publick; and that it has been of any Service and Credit to ſo important, and, as far as I am able hitherto to judge, ſo excellent a Work as the preſent *Body of Huſbandry*; every Number of which I wait with Impatience, and read with Satisfaction; pleaſing myſelf with a conſcious View of Ten Thouſand *Cornu Copia's*, and national Benefits riſing out of it.

If the Remainder of this noble Work be equally conſidered, and equally ſupported by Science and Practice, I ſhall not heſitate to pronounce it an Honour to the BRITISH Nation, as well as the Undertakers; and doubt not but it will ſoon fly through the living Languages of EUROPE.

I flatter myſelf the Plan and Deſcription of my new invented Granary, which I deſired you to tranſmit to the Gentlemen concerned, may merit their Conſideration: it coſt me much Thought and Contrivance to make it ſtrictly ſupportable by the Laws of Pneumaticks, and to anſwer all its Purpoſes with Oeconomy, and without the late ingenious Invention of Ventilators, to which the ENGLISH and FRENCH have hitherto confined themſelves.

That learned Gentleman makes uſe of an Argument that will always command my Regard and beſt Endeavours, the *Publick Good*; and he has with Sincerity, my warmeſt Deſires to ſerve them, and oblige him in his Requeſt.

I ſhall firſt ſay, in the preſent Caſe, that I apprehend no Engine in Nature can be properly and efficaciouſly applied, to the ſpeedy draining of great Surfaces of Lands accidentally overflowed.

We muſt allow that Wind, Sun, falling of Rivers, and Imbibition of the Earth are the Productions of the great Engineer: He leaves it to us to find or create Levels, in this particular Caſe, if we are impatient of his Operations; and He expects we ſhould, on ſuch Occa-

Occaſions, add the Knowledge and Skill with which he has bleſſed us.

I ſhall only obſerve, nothing can be attempted by us, whilſt one uniform Surface of Water covers contiguous Rivers, Drains, Ditches, and Lands, as in many Places it does at preſent; but the Moment ſuch Rivers or Drains have acquired a natural Level, by the running off of ſome Part of the Inundation, the higheſt Parts of thoſe overflowed Lands beginning to appear, the moſt adviſeable Inſtrument to apply is the LINCOLNSHIRE trenching Plow, or, for want of it, a ſtrong common two wheel Plow; beginning near the River, or Level's Edge, and cutting up as far as conveniently may be, into the ſhallow Verge of the ſtagnant Inundation: aſſiſting the Cut occaſionally with the Spade.

This main Cut, after the Waters have wholly diſappeared, ſhould be enlarged in Depth and Breadth, and ſeveral ſmaller lateral Cuts be made with the Plow, where the gradual falling of the Body of Water indicates; by marking out daily the ſucceſſive Verges of all the ebbing Pools or Shallows, that approach neareſt to the Level of the main Cut, and afterwards running the Plow along ſuch marked Lines of Direction, thereby opening the eaſieſt Communications between the ſeveral Shallows and the main Cut; employing the Spade alſo in ſuch lateral Cuts where neceſſary.

This is the beſt Time to diſcover the trueſt and moſt advantageous Situation for ſuch open Drains, and to obviate an injurious Duration of ſuch future Floods or Inundations, Water being the beſt and cheapeſt Level for the induſtrious Farmer when it happens ſo; and its Retreat, eſpecially in large Paſtures, ſhould be carefully watched and ſtaked out with ſmall wooden Pins.

The young Farmer need only be told farther, that all ſudden Floods, of ſhort Duration, are greatly beneficial to Graſs Lands, as they convey and depoſit Matter of great Fertility upon the Grounds they ſo viſit. But theſe differ widely from the preſent grievous continued Inundations. I heartily wiſh theſe Hints may prove uſeful, and am, with Compliments to ----- for the Honour he does me,

SIR,

Your obliged humble Servant,

JOHN STEVENSON.

TO THE READER.

THE *Deſign of this Work is to inform the induſtrious Huſbandman in what manner he may get moſt by his Farm; at the ſame Time doing leaſt Damage to the Land; or in many Caſes improving it at the while.*

What we ſhall ſay on theſe Heads will be uſeful to the Land-owner as well as to the Tenant: and we ſhall be glad to inſtruct the Gentleman, while we aſſiſt the Farmer.

Many Things have been written concerning Huſbandry; ſome true and others falſe: but all that is valuable in thoſe Books may be comprized in a ſmall Compaſs; and we ſhall make it one part of our Buſineſs to pick the few Grains of Corn from the Loads of Chaff, and preſent them clean to the Reader.

A great deal has been done of late Years to amend the old Methods of Huſbandry; but the Experiments have been made ſome in one Place, and ſome in another. In treating of theſe we ſhall take the needful Pains to collect all together; and after that leave the experienced Farmer to make his Choice of ſuch as beſt ſuit his Purpoſe; tho' not without Advice on each Head.

Many Things have been of late alſo publiſhed as Diſcoveries of great Advantage, which have their Grounds only in Fancy or Miſtake: theſe we ſhall carefully ſeparate from the true Improvements; condemning them as they deſerve: for, to miſlead the practical Huſbandman by falſe Relations; and entice him to a new Method by great Promiſes, which have not their Foundation in Fact, is both wicked and cruel.

This has been the Fault of many Books on the Subject; and too often an induſtrious Family has been ruined by believing them. It is this Cuſtom of boldly advancing Falſities, that has brought Diſcredit upon the Truth; and to the ill Succeſs of Experiments propos'd by ſuch deceitful Perſons, is owing the preſent Backwardneſs to meddle with any new Practice.

The Generality of Writers complain heavily of this Unwillingneſs in the Country People to follow their Methods; and they give it the harſh Names of Obſtinacy and Folly: the worſt exclaim the moſt; and all of them with very little Reaſon.

It becomes us to ſay, on the contrary, upon our own Knowledge, that

either

either the Farmers of this Kingdom are at preſent very different from thoſe who lived when ſome of theſe Complaints were made; or elſe that the Accuſations were altogether falſe.

Dr. PLOT *ſays, in his Hiſtory of* Oxfordſhire, *that the Huſbandmen of that County would neither tell him what were their old Methods of proceeding, nor learn from him any others: Dr.* MORETON, *in his Account of* Northamptonſhire, *makes the ſame Complaints; and many other Inſtances might be produced.*

The Gentleman, upon whoſe Materials this Work is founded, has been in both thoſe as well as moſt of our other Counties; and it appears plainly, from his Account, that the Farmers in each were very willing to let him know their own Practice; and as ready to give any new Method a fair Tryal, which was propoſed to them in a plain and reaſonable Manner.

This Gentleman actually made many Improvements in the Huſbandry of thoſe Counties, as will be ſeen hereafter; and he every where ſpeaks of the Farmers, as we have always found them, both there and elſewhere, a plain upright ſenſible Body of Men: who for the Sake of their Families will continue in their old Courſe, except a new one that is propoſed be well explained to them: but who are always ready to hear ſuch as are able to inſtruct them.

Many Improvements will be propoſed to their Conſideration in the enſuing Sheets; but in order to ſuit the Work to Reaſon and Experience, we ſhall every where ſhew upon what Grounds they are founded; and we hope they will then take or refuſe them, according to their own Judgments.

But altho' there will be many new Things thus offered in our Work, it will not conſiſt of ſuch entirely. We ſhall in general be more careful to improve the old, than ambitious to advance new Methods. We ſhall in every Article endeavour to teach the conſiderate Farmer to make the beſt Uſe of his own Experience, and ſhall deſire he will let it in all Things finally direct and guide him.

When that which is propoſed, tho' it be ever ſo new, is in itſelf right, what he before knows in general of the Subject will confirm it: and if that ſafe and wiſe Adviſer, his Experience, in any Part fairly condemn the Practice, let him not think it worth a Tryal.

We propoſe, upon the whole, to lay before the young Huſbandman a uſeful Plan, and teach him to follow it with Spirit, and Diſcretion: to tell him how to purſue an Advantage, and where to ſtop: and, in this Manner, if any one be ignorant, to inſtruct him; and if any one be poor, who is willing to be induſtrious, to ſhew him the Way at once to enrich himſelf, and to oblige and ſerve his Landlord.

With an Explanation of their ſeveral Natures, and general Directions for their Improvement.

The INTODUCTION.

Treating of the Soil in general.

THE Soil is the Ground or Earth, in which the Farmer's Crop is to grow.

A pure Soil is a fine mellow Mould, without any Mixture of other Matter; but this is found only in a few Places. All other Soils are compoſed of this Mould, with natural Additions of one or more leſs fertile Ingredients; ſuch as Sands, Stones, Clay, and the like: and according as theſe are in a greater or leſſer Quantity, the Soil is worſe or better.

Some of theſe added Matters are alſo in their natural Qualities more pernicious than nthers: the Soil always takes its Name from them; and according to their Nature it is ſuited to particular Purpoſes: a ſandy Soil doing beſt with ſome kind of Crops, a loamy with others; and in the ſame manner the reſt.

The Soil thus mix'd by Nature is to be the firſt Article in the Farmer's Conſideration; for on that will depend in a great Meaſure his Profits. It is eaſily examin'd; for often it ſhews it ſelf on the Surface; and it is the firſt Thing that appears on breaking up the Ground. It is thence called the underturf Earth; and alſo vegetable Earth, becauſe it furniſhes the needful Matter for the Growth of Vegetables, or Trees and Herbage of all Kinds.

Pure Mould is the lighteſt of thoſe ſeveral Subſtances which compoſe the Earth, and therefore even with theſe Mixtures it naturally lies above

above the others. It covers them in ſome Places to a greater, and in others to a leſſer Depth: and the Matter by which it is debaſed is uſually of the Nature of the Layer which lies immediately under it; whether that be Sand, Gravel, Stone, Clay or whatſoever.

This Mixture of the Soil with the under Layer or Bed, is often made greater by the Careleſneſs of the Huſbandman, who cuts too deep with his Plow, and turns up a part of the next Matter with it: but it is almoſt always mix'd, in ſome Degree, even where the Plow or Spade never came. Moſt probably the rich Mould, when the World was firſt made, was ſpread every where in Purity over the ſeveral other Beds; but at Noah's Flood they were in part mix'd together: and hence the Land is leſs fruitful than it was at firſt.

When the Soil is pureſt, it is always richeſt: and it is known to be of this Nature, by its blackiſh Colour, and its mellow Softneſs. Pure Mould is tender and pliant; ſhort, and ready to crumble and moulder to Pieces, from which it has its Name; and it is alſo called the Heart of the Land; and Live Earth, in ſome Places, becauſe it is the Strength of the Ground, and the Suſtenance of Herbage.

It follows naturally, that in Proportion as this Heart of the Land is leſs mix'd with thoſe barren Subſtances, it will be more fruitful; and contrarywiſe, where it is more debaſed, it will have leſs Fertility. It is plain alſo, that in the former Caſe, it will need leſs Dreſſing, and Manure; and in the latter more: ſo that the ſame Condition which makes it unfruitful, renders it alſo expenſive.

Now although this Condition of the Soil be moſt ſurely diſcover'd by opening and examining the Ground; it may in ſome Meaſure be diſtinguiſhed by the Surface, and by its Produce. We ſhall firſt therefore treat of thoſe Marks which are moſt obvious; and afterwards of the others, as they riſe in the Courſe of the Enquiry.

CHAP. I.

Of diſcovering the Nature of a Soil by the Situation and Surface.

THE Farmer naturally takes a View of the Land before he rents it; and even in this ſuperficial Examination he will make ſome Diſcoveries, from obſerving the Situation and the Surface.

In many Parts of England the Hills are in general more poor and barren; and the low Grounds more rich and fruitful; and this from a very natural Cauſe.

The fine Mould being light and looſe, is eaſily waſh'd from its ſtony or other Mixtures in the general Soil; and being carried off in ſome Degree from the hilly Parts, by the ſame Rains which ſeparate it, the Stony or other Remainder becomes ſo much the poorer. And from the ſame Cauſe, the Valleys are enriched beyond their natural Condition, becauſe the fine Earth, which is waſh'd from the Soil of the Hills, is carried to them.

This the Farmer in moſt Places experiences to his Coſt; the Crop being as much thinner on the Hills than in the Valley, as from his Labour and Expence he might otherwiſe expect it to be greater.

In ſome Places the Earth entirely wants this Soil, which is its proper Covering; and what ſhould in the Courſe of Nature be its lower Parts, lie naked. Thus Sand is ſeen upon the Surface of the Ground in ſome Counties, and naked Rocks upon the Hills in others. There is in theſe Caſes, no Mixture of Mould with the former, nor any Coat of it over the latter; neither does there grow ſo much as Graſs to cover them. The Farmer is here at once a Judge of the Land: and may declare it to be of ſcarce any Value; for entire Sand can only be fitted for Huſbandry at a great Expence; and bare Rocks not at all.

In ſome Parts of England there alſo riſe here and there Banks of entire Clay, and others of hard and pure Chalk, up to the Surface of the Ground. The Clay is often in this Caſe almoſt as barren as the Rock: but a ſhort Graſs will grow upon the Chalk.

Of theſe four Caſes that of the Rock is the only one quite unconquerable; nothing can make that fruitful: the other three may be brought to produce tolerable Crops, according to the Methods hereafter to be deliver'd; but the Expence is ſometimes too great for the Produce, tho' the Rent be ever ſo little.

In all theſe Caſes the Huſbandman may diſtinguiſh the general Nature of the Soil by its Aſpect on the Surface; we ſhall ſhew, in a ſucceeding Chapter, how he may judge of it by its Produce.

CHAP. II.

Of judging of a Soil by its common Produce.

WHEN the Farmer has examined a Piece of Land according to its Situation and Surface, ſo far as the latter appears naked; he is next to obſerve carefully its natural Produce; and the State of the Crops that are upon it: from theſe he will be able to form a Judgment not only of its Condition as to Heart and Richneſs, but of the particular Nature of each Part; and to know the Qualities as well as Value of the Soil.

Where he ſees the Graſs, Corn, and other valuable Growths look ſtrong and healthy, it is a Proof that the Soil is either rich by Nature, or capable of being made ſo by Improvement; ſo that his future Pains beſtow'd upon it will not loſe their Reward.

Even the free Growth of Weeds (unleſs it be of ſome garticular Kinds, as Fern, Ruſhes and the like, which betoken Barrenneſs for better Things) is a Proof of Goodneſs in the Ground. Care will deſtroy theſe; and the ſame Heart in the Land which before ſupported them, will give Suſtenance to the Crop.

Let him examine well not only how liable the Soil is to be over-run with Weeds, but of what

what Nature and Kind they are which grow upon it: for as there are ſome which ſhew Barrenneſs, there are others which betoken Fertility. And altho' ſome of theſe wild Herbs are common to many Soils, yet the greater Part are ſo far peculiar to certain Kinds, that the Nature and Quality of the Land may be known by them.

That Sort of Fern, which is named in Books Female Fern, and which the common People call Brakes, is a ſure Token of Barrenneſs. Its common Place of growing is on Heaths. The other ordinary Kind of Fern which is ſmaller, and is called Male Fern, is of a different Nature; it ſhews that the Soil is in that Part ſuited to the Growth of Trees, and it flouriſhes moſt under their Shade.

In the ſame Manner Clods of Ruſhes and jointed Graſs, betoken a poor, damp, and as it is commonly expreſſed, a ſour Land: but, in the Fen Countries, where a dark green ſhort Graſs grows among them; where the Ruſhes ſtand more diſperſed, not in ſuch Bunches, and where there are ſeen ſome yellow ſhort flag Leaves among them, it may inform the Farmer, that there is Peat underneath. It is by this the experienced Tenant judges about WHITLESEA, and in other Parts of the ISLE of ELY; where I have known them offer a large Premium for a certain Liberty of digging Peat upon the Land they were about to take, and that without opening the Ground.

Theſe already named are the Weeds which moſt of all betoken Barrenneſs; many of thoſe which will be ſpoken of hereafter, on the contrary ſhew the Land to have Strength and Richneſs.

There is the more Certainty in this Rule of Judging, becauſe the Weeds which grow on rich Lands, are in a Manner peculiar to them. There is no Plant whatſoever that is found in a Clayey, among a Stoney, or on a Chalkey Soil, that is not alſo to be found in ſuch as are rich and valuable: But there are many Weeds which are the natural Produce of rich, and many which grow in the ſame Manner on light Soils, no one of which was ever ſeen either upon a Chalkey, Stoney, or a Clayey Land.

The Evidence Nature gives this Way, of the Qualities and Value of a Soil, is however liable to miſtake, unleſs heedfully attended. The Farmer muſt take Care that he form his Judgment, not by thoſe Weeds that grow equally on bad and in good Soils; but if he ſees a Plenty of ſuch as grow only on good ones, he may then be ſure the Land is rich.

If he ſee a great Quantity of Fumitory, a low Weed with divided Leaves and purple Flowers; if ſeveral of the Kinds of Orach, grow free and ſtrong; and in general, if ſuch Weeds as are found in the mellow Beds of a well cultivated Garden, ſpring up in Abundance on the Ground, he may be ſure the Soil is rich, fruitful and fine; for not one of theſe will ever grow free and ſtrong on a ſtarved, or in a cold clayey Ground.

When he ſees the Corn Marigold, which the Farmers call the Golding, or Horſe Gold, in Abundance, he may be ſure the Soil is light and ſandy. It is a Land that will naturally bear Rye better than any other, but that may be brought to greater Value by Culture, and ſuited to every Species of Corn.

Where the Blewbottle is in great Plenty, and the Flowers are of a fine Colour, it ſhews the Soil is alſo light and looſe, but not without its natural Heart: this Weed and Cockle are a Proof of a light but good Soil, naturally fit for Barley and Wheat.

When the Flowers of the Blewbottle look pale and whitiſh, and the Herb itſelf grows meagre, it is a Sign of a ſtoney or chalkey Soil; or elſe that there is too much Sand in the Ground; for either of theſe Ingredients will occaſion that Change.

If there be a large Quantity of Wild Garlick, which is called in ſome Places Cow Garlick, among the Corn, it is a Token that the Land is of a clayey Nature. In HERTFORDSHIRE this Weed gets ſometimes into a ſtoney Ground, but that is not its natural Soil.

May-Weed, called alſo in ſome Places Wild Camomile, is in general a Mark of a loamy Soil; and the ſame Quality in the Land is ſhewn by the Wild Parſnip, which in BUCKINGHAMSHIRE and ſome of the neighbouring Counties they call Hog Weed and Swine Root. It is indeed the Parſnip not cultivated.

The Names of theſe and other Herbs, among the Country People, vary greatly. In ſome Places that of May Weed is given to Fumitory before mentioned; and the like Confuſion has been common with many others. It is therefore neceſſary to explain what is meant when they are uſed.

The Weeds which betoken a Soil altogether ſandy are generally low; and thoſe of a ſtony one, are commonly poor and ſtragling. Where there is a great deal of ſmall Scabious, Rampion with ſcabious Heads, and the little wild Madder, the Farmer may be ſure there is too much Sand in the Ground: and when he ſees the ſmall Throatwort and the like, he may know it is ſtony.

In the ſame Manner a chalky Soil is diſcover'd by its ſtarv'd Appearance, by the Scarcity and Lowneſs of the Weeds, and by the natural Growth of the Baſe Rocket, and the like Plants, which are ſcarce in other Places. The yellow Stonecrop or Wall Pepper, ſo common on our old Walls, grows alſo on the Ground in theſe Places, particularly on the chalky Hills of KENT.

CHAP. III.

Of judging of a Soil by the Growth of Trees.

WHEN the Farmer has obſerved the particular Kinds of Weeds; and form'd from them, and from the external Appearance of the Land, a general Notion of its Nature and Value. Let him obſerve the Growth of the Trees; particularly of thoſe in the Hedge Rows.

If they be tall, ſtrait, full branched, and well headed, he may be ſure the Soil is, as the Huſbandmen ſay, good at Heart; on the contrary, where the Trees grow irregular, low, crooked,

or ſtubbed, 'tis a Proof ſomething is bad at bottom.

In this general Rule he is however, in the ſame Manner as in the former, to admit certain Cautions. He is not to expect every particular Tree he ſees to be of this fair Kind; for Accidents will injure ſome: nor is he to imagine every Sort of Tree muſt thrive equally, to ſhew the Strength of the Soil.

There are very good Lands on which ſome Kinds of Trees will grow fair and fine, while others do not anſwer ſo well: this is confirm'd by frequent Obſervation; and it may be generally explain'd from the Depth of the Soil, and the Nature of the next Layer under it.

I was ſome Years ago in NORTHAMPTONSHIRE, at a Town called BRAMPTON IN THE ASH, where I ſoon found what had been the Occaſion of the Name. The Aſh Tree grows thereabouts with a Freedom and Excellence not known any where beſide.

Theſe Trees are all about that Place tall, ſtrait, and of even Growth, ſo that their Appearance ſurprized me: and on cutting them the Grain appeared yet more beautiful. It was ſoft, regular and full, beyond any I have ſeen.

At CRANFORD, in the ſame County, the Aſh grows no better than in other Places, but the witch Elm is remarkable for its quick Shooting, and its Beauty. In the ſame Manner, the Elm in many Parts of BUCKINGHAMSHIRE, and the Beech in SUSSEX, ſucceed beyond all other Trees.

The judicious Huſbandman from this may take his Direction what Trees to plant in his Grounds, preferably to others; Nature giving him the Inſtruction: but of this we ſhall treat in its proper Place. Trees are mentioned here only to inſtruct the Farmer to judge of the Soil by their Growth, as well as by its other Produce; and to inform him not to judge only by the general, but even by particular Kinds in this Caſe; for where any one Species of the Trees in the Hedge Rows thrives particularly well, he may be ſure the Soil of the neighbouring Grounds has a Heart.

CHAP. IV.

Of the ſeveral Kinds of Soils.

WE have deſcribed in the Firſt Chapter what Vegetable Mould ſhould be when pure; and we have nam'd the ſeveral Kinds of Mixtures from the Underlayers of the Earth which render it leſs fruitful; ſuch as Stone, Clay, Sand, and the like: We come now to conſider the Soils as differently mixed with theſe; and thence diſtinguiſh'd by particular Names.

There are Places, as already obſerv'd, where theſe ſeveral Subſtances, Stone, Clay and Sand, appear entire and unmix'd on the Surface of the Ground; but theſe, as there ſaid, are then barren: we are here to enquire into the Nature, not of theſe ſingly, but of thoſe Earths which are produced by a Mixture of one or other of them with the vegetable Mould. Theſe are what the Huſbandman calls Soils; and he names them according to the Subſtance which makes the Mixture. Thus they are called clayey, loamy, ſandy, ſtony, gravelly, or chalky Soils.

Theſe are their ſeveral general Names, by which they are known in all Counties, and which are Terms underſtood in all Places, becauſe they are founded in Reaſon, and upon Nature: but beſide theſe there are a great many others. To enumerate all would be to make this Part of the Work a Dictionary, not a Syſtem: however, the principal ſhall not be omitted.

The fine rich mellow Soil is call'd in LINCOLNSHIRE Moory Land, becauſe it is the Soil of the Moors and Fens. It is dark and crumbly. A Soil of much the ſame kind in the higher Grounds of LEICESTERSHIRE and WARWICKSHIRE is call'd Hen Mould, it is dark colour'd, light and ſpungy. This, as well as the other, is better for Paſturage than for the Plow.

What they call Hen Mould in NORTHAMPTONSHIRE and HUNTINGDONSHIRE, differs from this entirely. It is a rich but firm Earth of a blackiſh Colour, with Streaks of white like Mouldineſs; and the more there is of this, the richer is the Soil. We ſee by this double Uſe of the ſame Word, how eaſy it is to confound one Thing with another in Huſbandry: the Farmer muſt be careful to avoid this, or he can have little Improvement from what he hears or reads.

The clayey Soils are diſtinguiſh'd in HERTFORDSHIRE and BUCKINGHAMSHIRE according to their Colours, into the red, yellow, white and black: but red Land in HUNTINGDONSHIRE means quite another Thing, as will be ſeen hereafter.

In NORTHAMPTONSHIRE there is a Sort of clayey Soil, known by the Name of woodland Soil, becauſe it is the Sort of Earth on which the Woods uſually grow in that County. This is damp, tough, and ſad colour'd; it conſiſts of vegetable Earth with a large Mixture of black Clay; and there is always a Layer of ſound blackiſh Clay under it.

Sandy Soils are in moſt Counties diſtinguiſh'd alſo by their Colour; as the white, the yellow, and the red: but they have in ſome Places particular Names. All Soils have ſome Sand in them, even the richeſt: this may be ſeen by walking over them after a Shower of Rain: for tho' the earthy Part cover and conceal the Sand otherwiſe, yet the Showers waſhing it off, the Grains of Sand ſparkle and glitter at theſe Times.

A Soil is not however to be called ſandy, becauſe there is a ſmall Quantity of Sand thus mix'd among it; 'tis only when the Sand is predominant that it has this Name.

What is called a creachy Soil at COLLEYWESTON, and other Places in NORTHAMPTONSHIRE, is a ſandy Earth in which there are Bits of Stone, and Pieces of broken Shells that look as if they were calcin'd: as indeed they are by the Effects of the Sun and Air, and they tend greatly to improve the Land.

The Red Land as it is called about HALSTON, HASELBECH and ROWELL in the ſame County, is a ſandy Soil of a reddiſh Colour, with Pieces of a reddiſh Kind of Sand Stone among it, and ſometimes other Matters.

That

That which is called in LEICESTERSHIRE and WARWICKSHIRE a Kealy Soil, is a ſtoney Land compos'd of a good Earth, with a great deal of Stone or Slate among it like the Chippings of a Maſon's Yard. This in many Places bears good Crops of Barley when the larger Stones are clear-ed off..

Laſtly, what is called Chiſely Land in moſt of our midland Counties, is a kind of Loamy Soil, often very fit for Wheat, Barley or Rye.

As the Eye may at Sight diſtinguiſh the general Nature and Value of a Land by its Produce: the Plough at once diſcovers the particular Nature of the Soil according to theſe Diſtinctions.

The Moory Soil turns up eaſy and free: its Colour and its Mellowneſs readily diſtinguiſh it. The Clayey Lands are hardeſt to cut, and hang in tough Clods. The Hen Mould that is ſtreaked ſhews itſelf when the Sod is firſt open'd, for it is rarely ſeen afterwards. The Sandy Soils turn up eaſily and regularly; and the Stony more unequally. The loamy when they are pure cut eaſy, and the chalky are always dry and hard. That particular Kind of the Loamy Soil called Chiſely, has its Name from its falling off the Plough in Pieces like the cutting of a Chiſſel: for it is one of the ſhorteſt of the loamy Kinds. It is not ſo looſe as the ſandy Soils, which fall off from the Irons like Bran or Saw-duſt; nor ſo tough as the Clay, that riſe in long Flakes; but breaks in ſmall Pieces. When a Land riſes in this Manner to the Plough, the Farmers in many Places ſay it brackles, and they look upon it to be a good Property.

CHAP. V.

Of Clayey Soils in general.

CLAYS, tho' diſtinguiſh'd according to their Colours, under the Terms of red, yellow, black and white, and called in particular Places under their different Appearances, by a Variety of Names, yet ALL agree in their general Nature, and may be conveniently firſt treated of together.

They differ from all other Soils in that they are tough, wet, and cold: and in Proportion as they are mix'd in greater or leſſer Quantity in the Lands, they give them thoſe Properties in a greater or leſſer Degree.

Some of the Kinds are indeed ſo much tougher than the others, that an equal Mixture of them does more hurt. Thus the red Clays debaſe Lands more than any other Kind: the yellow are next in Stiffneſs and Coldneſs to theſe; the black are leſs wet and tough than either of the former, and the white leaſt of all. However, the yellow in a ſomewhat larger Proportion, will do equal Miſchief with the red in a ſmaller, and ſo of the reſt: the Difference as at firſt obſerv'd, being more in the Quantity of the Clay in the Soil, than according to the particular Kind.

The Improvement of all Soils depends in a great Meaſure upon the breaking them, by which Means their Parts are more expoſed to the Sun and Air, and are made more fit to receive the different Kinds of Seeds.

As the clayey Soils are of all others the moſt tough, they moſt of all require this Care. We know that the Effect of Fire is to reduce this tough Earth into a looſe crumbly Matter: And whatever Fire will do on theſe Occaſions, the Action of the Sun and Air will alſo perform, only it requires more Time. Oyſterſhells that have lain a great while on the Sea Shores are as perfectly calcin'd by the Sun and Air, as if they had been in the Fire. And in the ſame Manner thoſe Shells which are found in Marle, and other Earths, when they have been a while ſpread upon the Ground, grow ſoft and crumbly. It is the ſame with Clay: the Sun and Air will take away its tough Quality, as the Fire does: and frequent Plowing meliorates clayey Soils, by turning up the Clods in different Poſitions to the Sun and Air, and by aſſiſting the Operation in breaking them to pieces.

This is the Way wherein freequent Plowing operates upon a clayey Soil, and the Farmer who tries it will never be deceived in his Expectations.

All Clay Lands are known by theſe Qualities. They hold the Water that falls on them; and when well wetted, they are a great while before they dry: in the ſame Manner when thoroughly dry, they are not ſoon wetted. In a dry Seaſon the Land cracks in Chinks. If it be plow'd when wet, it ſticks to the Plow like Mortar; and in a dry Seaſon the Plow tears it up in great hard Clods, which are all Clay at the Bottom. For this Reaſon where the Coat of Soil is not thick, the Farmer ſhould not plow deep, for he will then injure his Land by mixing the Clay among it.

All the clayey Soils require a great deal of Induſtry and Care, as well as Knowledge, in the Dreſſing and Management: but when the Toughneſs is got the better of, ſo that the Farmer can get his Grain into it, and ſee it well cover'd, it very often yields large Crops. The ſtiffeſt clayey Soil I have ever ſeen in ENGLAND, is about THRAPSTON in NORTHAMPTONSHIRE; and yet with the thorough Management they uſe there, it is one of the richeſt Lands in the Country.

Having thus treated of the clayey Soils in general, and ſhewn the great Neceſſity of their careful Culture, we ſhall proceed to examine them particularly, and deliver the ſeveral Methods which have been found moſt ſucceſsful in treating the ſeveral Kinds.

CHAP. VI.

Of red clayey Soils for Tillage.

THE rediſh Clay, which gives the Colour and Name to theſe Soils, is the tougheſt and coldeſt of all the Kinds; and requires the moſt Pains in the Huſbandman to ſubdue its Nature.

It is frequent in its pure and entire State in the Counties of WARWICK, LEICESTER, YORK and NORTHAMPTON: they have alſo their Share of

of it in Buckinghamshire: in all these Places it is perceived plain enough in the Roads; which are stiff and deep in Winter, and are full of great Cracks in Summer.

It lies in the same Places under the Soil in all their Fields, and is in a greater or lesser Degree mix'd with it every where thereabouts. The mix'd Soil over the Bed of pure Clay is generally of a considerable Thickness, which is very happy for the Farmer, as it gives him the Liberty of plowing deep, which this Land requires more than any other.

The first Method for the improving this Kind of Soil is, by frequently repeating these deep Plowings to break and seperate the Clods over and over, as the Sun and Air calcine them.

To this the Farmer is to add the Assistance of Dressings. And it is the particular Quality of this Clay, that it will receive all kinds of Manures, and be improved by them: but then the Labour is to be equal to the Expence, for without the frequent plowing already mention'd, nothing will take Effect upon it.

Dung does not readily mix with this Sort of Soil; but when it is well plow'd in, 'tis of great Service. This however is not the Kind that agrees best with it; in Northamptonshire they manure it with Lime to some Advantage; in Hertfordshire and Buckinghamshire they use Soot and Ashes; but that which agrees best of all with its Nature is Chalk. This is now the general Practice; and the Farmers in most Parts of England begin to find the Advantages of it.

The young Husbandman must not be disheartened at the Expence of this Sort of Dressing, or the Labour of such frequent Plowings; for he will be sure to reap the Benefit of it: it is much more chargeable to dress a Piece of the red clayey Soil, than any other whatsoever; but then the Advantage lasts long in Proportion: a Field of this Soil, once well dressed, will keep in Heart fifteen or sixteen Years.

Indeed it may be remarked of the clayey Soils in ganeral; and most of all of this in particular, that altho' no Ground is so stubborn or so barren when neglected; none has so many or so great and good Qualities, when it has been thoroughly wrought in the above described Manner.

Perhaps it may be said with Truth, that the more tough and stubborn these Soils are, the richer they prove when they are thoroughly subdu'd. Of this I shall give an Instance which has fallen within my own Knowledge.

There is near Cawcote in Northamptonshire, a Piece of small Extent, the most tough and untractable perhaps in that County, or in the whole Kingdom. This is indeed almost an entire dusky Clay. For a great many Years the Farmers all neglected it, and it produc'd almost nothing; at length about thirteen Years ago a young Man dress'd it thoroughly, and he soon found the Advantage; which continues to this Time. For with a moderate Care and Industry, it is now the richest Piece of Ground in the Country.

This is an Example the young Farmers in general should thoroughly mind: not to be sparing in Cost, much less in Labour, upon a Sort of Land which never fails to return them the greatest, and the most lasting Advantages.

When this Kind of Soil is redest, it is most clayey: where of a duskyer Colour it frequently, tho' not always, has more of the right vegetable Earth among it, In the latter Case it yields the larger Crop with a little dressing; but when the former is well manag'd it greatly exceeds it: the Crops of this Soil may be properly called the Rewards of Industry.

The clayey Soils have their Advantages and Disadvantages in respect of others with Regard to their Crops; and those of the red Kind most of all, these being the most considerable.

In the first Place, the Crop upon a red clayey Soil is later in the Year before it arrives at its Perfection, than that which is sown with the same Circumstances upon a sandy, or indeed on any other Land. It is from this the clayey Soil has obtain'd among the Farmers, the Name of the coldest of all Soils.

I have found also by frequent Observation, that these Soils are coldest of all where the Layer or Bed of pure Clay that lies under the Soil is thickest. This is known when Pits are open'd for this Clay for various Uses, for which it is excellent, and which shall be enumerated hereafter. And where it runs very deep, the Harvest is always naturally later in Proportion.

It is not a wonder that a Soil should be very cold which is almost continually wet: a Piece of such Land certainly is more affected by cold than such as is dry; as we see by this that when a sharp Frost comes on at once in a dry Season, it frequently does little Harm to the young Growths of the Garden or the Field; but Frost after Rain is destructive.

The Damage by Frost is not so immediate in a clayey Soil; but when it has taken hold it is more lasting. A slight Frost does not penetrate Clay so quickly as it does other Earth: but when a clayey Soil is once harden'd by the Frost, it remains longer hard than any other.

When this red clayey Soil is well wrought, Wheat succeeds excellently upon it. Barley sometimes yields a good Crop, but not constantly, for it depends on the Season; if that prove dry the Barley does well; but if not it comes to little; for this Soil holds the Water a great while, and Barley cannot bear a great deal of wet to lie about the Roots.

Beans succeed extreamly well in this Earth, for they will bear a great deal of Water, nay they require it: for in dry Seasons and on a loose Land, they yield nothing in Comparison of their Produce on these Soils. Beans require a great deal of Nourishment, and this red clayey Soil is the richest feeding Land we have when well prepared.

It is not wonderful that proper Crops should grow well upon a Land which holds so much Water: for we see that Mint, and many other Herbs, will grow in Water where there is no Earth at all.

Notwithstanding the Advantages the red clayey Soil has over many others when carefully manur'd; yet there are Accidents also to which it is liable; and which are owing to its Original Nature,

Nature, of thefe I fhall recount fome few which I have feen.

If the Seafon prove driping for a long Time together, and their fall a great deal of Rain in MAY, the Crop upon this Soil always fuffers. The Beans bear it beft: the Wheat becomes ftunted and pale, and the Barley turns yellow, and if the Seafon continue wet they don't well recover.

In a wet and frofty Spring, the Crops of Peafe on this Soil are alfo apt to fail. The fure Sign of this is the green Shoot turning red: and it is confirm'd by Experience, that in this Cafe it never recovers. Upon other Lands the Shoot will get this Caft in a bad Seafon; but when once it happens in a red clayey Soil all is loft.

When this happens, it is beft to know what one has to expect. As the Crop will never come to itfelf, the right Method is to plow it up at once, and fow the Ground with Oats.

It was for the Reafon of this Accident I did not mention Peafe among the Crops that fucceed beft on this Soil. But befide Wheat and Beans, as alfo frequently Barley, it is excellent for Clover; and no Land fucceeds better with Turnips.

As to the Accidents I have mention'd as attending this Soil more than others, they are all owing to the Toughnefs of its Original Nature; and I have from many Years Experience, found that they happen always moft in Proportion as it has been leaft drefs'd. I have obferv'd before, that it is in itfelf a very bad Soil; but that it becomes very rich and profitable by being well manur'd. And if I may fpeak what I have feen by my own Experience, it is that thofe Accidents I have named, are all owing to the imperfect manuring of this Soil; for I have feen feveral Years that my Crops have all ftood well upon a Field of this Nature, when my Neighbours loft theirs, or they produced very little: and the only Caufe of this was, that I fpar'd neither Chalk nor Hufbandry; while they were frugal of both: and oftentimes my good Succefs and their Lofs, have happen'd feveral Years after my laft Chalking of the Ground.

My Advice therefore to the young Farmer, who has a Piece of Land with this Soil upon his Hands, is.

Firft, not to fpare either Labour or Expence upon it in the Beginning, for all this will be return'd to him ten-fold. Let him plow it thoroughly and often, and take Care that the Plow cut deep. Let him employ a careful and honeft Plowman that will mind his Bufinefs, not an idle Boy, as is too often done. And let him go over the Land frequently himfelf to fee that it is well cut up, and well broke in every Part.

In the fecond Place, let him beftow Chalk enough upon it, and fee it be worked well in; or if Chalk cannot be had, let him ufe fome of the other Manures juft mention'd. When this is thoroughly done at firft, common Care and Induftry will ferve afterwards: and from this he will have a Soil, which inftead of holding the Water to chill his Crops while young, will let the wet when it is too much, below the Roots; and will always detain enough.

Thirdly, Let him depend chiefly upon his Wheat: for that Grain upon a red clayey Soil thus manur'd, will never fail him. He may alfo be fure of Beans, Turnips and Clover, for thefe never fail. He may in dry Seafons ftand a fair Chance for Barley: but Wheat is the fure and certain Commodity for this Soil.

Laftly, when he has thus got his Land into good Order by his Induftry and Expence, don't let him drain it of its Heart again by Covetoufnefs or Folly. Let him not draw away its Strength by crofs croping, or too frequent fowing. Moderation is the Rule of all Things in this Life. There is no way be poor fo quickly, as the Defire of growing rich too faft.

CHAP. VII.

Of red clayey Soils for Paſturage.

THE Soil which is cover'd with a Turf, and that which has been many Years open'd by the Plow, will be found to differ a great deal when brought together, altho' they lie in adjoining Fields, and are in their Original altogether the fame.

I remember about eight Years fince to have been furpriz'd by this Obfervation in BUCKINGHAMSHIRE, but I have fince repeated it with the fame Succefs in other Places; where the Earth has been to Appearance very different in a plow'd and a Pafture Ground, though only a Hedge parted them. I mention this Circumftance, that no Miftake may happen in judging of this Soil, but that the Farmer may know it to be the fame when he fees it. In the BUCKINGHAMSHIRE Experiment, I took up a Piece of a red clayey Land from a Field not well manur'd, which was clofe, hard, and high colour'd: after this cutting thro' the Turf, in an adjoining Pafture, I took up a Piece of the Soil there, which altho' rediſh and clayey, yet was lefs compact than the other, and of a darker Colour. The Cauſe of this is, that in Paftures the Soil keeps more entire, and has its due natural Portion of vegetable Earth among it: whereas in plowed Lands, this is in a great Meafure wafh'd away, and taken up by the Crops, fo that the clayey Part remains more viſible.

When the Farmer therefore finds under the Turf in his Paſture, a Soil that is like that of his red clayey Lands, only fomewhat darker and mellower, he may be aſſur'd that it is the fame in its Nature; and would appear the fame with the other after a little plowing.

This Soil when there is a due Proportion of vegetable Earth among it, is excellent for Paſturage. It has an unconquerable Heart, and the Produce is ſtrong. Where it is too near entire Clay, it muſt be aſſiſted by dreſſings.

I have obſerv'd throughout all BUCKINGHAMSHIRE, that where low Grounds have this red clayey Soil, they never fail to produce great Quantities of Graſs, and that excellent in its Kind, with little or no Manure. The Reaſon is, that the Rains bring down the light fine Earth from the higher Lands; and the Overflowings of the Rivers leave their fine Mud upon them, whence they are render'd fertile in a ſurprizing Manner.

This may be a Leſſon to the Farmer, that the beſt of all Manure for this Soil in Paſture Grounds, is the Mud taken from the Bottom of Waters. Nature is the beſt of all Inſtructors. This is the Practice every where in Buckinghamshire: They drag up the Mud from the Bottoms of their little Rivulets, and it enriches their Paſtures that have this Soil in a ſurprizing Manner.

The Reaſon why this red clayey Soil receives more good from the Waſhings of the Hills, the Fall of Rains, and Overflowings of Waters in Paſturage than any other Kind, is, that it retains the fine vegetable Earth which is brought upon it; the fineſt Part of which gets through the others. Thus its Toughneſs is an Advantage.

Even pure Rain Water as it falls from the Clouds, contains a great deal of this vegetable Earth, as it may be prov'd by Experiments. Now when this falls upon a looſe Soil, the Water paſſes through, and this pure Earth, which is the true Nouriſhment of Vegetables with it: but when it falls upon this tough Soil, or is otherwiſe brought upon it, the Water is detain'd a great while, and this fine Earth with it; and the Earth is kept when the Water has by Degrees got through. So that all which comes is preſerv'd for the Benefit of the Herbage.

This is the Reaſon why Paſtures that have a red clayey Soil are always fruitful, in whatſoever Situation; but moſt when they lie low: as Experience in all the Counties where I have been confirms.

What they call Woodland in Northamptonshire, which, as before obſerv'd, is a red clayey Soil, tho' in ſome Places render'd duſky by Accidents, is alſo very fruitful in Paſturage.

I don't wonder therefore, that in many Parts of the laſt named County, the Farmers have a great while prefer'd the Paſture to the Corn Lands in a great many Places; and that large Quantities of what was heretofore Tillage Ground, is encloſed and converted into Paſture. For the red clayey Soil is very frequent there; and this requires a great deal of Labour and Expence in Tillage, but very little for Paſturage: there is alſo a great deal of Hazard in the former Way, as obſerv'd already concerning the Crops of Barley and of Peaſe: whereas when it is laid down to Paſturage, there is no Hazard at all.

But altho' I do not wonder at this Cuſtom among the former Northamptonshire Farmers, yet the carrying it too far is a Practice not to be commended. For there ſhould aways be a Proportion preſerv'd between the Paſture and Tillage Land; that the Dung of one be enough to ſupply the other. Of this I ſhall ſpeak more largely in its Place: it is only hinted here, leſt haſty Youths ſhould ſeize on the Expedient of converting Arable Land to Paſturage, without ſeeing Conſequences.

For Proof of what I have advanced, that there are few Soils better than the red clayey Land for Paſturage, I ſhall obſerve, that the fineſt and richeſt Knot of Paſtures I have ever met with, lies about the Point where the Counties of Leicester, Warwick and Northampton meet, particularly in the Lordſhips of Ashley, Eltinoton and Thurnley; and in all theſe the Soil is a red clayey one, only render'd duſky by the greater Mixture of vegetable Mould, as it has been obſerv'd already there always is in Paſtures.

I have thus endeavour'd to ſhew the young Farmer the Nature of this Soil in Paſtures, and its Value: as alſo to give him the Reaſons of it: becauſe I know when Things are underſtood, they are better remember'd.

The Advice I have to give him is this. Not to be too haſty in making Changes from Tillage Land to Paſture, or from Paſture to Tillage, becauſe a great deal is to be conſider'd: let him in general leave Things as they are in this Reſpect; at leaſt till he has very well weigh'd them. Let him ſee that he keep up the Proportion between his Arable and Paſture: and let him not be haſty to lay down plow'd Lands into Paſture, to ſave Expence and prevent Hazard; nor on the other Hand, to turn up good Paſtures for Corn Land, for the Sake of the firſt Crop. That will probably indeed be good, becauſe of the Quantity of fine Earth originally in the Soil; but when this is exhauſted, he ſees at what an Expence of Labour and Manure, he muſt ſupply its Place; for the Soil is ſoon drain'd of this its natural Richneſs, and without the Aſſiſtance of Art afterwards will do little. There may be Occaſions of making theſe Changes to Advantage, but let it never be done haſtily. There can never be more Room for Conſideration.

CHAP. VIII.

Of red clayey Soils for Trees.

THE Planting of Trees, and the Manure of Paſtures, are Subjects to be treated of hereafter in their Places: we are here only conſidering the Nature of particular Kinds of Soil, and they are nam'd barely to ſhew how they ſuit them.

Now the Conſideration of Land, in reſpect of Trees, muſt be carry'd deeper than the Soil. This Term I have ſhewn takes in no more than the upper Covering of the Earth: but Trees ſtrike their Roots deeper, and there ſeek their Nouriſhment.

However, as this Soil generally runs thicker than moſt others, and as it commonly has a Bed of the ſame red Clay under it, of which it principally conſiſts; it is proper in this Work, wherein nothing is intended to be omitted that is uſeful, to conſider the Soil in this Reſpect.

All Trees do not equally agree when young with all Soils, as is plain from Experience; nor do they thrive equally, when more grown, upon all Lands. This may be explain'd in the firſt Reſpect from the Richneſs, or the Poorneſs of the Soil or upper Earth itſelf: and in the latter, from its Bottom. Some Trees pierce deep into the Ground with their Roots, others ſpread them far and wide, under the Surface, at a ſmall Depth: of the firſt kind is the Oak, and the Aſh is of the latter. The Aſh therefore may do in a Place where there is ſome little depth of good

good Earth, and the under Layer is Rock, but the Oak cannot.

This familiar Inſtance may ſhew, in what reſpect this red clayey Soil is fit for Trees; and in what it is not: we ſee plainly it is good for ſome Kinds, and not for others.

The Aſh grows well at BRAMPTON in NORTHAMPTONSHIRE, becauſe the Soil is light and rich: but in ELTINTON Hundred, in the ſame County, where the Paſture is alſo rich, the Aſh does not thrive at all, the Soil being of this clayey Kind. On the other Hand, the Oak grows beautifully in the latter Place, which in the other fares but indifferently.

The red clayey Soil therefore is excellent for the Oak, but not well for Aſh. And in general, from the ſame Reaſon, it will ſucceed with all thoſe Trees which have Tap Roots, that is, long ſingle Roots which pierce deep into the Ground: and but indifferently with thoſe which have ſhallow and ſpreading Roots, that ſtretch under the Surface. Which Trees belong to each of theſe Claſſes will be ſhewn hereafter.

The ſhallow rooted Trees ſucceed beſt where there is a richer upper Coat; but the deep rooted ones find Advantage where the under Layer is ſuch as they can penetrate, and is capable of affording ſome Nouriſhment.

One Advantage of the red clayey Soil for Trees is, that whatever Kind once takes in it will continue to thrive; whereas in others, there is often a promiſing Appearance at firſt, and they die off afterwards; and if the Growth be ſlower in this coarſe Soil than it is in ſome finer, the Timber is always firmer, ſounder, and better in its Kind.

The Trees which ſtand well upon this Soil always grow ſtrait and lofty, becauſe of the Depth of the Ground; whereas thoſe which ſhoot apace, from their ſtanding in a rich Soil with a bad Bottom, grow ſtubby afterwards, ſpreading their Tops inſtead of riſing to a Height.

Thoſe Trees which ſuit this Land alſo, may be planted ſafely in Places where others cannot, for they never hurt any Thing that is ſown in the adjoining Land. Trees which ſpread their Roots ſtarve the Growths that are near them; but theſe draw their Nouriſhment from greater Depths, and conſequently hurt nothing.

Without therefore entering farther in this Place into Subjects that muſt be treated at large elſewhere, my Advice to the Farmer is, that when he is to plant upon this Soil, he look about the Grounds, and ſee what Trees thrive beſt, and ſelect thoſe Sorts for his Purpoſe. And he may account it one of the Advantages attending this Land, that it is not hurt by the Trees which are planted in it: as all others more or leſs are.

CHAP. IX.

Of yellow Clayey Soils for Tillage.

THE yellow Clay of ENGLAND is in its Nature more nearly ally'd to the red than any other: and is next to that the moſt frequent. It is as univerſal in ſome Counties, as the red is in others; and is ſo much of the ſame Compoſition, that a great many of the Rules laid down in the preceding Chapters hold true here: but as Chalk is the beſt Manure for that, Marle, where a proper Kind can be had, is for this.

In this Place it is neceſſary to caution the Farmer, that he rightly and exactly underſtand what is meant by a yellow clayey Soil: and particularly, that he obſerve the Difference between that and yellow Loam, to be deſcribed hereafter in its Place: otherwiſe he may hurt himſelf by the moſt ſtrict Obſervance of our Rules, by employing his Manures upon a wrong Soil.

Yellow Loam is a mix'd Earth, compos'd of Clay and a great deal of Sand, with very little of any other Matter. But the yellow clayey Soil is a Mixture of yellow Clay with a greater or leſſer Portion of vegetable Earth, reſembling greatly the red clayey Soil, except in Colour, and having no other Sand in it than the general ſmall Quantity which is found in almoſt all Soils.

The yellow Loam as will be ſhewn more fully hereafter, is crumbly: the yellow clayey Soil is tough. One breaks off in little Parcels from the Plow; the other riſes in long tough Flakes.

After having thus diſtinguiſh'd exactly what the yellow clayey Soil, of which I am about to treat, is, I ſhall conſider it as the other, with reſpect to Tillage, in the preſent Chapter; and as it is concern'd in Paſturage and the Growth of Trees, in the two ſucceeding. My Deſire is, that the Farmer ſhould perfectly underſtand his Soil, before he enters on any other Part of his Profeſſion, for it is the Foundation of all.

The yellow Clay, of which this Soil principally conſiſts, is oftener found pure and entire than the red: and when it is ſo, its Toughneſs in wet Weather, and its flinty Hardneſs in dry, render it very difficultly manag'd.

In the clayey Soil of this Colour there is mix'd more or leſs of mellow Earth with the Clay; and accordingly it is more or leſs fruitful in the firſt Tillage; and requires greater or leſſer Expence in dreſſing afterwards.

The ſtiffer this Soil is, the more barren it is; and the more brittle the more fruitful: for Reaſons given already. It is moſt ſtiff where there is the leaſt Mixture of Earth with the Clay; and, in Conſequence, it is the moſt fruitful, where the Mixture of Earth is largeſt.

This is ſeen in Nature, and this Art is to imitate, where the Mixture of Earth was not originally enough in Quantity; or where it has been waſh'd away by Rains, or drawn off by frequent Crops, for they conſume it; the Want is to be ſupply'd by ſome Manure which will break its Stiffneſs; or by the Plow, the Air and Sun, which calcine it till it is crumbly: both theſe join'd together render it laſtingly fertile.

What in many Places they call Hazel Mould, is a Mixture of yellow Clay, with more or leſs of a blackiſh mellow Earth. This makes the beſt Soil, that is naturally form'd of the yellow Clay; and is excellent for Wheat and Rye: it will alſo bear other Crops well, but theſe two beſt.

The Improvement of the common yellow clayey Soil, which is in its own Nature much poorer than the hazel Mould juſt mention'd, is to be begun by frequent and deep Plowings. When the Clods are by this Means broke, and the Matter render'd leſs crumbly, the Manures are to be apply'd. I have found by Experience, that this Soil takes Manure better than the red: and I have diſcover'd by repeated Trials, that nothing is better for it than Chalk. Marle alſo is excellent, as will be ſhewn hereafter. Aſhes, Soot, and even Sand, are uſeful alſo; and Dung, after the firſt Dreſſings, will mix well with it.

In Oxfordshire they mix Chalk and Aſhes to great Advantage.

In Staffordshire, where this Soil is frequent in the common Fields, they ſow it two Years, and let it lie fallow the third. They lay it in Ridges, or otherwiſe, according to the Condition; and make their Fallows toward the latter End of March. They plow it a ſecond Time about three Months after, or a little ſooner; and before this, they dreſs it with Cow-dung, or Horſe-dung, except when they fold it with Sheep, then it is immediately ſpread and caſt under Furrow with the Plow, before the Sun and Rain exhauſt and weaken it. Ten Weeks after this, that is toward the End of Auguſt, they plow it again to kill the Weeds; and to turn up the Manure. About the Week before Michaelmas they plow for ſowing, and then the Manure is again turn'd, and falls upon the Seed with the fineſt Part of the Land.

They ſow Wheat upon the Land after this Dreſſing, and afterwards Beans, with both which the yellow clayey Soil excellently agrees after this Preparation. This is the Staffordshire Practice in common Fields.

When they have the ſame Soil in their enclоſed Grounds, they manure it with a light kind of Marle. If they ſhould put a clayey Marle upon this Land, it would be only adding Stiffneſs to Stiffneſs; but they have a greyiſh Kind in that County, which crumbles after the leaſt Rain, and this they uſe for theſe Purpoſes: with this Dreſſing it will yield good Graſs after eight or nine Crops.

Now tho' this Practice be not altogether the beſt that can be uſed, we ſee the Effect it takes; and therefore much may be gather'd from it.

They plow it four Times for Wheat. This, with the Effect of the Air breaks, and makes it looſe and crumbly. The Rains then ſoak into it, inſtead of lying upon it, or running off without Benefit, and leave behind them the fine Earth they contain.

The ſame Purpoſe is forwarded alſo by their laying it in Ridges, becauſe more of it is in that Situation expoſed to the Air and Rain. After this, once plowing does for Beans, becauſe the Earth is already improved by theſe repeated Plowings; and becauſe Beans do not require ſo fine an Earth to cover them as Corn.

The Farmer ſeeing Things in this Light, will underſtand the Reaſons of his Succeſs, or Failure in every Article; and will be enabled to improve his Lands, and enrich himſelf, upon the Principles of Reaſon.

He will ſee the great Diſadvantage of the common Field Management, and the great Benefit of the Dreſſing given in the Encloſures in the ſtrongeſt Light. In the firſt Method every third Year is loſt. Nor is that all, but they loſe a great deal of the Advantage of the ſecond Year: For in the other Way, a good Huſbandman after his Crop of Beans, Peaſe, Oats, or Barley, has a Crop of Turneps or of Clover.

Inſtead of this great Loſs, the enclos'd Land of the ſame Kind manur'd with the grey Marle, yields eight or ten Years Crops ſucceſſively; and at the End of the Plowing when it is laid, to gain freſh Heart, it yields good Graſs, and no Time at all is loſt. Nor is it really neceſſary to let it lie ſtill at all, for if they keep marling it conſtantly, they may plow conſtantly: the Dreſſing ſupplying Nouriſhment for a new Crop, as ſoon as the old one has exhauſted the former.

Upon the whole of what has been ſaid of the Management of this, as well as the other clayey Soils, my Advice to the young Farmer is, that he conſider if he have an encloſed Field of this Soil in his Hands, what Kind of Manure he can beſt command, and at leaſt Expence: for this is a Conſideration that will weigh againſt any other.

Let him begin by plowing deep and often; and let him lay up the Land in Ridges, obſerving to place the Ridges Eaſt and Weſt, that the Sun may have fuller Effect on them.

If there be Marle in the Neighbourhood, let him examine whether it be fit for the improving of Clay in this Manner. Firſt of all let him examine it in his Hand; if it be firm and heavy, it is not fit. The lighter always the better for this Purpoſe. Then let him throw a Piece of it into a Bowl of Water; if it begin preſently to crumble to Pieces of itſelf, and in a ſhort Time fall to a kind of Powder, it is fit for the Purpoſe; but if it continue in a Lump, and the Water have little Effect on it, 'tis not for his Uſe for this Kind of Soil. I ſhall ſpeak more largely of Manures hereafter, ſo this may ſuffice for the preſent Occaſion.

If he have a proper Marle at Hand, let him lay it on in Plenty for the firſt Dreſſing; and repeat it in moderate Quantities afterwards: If Marle of the right Sort be not in the Way, let him uſe Chalk. This does not take ſo quick an Effect, becauſe it does not get into the Body of the Clay ſo ſoon, but the Expence and Labour are very well repaid, becauſe the Benefit is as laſting nearly in this, as it is in the red clayey Soil.

If the firſt Manure be Marle, he may continue the ſame without any Addition; but if Chalk, he will do well to give the Aſſiſtance of other lighter Manures occaſionally. Saw-duſt, when it can be had in Quantities, is a very great Promoter of Fertility in this Land. It acts in the ſame Manner as the decay'd Stalks of Plants, than which nothing is richer.

In ſome Places where other Manure cannot be had, Sea Sand may be uſed for the Improvement of the yellow clayey Soil; and it is to be laid on in very large Quantities: this may ſeem ſtrange Advice to the Farmer in ſome Counties, where ſuch a Thing was never heard of, for every Thing appears ſtrange at firſt; but it is

a Practice founded on Reaſon: the Cauſe of the particular Barrenneſs of theſe clayey Soils, is the Toughneſs of their Subſtance; and Sand breaks that Toughneſs, and gives Way for the Rains to get into their Body. Farther Loams are fruitful, as will be ſeen hereafter; and as the practical Farmer well knows Loams are only Mixtures of Clay and Sand. Nature has made the Mixture in theſe Places, and why may not Art and Induſtry imitate her.

By large Dreſſings of Sand, a clayey Soil may be turn'd into a loamy one for ever; and then an Addition of ſuch Manures as we ſhall afterwards order for Loams is uſeful. Nor is it a Wonder that Sand ſhould in this Manner meliorate Clay Ground; for Clay is uſed in the ſame Way as a Manure to Sand, of which more hereafter; and in that Caſe it does the ſame Thing.

Aſhes which are a very good Manure for yellow clayey Lands, act in a double Way, both as Sand, and by their other Qualities; warming, as well as opening the Land: and after the more ſubſtantial Dreſſings, Soot is an excellent Manure. Nor is burning to be forgot for the Improvement either of this, or of the red clayey Soil, for it breaks their Parts in a ſurprizing Manner, rendering them not only fruitful in themſelves, but converting them into a Manure for other Lands.

CHAP. X.

Of yellow clayey Soils for Paſturage.

I Have obſerved of the red clayey Soils, that they are very rich in Graſs when they lie low, becauſe they retain the Advantage brought them by Waters. But Experience ſhews this is not ſo much the Caſe in the yellow, for when they are in a low Situation, they are too damp for any good Produce.

The Reaſon of this I take to be, that their Subſtance is more compact than the red, and they do not let in that fine Earth which comes with Rain or otherwiſe, and which mellows and enriches the red clayey Soils in this Situation.

For a Proof of this I have obſerved upon examining, that the yellow clayey Soil contains leſs of the vegetable Earth in general in its Mixture than the red: that is, it comes nearer to entire Clay. A Piece of this Soil taken from under the Turf in a Paſture, is ſeldom richer than a Piece taken from a plow'd Ground of the ſame Soil. From theſe Obſervations, I believe, we may fairly judge, that the yellow clayey Soil is for the Generality, much poorer than the red. And this is the Reaſon Marle is ſo excellent a Manure for the yellow clayey Soil, becauſe it diſſolves into ſo fine a Subſtance, that it mixes with the Clay, and ſerves in the Place of that Earth, which Nature has denied in the Compoſition, breaking the tough Texture of the Soil, and letting in Rains.

But tho' low Grounds that have a yellow clayey Soil, do not uſually produce ſo good Graſs as thoſe of a red: yet this Kind is upon an Equality with the other when it lies dry. This is a very common Soil in the high Paſtures in BEDFORDSHIRE, and the Graſs is excellent.

As the Soil may be judged of in general by its natural Growth, ſo it may alſo with great Juſtice in particular Places. It is always a Mark of good Paſture Ground, that a great Quantity of Cowſlips naturally grow there; and there is no Soil that produces ſo many or ſo ſtrong as this! nor is it apt to be over-run with Weeds, except Thiſtles, which are known to be the natural Produce of all Soils that are clayey, and have a good Heart.

The Farmers in BEDFORDSHIRE obſerve, that it is always a good Paſture to feed Cows upon, where there are Abundance of Cowſlips, and I have obſerv'd in many other Counties, that there is no Paſturage ſo well agrees with that Animal, as where the Ground is of this yellow clayey Kind.

The greateſt Diſadvantage of theſe Paſtures, eſpecially when they are on the Slope of a hilly Ground, is, they are apt to be moiſt in Winter. In WARWICKSHIRE they prevent this by diging many deep Trenches thro' them. Theſe receive the wet and carry it off by Degrees, as may be known by the continual dribling at their Openings. By this Means they keep the Paſture Ground, though of this Soil, ſufficiently dry at all Seaſons.

It is always good in Paſtures to have a firm Bottom that will detain ſome Moiſture; and this is one Reaſon why the Paſtures on a yellow clayey Soil are good: for they have uſually a pure yellow Clay for the under Layer, and that is one of the firmeſt of Earths.

A Paſture that has a yellow clayey Soil, and that lies high, will need frequent feeding or mending, whereas thoſe in a lower Situation, are dreſs'd by Nature, as obſerved before: but then the Hay of the beſt low Lands, is not to be compared with that of theſe higher Grounds.

I have obſerved in many Inſtances, that the fineſt Hay I have ever ſeen, has come off of high Grounds, where there has been a yellow clayey Soil.

My Advice to the Farmer is, that he always examine the Earth in his Paſturage; and that he never fear to take an upland Paſture Ground, if this be the Soil; though it appear but in bad Heart: for he may be ſure there is what is right at Bottom, and he may improve it at Pleaſure.

In this, as all other Inſtances, I adviſe him not to ſpare Manure or Labour. The Money that is ſaved that Way is loſt ten-fold.

The beſt Manure for the upland Paſtures of this Soil, is Dung mixed with Mud from the Bottoms of Rivers, or the Cleanings of Ditches. He ſhould lay on this at ſuch a Time, that the Rain will waſh its Richneſs in before the Sun evaporate it: and he cannot ſpread it too fine in ſuch a Seaſon.

The fineſt Manure of all for this Ground, when it can be had, is the Bottom of old Hay-ſtacks. There is always there a fine rich Mould; and the Quantity of Hay-ſeed among it is no ſmall Advantage; for it ſows the Ground afreſh, and comes up with all the Strength of the Manure.

In STAFFORDSHIRE, where the low Paſtures

are often of this Soil, they manure them with Marle, and it excellently anſwers their Purpoſe: for even where the Mud brought by the Overflowing of a River, would only lie upon the Surface to be baked by the Sun; the Marle will make its Way into the very Heart of the Soil.

CHAP. XI.

Of yellow clayey Soils for Trees.

THIS is not a Soil in which Trees ſhoot quick, but there is a Soundneſs and Heart in it that gives them a great deal of Strength.

I have obſerved, that the Nature of this Soil approaches very nearly to entire Clay: and it is known by all Experience, that no Tree whatſoever thrives well in entire Clay. This is not the Soil therefore on which Plantations are to be made for the Advantage of the Wood.

There is alſo this Reaſon againſt the Farmer's planting on the yellow clayey Soil, that the Growth of the Tree is ſurprizingly ſlow.

It is a Remark of Mr. Evelyn's, That Trees growing on this Ground, require thrice the Time to come to their Stature: and this Experience confirms; for we ſee Trees keep many Years almoſt of the ſame Bigneſs on this Soil: and as for ſuch as are large, it is hard to know when they were planted.

Neither is this yellow clayey Soil any fitter for the Orchard than the Foreſt. Fruit Trees grow as ill in it as Timber Trees: and it even alters the Quality of the Fruit. It is known by manifold Experience, that Apples of the ſame Kind have a quite different Flavour, when the Trees ſtand in a good light Soil, from what they have in this yellow Clay.

Another great Diſadvantage of the yellow Clay for Fruit Trees is, that the Trees which grow in it are found to be much more liable to be over-run with Moſs, than thoſe on better Soils: and every one who has at all conſider'd the Products of the Orchards, knows how great a Diſadvantage this Foulneſs is to Fruit Trees of all Kinds.

The Farmer therefore who has Land with this Soil on his Hands, knows from this what to expect from them. They will anſwer exceeding well with proper Care, in plowed Fields and Paſture: but he is to remember not to make Orchards or Plantations upon them.

If he ſee large Timber upon the Ground, particularly if it be Oak, he need not fear bargaining upon that Head, if it come within his Deſign; for 'tis more likely to be ſound than on any other. Oaks on this Soil are very tedious, but they are very firm.

This Soil is alſo fit enough for the raiſing Seedling Trees, which are to be tranſplanted to another. For, as they never thrive well when removed from a better Soil to a poorer: ſo they on the contrary ſucceed to Admiration, when they are taken from a Soil of this Kind into good Mould.

Thus we ſee from repeated Experience, that altho' the red and the yellow Clay agree in many Reſpects; yet there are ſeveral others in which they are entirely different.' And this is the Uſe of collecting Obſervations from different Places and Perſons.

Although theſe two Soils are ſo like in many Reſpects, the two which follow, namely, the black and the white Clay differ from them almoſt in all. So that he who talks of a clayey Soil, unleſs he expreſſes the Colour, ſays nothing. In general, however, when that Expreſſion, a clayey Soil is uſed without any farther Particulars, it means a red or a yellow.

CHAP. XII.

Of the white clayey Soil.

EVELYN obſerves, that among Clays ſome are ſo obſtinate, that nothing will ſubdue, and others ſo voracious, that nothing will ſatiate them Of the firſt Kind are the two former, the red and yellow; of the other, the two ſucceeding, the white and black, but principally the white; the black in ſome Places approaching to the Nature of the others.

Now as I have ſhewn in what Manner the moſt ſtubborn of the former Kinds, may be ſubdued either for Tillage or Paſture: I ſhall here from the ſame Foundation of Experience, inſtruct the Farmer how he may ſatiate and fill theſe others, whoſe hungry Nature has ſeemed to many not to be conquer'd.

It has been affirmed by ſome practical Writers who have examined theſe Things nicely, that Clay contains about a fourth Part of fine Sand. Houghton, among others, has affirmed this, and brought the Proof of it from his own Experiments. But 'tis only of the red and yellow Clays this ſhould be affirmed. The white Clay contains none: nor would be difficult to produce the yellow Clay altogether pure from it. Indeed there always is ſome in the red, and this is a Reaſon why the red clayey Soil is not quite ſo ſtubborn as the yellow.

It is ſtrange, that among Soils of the ſame Name, contrary Methods are to be uſed in the Culture; but this is the Caſe between the red and yellow clayey Soils, and the white: it is to be obſerved, however, as before hinted, that theſe really agree in nothing but the Name of Clay, their Qualities being altogether different.

The Farmer is to obſerve an exact contrary Conduct with the white clayey Soil, from that proper for thoſe before-mention'd; for his Aim is to be juſt oppoſite: his Care with the others is to make them fine enough: but when he has a white clayey Soil to manage, he muſt take Care he does not make it too fine.

As the red and yellow clayey Soils are tough and ſtiff; the white is tender and brittle: it breaks as it falls from the Plow: and from its Nature in this Reſpect, it yields to the Plow with great Eaſe.

Frequent Plowings were order'd for the others, but a few do for this. As no Soil requires ſo much Care in the Manures, the Farmer's Attention is to be employed almoſt entirely on that Head. In general, as the yellow and red clayey Soils

Soils require ſtrong, this white one requires rich Dreſſings.

In the firſt Place the fineſt Manure for it is Soot. This they practiſe in Hertfordshire, where they have much of this Land, with great Succeſs: and had Mr. Evelyn, who ſays nothing will ſatiate theſe voracious Clays, ſeen the Effect of this Manure, he would have alter'd the Expreſſion.

Soot may ſeem at firſt Sight a dear Manure; but a little of it goes a great way. Experience ſhews that one Buſhel of Soot is equal in its Effects to a Load of common Dung.

Eighteen Buſhels of good Soot will compleatly dreſs an Acre of the white clayey Land; and the ſame Quantity of Ground, as is very well known, will take as many Cart Loads or more of good Dung. But let the Farmer take Care he is not impoſed upon in this London Commodity: For the Chimney Sweepers are apt to mix Aſhes among their Soot to encreaſe the Quantity; and then it may require five and twenty Buſhels to an Acre.

The only way is to deal with reputable Perſons: and, to ſpeak from Experience, I have found Mr. Fat of Caſtle-ſtreet, who is the King's Sweeper, one that never impoſed upon the Farmer; nor let his Servants impoſe upon him.

After Soot, the next Manure for this Soil is Dung. And in this Reſpect, the Farmer will find that the Practice of folding upon it is excellent. Ellis recommends the folding firſt; and afterwards ſpreading it all over with the Dung: and this is found to be of great Service.

Turf and Dung alſo ſuit excellently well with this white clayey Soil: but they ſhould lie to be mellow'd together for a great while.

The white clayey Soil when dreſs'd in this Manner, never fails to yield very large Crops. I have very ſeldom known the Price of Manure not anſwer when it has been of a proper Kind; but there is none that brings home the Money ſo ſure, as that which is beſtow'd on a Soil of this Kind: for it is but indifferent Land in its own Nature, but with this Culture it ſcarce yields to any.

This is not a common, nor a profitable Paſture Soil, nor for the Growth of Trees. I ſhall not, therefore, treat of it in diſtinct Chapters under thoſe Heads; but proceed to the next and laſt of the Clay Kinds.

CHAP. XIII.

Of the black clayey Soil.

HAVING conſider'd the red, yellow and white clayey Soils, I come now to the black, which is the richeſt of them all.

The other Kinds may be brought to Fertility by Art, and with Experience, but this enjoys from Nature the ſame Advantages. The Mixture in this Soil is ſo happy, that it is in its own native State, much like what they are when improved by Culture. Yet even this is capable of great Improvement, inſomuch that it will yield twice the Produce in the Hands of the ſkilful and induſtrious, that it does to the inconſiderate or ignorant.

This black clayey Soil conſiſts like the others of a blackiſh Clay, which is mix'd with a Quantity of vegetable Mould; and alſo contains Sand, ſometimes in a very large, uſually in a moderate Quantity.

The Clay in the Compoſition of this, is not ſo tough as that of the red or yellow, as appears when they are examin'd ſingly; nor yet is it ſo ſhort and crumbly as the white. Thus its own Nature tends to its making a better Soil than either; and then the Sand which it contains anſwers the Purpoſe of that which in other Caſes is to be added; and the Quantity of vegetable Mould gives it great Fertility.

Such is the Compoſition of this excellent Soil; which is in reſpect to its Structure and Conſiſtence, of a middle Nature between the white clayey Soil, and the yellow or red; and exceeds them both in Fruitfulneſs.

This Soil therefore does not require thoſe painful or repeated Plowings, nor that Expence and Tediouſneſs of Manure which are neceſſary to the others: but light Turnings and rich Manures applied in ſmall Quantities, anſwer the Purpoſe. Theſe muſt be uſed according to Knowledge, and as there is no Land ſo well worth the ſtudying as this, there is none that will ſo well reward the Pains.

The Varieties of this Land are called in different Parts of England by different Names. In Hertfordshire, where they are more careful about the Culture of their Land than the naming it, they are all called by one Term black Clay; and the ſame Methods are taken with them.

In Huntingtonshire they have three Kinds of them, to which they give different Names; they call one White Land, another Black Land, and the third Wood Land.

One would think by the Name White Land, this Kind belong'd to another Place: but, in Reality, it has little Title to the Name, it is very nearly allied to their Black Land. When wet, this looks as dark as that does; and when dry, the black itſelf becomes greyiſh. The greateſt Difference in Colour is when both are thoroughly wet, and new turn'd up with the Plow. What they call White Land appears then greyiſh; and the other very dark: but they differ more eſſentially in their Natures.

The Black Land is more clayey than the other, and conſequently requires more Manure; and is much inferior to the black clayey Soil in other Counties. It ſticks to the Plow when plow'd in a wet Seaſon, and has all the Marks of a clayey Soil. They manure this with Marle; and where that is not to be had with Chalk.

This may be an Inſtruction to the Farmer, to diſtinguiſh one clayey Soil of a blackiſh Hue from another; and to treat the worſe Kind properly when he meets with it.

The White Land of this and the neighbouring Counties, for it is common in them, and called by the ſame Name, is truly of the black clayey Kind, it is dark enough when wet, and falls off the Plow-ſhare eaſily, breaking into ſmall

Clods. This is a very rich Land; and is to be treated as the beſt Sort of this Soil.

The Wood Land of this County is nearer the ordinary black clayey Soil of Hertfordshire, and other Places, than any other. I have already named a Soil called Wood Land in ſome Parts of Northamptonshire, which is rather of the Nature of the red clayey Soils: but they have alſo in that County a kind of Wood Land, in particular about Pychely, which is truly of the Nature of the Huntingtonshire Wood Land, and as rich. They have alſo the black and white Lands, and they call them by the ſame Names.

Having thus explain'd what is meant by the different Names under which the black clayey Soil is expreſs'd in different Places, I come to treat of its general Nature, which is ſoft, mellow and crumbly; breaking in the leaſt Froſt.

This Soil is richer in Hertfordshire than in any other Part of England I have ſeen: it is there pure and unmixed. On the contrary in Northamptonshire, it is always ſomewhat ſtoney; but then the Stones are ſmall; and they are of Uſe rather than Detriment, eſpecially where this Soil is not of the firmeſt Kind, for they break and open it, giving Room for the Rains, and for the Shooting of the Seed.

Too much wet is an Enemy to this Land; therefore thoſe Fields which have this Soil, and lie ſomewhat high, are the moſt profitable: but the Generality of it is found in lower Places.

This Soil neither requires ſo much Plowing as the red and yellow Kinds: nor will it do with ſo little as the white. Moderate Plowing is beſt: but when it lies low, I would adviſe the Farmer to plow it with a Foot Plow, only one Way, in broad Lands, laying it in half Acre Pieces as high as may be, for this is the Way to avoid the Hurt that will enſue from its being too wet; as it is very apt to be in theſe low Grounds.

The Farmer who ſhould go to dreſs this Soil like the other clayey Kinds, with Chalk and Sand, and the like, would be guilty of a ſtrange Error. Mellow Dung is the proper Manure for this Land; and adds to its natural Richneſs. Cow Dung is not amiſs for it, but the beſt Manure of all is the Dung of Pigeons. Where this is to be had, the Way of uſing it is thus. It is to be ſprinkled over a Barley Field for Inſtance by Hand, as ſoon as the Barley is ſown. In this Caſe the Rains waſh it in, and the Effect of it is ſurpriſing. Nothing can exceed the Crop that follows ſuch Dreſſing on ſuch Land.

The Dung of Poultry is alſo good uſed in the ſame Way; and any rich and mellow Manure.

This black clayey Soil in Paſture Land is very fruitful, and needs leſs dreſſing than any other; the beſt Manure is Dung, that has lain till it is well rotted: this is to be carefully ſpread over the Ground, that the Rain may waſh it in: and for this Purpoſe it ſhould be laid on in a rainy Seaſon.

Trees of many Kinds proſper well in this Soil; and no where better than in Northamptonshire, where not only the Soil itſelf, but the thick Bed of Clay that lies under it, is intermixed with ſmall Stones.

When the Clay at bottom is more pure, it is liable to the Objections of being too cloſe, and holding the wet, which chills the Roots of ſome Trees to their Deſtruction: but when there are theſe Stones among it, they make it in ſome Meaſure looſe, that it lets the Water drain out; and gives Paſſage to the ſmall Roots.

CHAP. XIV.

Of Loamy Soils.

TREATING of the clayey Soils, we have led the practical Farmer thro' a great Variety of Kinds; each of which it was of the greateſt Importance to him to underſtand. There remain yet five other Sorts of Soil to be treated of. But theſe will be comprehended in a ſmaller Compaſs, none of them having that Variety.

Among theſe thoſe of the loamy Claſs naturally follow the Clays, becauſe they in a great Degree partake of the ſame Subſtances, altho' from the Proportions of the Mixture, they differ in their Nature.

We have ſeen that a clayey Soil is no other than Clay mixed with ſome Quantity of vegetable Mould.

Loam is a Mixture of Clay and Sand: the Sand being in a large Proportion.

A loamy Soil therefore, is a Mixture of Clay, Sand, and ſome vegetable Earth: or it is a Loam, ſuch as before deſcribed, with ſome vegetable Earth among it.

We have ſeen that in what are called clayey Soils, there is uſually a little Sand, but this need not make Confuſion. The Character of Loam is, that there is a great deal of Sand mixed with the Clay; and there is alſo in theſe Soils uſually a great Quantity of Earth.

The loamy Soils are more common than any other: they differ in Colour according to the Clays, and the Earths of which they are compos'd; and they differ alſo in Richneſs and Fertility, according to the Quantity of vegetable Earth in the Compoſition. Even pure Loam is not unfit for Uſe, for the Sand opens and breaks the Clay, ſo as to render it fit for Vegetation; as we ſee in thoſe Places where Sand is us'd upon Clay Grounds, by way of Manure; but when a conſiderable Quantity of vegetable Earth is added to this Mixture, it becomes very fit for the Product of Herbage; the Clay ſerving to give it a Body, and keep the other Ingredients from mouldering into Powder.

Loamy Soils are of all others the moſt natural, becauſe theſe Mixtures of different Earths together, are what may be expected every where: and they agree with almoſt all Kinds of Growths, becauſe they are of a middle Nature, and in ſome Degree partake of all Soils.

They have for this Reaſon been in general called by ſome natural Soil, and by others mother Earth. As all Plants receive their Nouriſhment from the Earth; according as that Earth is ſuited to them, they thrive more or leſs: now, tho' a loamy Soil will naturally ſupport almoſt any Produce of the Ground, yet all will not thrive alike in it. The Art of the Huſbandman therefore muſt be employ'd by proper Manures, to ſuit

ſuit the loamy Soil in his Hands to that particular Crop he deſires ſhould grow upon it; and this may be done effectually.

We ſee by Experience, that Clay and clayey Grounds keep in the Seed a long Time, and puſh it ſlowly; on the contrary, ſandy Soils make it ſhoot at once, and forward it haſtily. The ſame Seed ſown in Clay and Sand, ſhall be a Month earlier in the ſhoot in the latter than the former. We ſee alſo, that this Backwardneſs of the Soil, and this over-haſtening Quality, are both attended with bad Conſequences: and it follows, that loamy Soils muſt be very valuable as they partake of each, and are in their Compoſition, and alſo in their Effects, of a middle Nature between both.

We ſee that loamy Soils are ſuited to univerſal Uſe, in that all Kind of wild Plants grow in them. There are ſome Plants which grow naturally in Clay, and others which live in ſandy Soils. Now the Plants which are Natives of the Clay, will not live in the Sand; nor will thoſe of the Sand live in Clay: but both will live and thrive in Loam.

From this and many other Obſervations, we ſee that the loamy Soil is univerſal; and that all Sorts of Plants will grow in it. This muſt greatly encourage the Farmer who has it in his Fields, but this is not to lead him to think it will do without his Induſtry. There is Difference between growing and thriving. Things muſt not only live but thrive with the Farmer, and to this Purpoſe he muſt aſſiſt and improve his Land when this is the Soil. 'Tis a Comfort that Nature has laid a Foundation; but the reſt muſt come from his Induſtry.

Loamy Soils have many different Appearances. Some call the under-turf Earth, Loam, let it be of what Nature it will, and then the Variety is endleſs; but without that Miſtake, the Kinds are very numerous.

In Hertfordshire, and the adjoining Counties, they diſtinguiſh theſe Soils into five Kinds. Theſe are Clay Loams, Sandy Loams, Gravelly Loams, Stoney Loams, and Chalkey Loams: what they mean by theſe Terms is as follows.

The Clay Loam is a loamy Soil in which there is an over Proportion of the Clay to the reſt of the Ingredients; for theſe Soils, as ſaid before, are all of a very mixed Kind. The ſandy Loam is a loamy Soil, in which the Sand is in too great a Quantity: the gravelly Loam is a loamy Soil, with ſmall Pebbles among it; and ſo of the other two, the one having Stones, the other chalkey Matter among it.

The Farmer is to conſider each of theſe as a loamy Soil in the general Dreſſing; but he is to alter that a little in each alſo; by adding what is elſewhere deſcribed as uſeful for improving that particular Soil, which is over-proportion'd in the Loam. For Inſtance, if it be a clayey Loam, he is to add to the uſual Dreſſings for loamy Soils, a Quantity of Sand. This will make up the natural Deficiency. And in the like Manner he is to manage the others.

In many Parts of Northamptonshire, particularly about Oundle, they have a Sort of Earth which they call Lamb Earth. This is a loamy Soil, and I believe the Name Lamb Earth is only a fooliſh way of ſpeaking Loam Earth. It is a Loam with a great Quantity of ſtony Matter among it. This would have been called a ſtony Loam in Hertfordshire, as ſhewn already: although it differs in many Reſpects, from all the Earths in that County.

It is hard and whitiſh, and beſide the Bits of Stone that are in it, 'tis full of broken Sea Shells. In ſome Places it is the under-turf Soil, and in others it lies beneath that. When it is uppermoſt, they dreſs it with Dung, and the Mud out of Ditches: where it lies under the Soil, they plow deep to turn it up among that; and breaking by Degrees with the Sun and Rain, it ſerves as an excellent Manure to the reſt.

In Kent they dreſs their clayey Loams with Chalk; and this is found by Experience, to be an excellent Method. I have myſelf examin'd many of the Lands that have been for ſome Years dreſs'd at proper Times in this Manner; and have found that the Chalk in time mellows down into the clayey Matter, ſo as to make in the whole a kind of Marle.

I have ſeen Lands there not only made very fruitful in themſelves by this Practice, but the Soil of them might have been us'd as Manure for others.

We ſee that among the Clays ſome are ſo tough, they will not receive Manure, others ſo hungry, they hardly ever are ſatiated; and Sand which takes it readily, yet lets it go again ſo ſoon, that the Farmer has not the Advantage of his Expence or Labour: but loamy Soils have none of theſe Inconveniencies. In the firſt Place, they are in themſelves fruitful: then they are looſe enough in their Texture to let in Manure; and have Firmneſs enough to keep it.

In ſhort, a loamy Soil, where it is not from its Situation too dry or too wet, is an Eſtate to the intelligent and induſtrious Farmer.

With Reſpect to the Manner of its Dreſſings, he is more to regard the Texture of the Soil, than its Colour. which laſt may be various, while the Subſtance is in a Manner the ſame.

If it be a clayey Loam, that is, a loamy Soil with too much of the Clay, let it be well plow'd, and broke thoroughly: then dreſs it with a Mixture of burnt Turf from a Heath, mixed with Lime and Hog's Dung. This Receipt I obtain'd from a Farmer in Oxfordshire, who kept it as a Secret, and was envy'd by all his Neighbours. In Buckinghamshire they dreſs the ſame Soil with a Mixture of Cow Dung, ſharp Sand, and Aſhes of Fuzzes from the Commons, and I have ſeen it ſucceed well, but not equal to the former Method.

When the loamy Soil is too ſandy, Clay may be us'd as a Manure; and at other Times River Mud mix'd with Dung and rotted Turfs: this alſo I have ſeen practis'd very ſucceſsfully.

When the loamy Soil is in its own Nature well mix'd, and no Ingredient over-bears the reſt, Dung in the common Way of uſing ſerves to refreſh it after it has been exhauſted by Crops: and as the Effect of this is but ſhort, the experienced Farmers plow in Horn-ſhavings bought in London, together with Hoofs and Skins of any Animals. Theſe not only give

great Strength and Heart to the Land, but their Effect is very laſting.

When there is too much Earth in the loamy Soil, the beſt of all Manures is Soot. This laid on in a moderate Quantity, gives that Soil the only Thing it wants, which is Warmth. This Sort of Land receives the Manure kindly, and requires moderate plowing.

When the loamy Soil has Stones in Abundance, whether they be of the Lime Stone or Pebble Kinds. And whether it be called a gravelly or a ſtoney Loam, the vegetable Earth being deficient, good mellow dunging is the Way. In this Caſe, I adviſe the Farmer to bring out all the Dung from his Yard, Horſe Dung, Hog, Cow, and Poultry Dung, and mixing it with Mud from the Bottoms of Rivers or cleanſings of Ditches, make it into a Heap in the Field. When he has a good Hill of this Mixture, let him cover it with freſh cut Turf, and leave it to mellow together.

When he is to ſpread this on the Ground, let him take a fit Seaſon: not lay it on in the midſt of Summer for the Sun or Air to waſte its Strength, but toward Autumn, when the ſucceeding Rains will waſh it into the Ground. Thus will he make a Soil that is but unfruitful in itſelf, very rich; for theſe poor ſtony Loams, tho' barren in their own Nature, receive the Dreſſings kindly, and are thus made very fruitful.

In ſome Parts of Surry, they have a very ſtiff clayey Loam, which they treat as follows. After a Fallow they ſow two Crops; and lay down their Lands with Clover for three Years. At the End of this Time they dung it richly, and then it is fertile for ſeveral Years again.

In Hertfordshire they plow in Clover alone, or with Dung; and ſome ſow and plow in Buck Wheat; both which Methods have their Advantage, but they are not comparable to ſeveral of thoſe before mention'd.

I have treated the more largely of the loamy Soil, becauſe it is the moſt frequent, and is very various in its Kinds. Nothing concerns the Farmer ſo highly, as to underſtand its ſeveral Natures, and the proper Management for each; which I have deliver'd from the Experience of ſeveral Perſons in different Counties, ſelecting from a great Quantity of Obſervations in this Way, what ſeems to be confirmed by the moſt frequent Trials. Loam is thus made to ſuit all Sorts of Crops; and is in its own Nature, very friendly to Graſs and Trees of all Kinds.

CHAP. XV.

Of ſandy Soils.

THERE are ſome Parts of this Kingdom in which the Covering of the Earth is for large Tracts together a bare Sand. Theſe are barren, for not only the Winds diſturb the Surface continually, and prevent the rooting of Plants (except a few ſtubborn Weeds that will grow in dry Sand, as others will on naked Rocks) but Sand alone can afford very little Nouriſhment to them: at the ſame Time that it burns up their Roots.

This Sand where it is thus the uppermoſt Covering of the Earth, muſt be called the Soil in thoſe Places; but this is not what the Farmer is to underſtand in general by a ſandy Soil. When we ſpeak practically, we mean by that Name a Soil in which Sand is predominant, altho' there be ſeveral other Earths in the Mixture. From this great Quantity of Sand, theſe Soils are all looſe and crumbly. This is the great Article of their Diſtinction: for that Soil I have already deſcribed, under the Name of a ſandy Loam, is not called a ſandy but a loamy Soil, becauſe the Clay that is in it, notwithſtanding the great Quantity of Sand, holds it together ſo that it is not crumbly or looſe.

The ſandy Soils are in the ſame Manner as thoſe of other Kinds, diſtinguiſh'd into ſeveral Sorts according to their Colours. The three principal are the red, the yellow, and the white ſandy Soil. There is alſo a brown, but this is leſs regarded, and is very barren. It is moſt common on Heaths, and conſiſts almoſt entirely of Sand alone, the Sand which compoſes it is white, but it gets this brown Caſt from a barren browniſh Mould, which lies under the Heath and Furze Roots.

The other Kinds have their Colours moſtly from the Sand in their Compoſition, the three principal Colours of Sand being red, yellow, and white: but ſometimes the Earths in their Compoſition, prevail in Colour.

Beſide the ſandy Soils called by that Name, there are others known by various Denominations in different Counties. As for Inſtance, what are called red Land, and creachy Land in Northamptonshire, are both ſandy Soils; and ſo is the chiſely Land, of the ſame County, tho' ſome call it a Loam.

To theſe is to be added, what in Buckinghamshire they call the black ſandy Soil, and in Hertfordshire the black Sand. This might have been comprehended under the general Head already mentioned of ſandy Soils, to which the other Ingredients give the Colour; for it is not a black Sand that is the principal Ingredient in this Soil, but the Mould amongſt it gives the black Colour to the whole, though the Sand be whitiſh. I have, however, named this Kind ſeparately, becauſe it is much ſpoken of in ſome Places.

The ſandy Soils in general are of their own Nature barren; but they are capable of great Improvement in the Hands of the judicious Farmer. Any Crop whatſoever will be ſooner burnt up in this than in any other Soil whatever naturally; but with proper Dreſſing it ſupports them very well; this the induſtrious Farmer finds to his joyful Experience.

As theſe Soils are dryer, ſo they are warmer than any other: and very happily for the Huſbandman, they keep their good Qualities after the Dreſſing, though they part with their bad ones. Thus the natural good Quality of ſandy Soils, is to puſh any Crop very forward; but then their natural bad Quality is, that they ſoon after ſuffer it to be burnt up: now after due Dreſſings, they will preſerve their Crop, as already obſerved,

ſerved, as well as other Lands; but at the ſame Time they keep their natural forcing Quality ſo well under all theſe Dreſſings, that the Farmer if he manage well, may have two or three Crops from them in a Year.

Another Advantage of ſandy Soils is this, that of all others they are the leaſt productive of Weeds: and what they have of them are in general of the ſmaller Kinds; and eaſily deſtroyed. We ſee all Soils that are at all fit for Culture, have their Advantages peculiar to themſelves; and there is none of them, but with due Management, will prove advantageous.

It is a further Advantage of this Land, that it works eaſily under the Inſtruments of Huſbandry of all Kinds, and freely receives Dreſſings. The rediſh ſandy Soils generally require moſt Manure, the black leaſt; the other two are in general about an Equality.

No Soils receive Moiſture ſo readily as ſandy ones, but they are the leaſt the better for it of any, becauſe as they eaſily let it in, ſo they freely let it out again. The Rains that fall on clayey Soils, frequently do not penetrate into them; and thoſe that moiſten the ſandy, do not ſtay in them; unleſs there be a firm Layer underneath.

The moſt common Layer under a ſandy Soil, is ſtony or gravelly, and this lets the Water through as faſt as the Sand itſelf; ſo that the Farmer's Truſt muſt be in his Manure, to give a Firmneſs and Body to the Soil, that it may of itſelf retain Moiſture enough for the Service of the Crop.

The creachy Soil in HUNTINGTON and NORTHAMPTONSHIRE, which is one of the blackiſh Kinds, and is full of Pieces of Stone, and Bits of Sea Shells, as before obſerved, is manur'd with Dung well rotted. And to this the moſt expert Farmers add Mud from the Ditches, or they cut good Turfs, and put them to rot among the Dung, and ſpread all together before Rains.

The red Land of the ſame Counties, owes its Colour to a rediſh Sand, of which it is principally compoſed. There is a Mixture of very fine Earth with it, but there are alſo Lumps of concreted Sand, which they call Sand Stones: theſe when they break with the Rains, and Tillage debaſe it, while the Farmer is improving it by his Manure. In ſome Places the vegetable Earth is mixed with the Sand in a moderate Quantity, in ſome others, as about HALSTON, 'tis almoſt entire Sand.

The Farmer in general may learn from the Practice of theſe Counties, how he is to treat ſuch Soils. Where the Soil is pooreſt in this Kind, it is generally deepeſt: and as it works eaſily, they plow it deep, and bury in it old Rags, and the Skins of Animals with their Hoofs, and any other ſuch warm Matter; after this they ſpread their Dung, firſt mixing with it Mud out of the Ditches. Thus they give it Warmth at the Heart, and at the ſame Time a Body and Richneſs nearer the Surface.

When this Land is ſo very ſandy, I ſhould adviſe the Dreſſing it with Clay. This would make it a loamy Soil. We know the Value of thoſe Soils, and we know they conſiſt of Sand, Mould, and Clay. Here are the Sand, and more or leſs Mould ready, there wants only the Clay; which will freely enough incorporate with it, and make it ſufficiently firm.

The chifely Land, as they call it in our midland Counties, altho' ſome account it a loamy, is more truly a ſandy Soil. It breaks as it falls from the Plow; and moulders with the leaſt Froſt: ſo that it has little of a clayey or loamy Nature. In dry Summers alſo it is always a Powder. This is far from one of the worſt of the ſandy Soils. They dreſs it with Dung alone, and it yields excellent Crops.

Upon the whole, I ſhould propoſe a Mixture of Soils for all theſe ſandy Lands. They want Body or Firmneſs; and this may be given them by Clay, or by richer Earths, ſpread over them by way of Manure. This would be following Nature's Courſe, and mixing up Ingredients as ſhe does. This Method might be called making, rather than improving a Soil.

The ſandy Soils in a wet Seaſon, proſper greatly with Wheat, Barley, or Oats: but as this Succeſs depends on the Weather, the Huſbandman who runs the Hazard, unleſs he have very well improved them, muſt take his Chance. The fineſt and beſt taſted Turneps are thoſe which grow on theſe Soils. And they are not only well flavour'd but ſound: Worms and other Inſects which deſtroy them, love a moiſt Earth where they can burrow, and lie at Eaſe: they are burnt up in theſe Soils.

Potatoes are very ſucceſsful in ſandy Soils; and it is well known that none are ſo fit for Carrots: Peaſe, Vetches, and Lentils, alſo thrive in theſe Soils exceedingly. And ſo do the foreign Graſſes, Saintfoin and Lucerne, which are Natives of warmer and drier Countries than ours.

In the great Reſpect of Corn, as before obſerved, the Farmer's Succeſs will altogether depend upon his Induſtry; for, though no Soils ſtand more in need of Improvement, they never fail to return the Expence beſtowed on them tenfold.

For Paſture Grounds, a ſandy Soil ſucceeds in Proportion to the Degree of vegetable Earth that is among it: the poor red Land of ROWELL, and other Places in NORTHAMPTONSHIRE, yields very ſweet Graſs; but not a great deal of it, except in Proportion as it is improved by Manures: but when there is a due Mixture of Earth, and the Farmer adds his Dreſſings of rich Dung, Mud, and the like, none ſucceeds more to his Expectations. I believe ſome of the fineſt Paſtures in the World, are to be ſeen in OXFORDSHIRE, and the Soil is generally a yellow ſandy one, but with a good large Proportion of vegetable Earth; and the Farmers keep it warm by frequent Dreſſings.

In WORCESTERSHIRE they have this Soil frequent in Paſture Grounds, and on opening the Earth, there is found to be a Layer of Gravel underneath. They have ſweet and fine Graſs here, and it grows moderately full; but in dry Seaſons it burns up: however, it quickly recovers itſelf on the leaſt Rain. They dreſs it here with Dung in a coarſe Way: if they were more careful in that Reſpect, they would have a much larger Produce.

In

In Lancashire they have a ſandy Soil of a particular Kind; they call it Foxglove Earth. It is a tender brown Soil, full of a ſharp Sand, and with little other Mixture than a fine vegetable Mould. This affords them very good Paſtures. In general the Graſs is ſweeteſt that grows on theſe Soils.

With reſpect of Trees, the ſandy Soil is not greatly to be prais'd for the larger Growths. The Beech ſucceeds beſt in it. And the Hazel, the Holly, and ſome others of the Shrub Claſs, will hardly thrive in any other; for the reſt it wants Body. There is neither Firmneſs in it to give good Hold to their Roots, Richneſs to ſupply them with Nouriſhment, nor Cloſeneſs to hold Water. It may be proper enough to raiſe Seedlings which are to be tranſplanted to richer Soils; but otherwiſe it is of little Uſe in that Way.

CHAP. XVI.

Of gravelly and ſtony Soils.

IN this, as in the foregoing Chapters, it is neceſſary to premiſe, that there is a great Difference between what is called a gravelly Soil, and a Bed of Gravel.

Gravel is very frequent at ſmall Depths in the Earth, and ſometimes it is ſeen in the ſame Manner at the Surface: that is, naked, and without any Mixture of Earth. What is called Gravel, is a Cluſter or Quantity of Flints and Pebbles. Theſe, when they happen to make the upper Surface of the Earth, lie in the Place of a Soil, tho' they cannot be called a Soil properly. They can afford no Nouriſhment for Plants, nor do any grow wild among them, except upon the Sea Shore ſome few that have Roots ſo long they penetrate into the Ground underneath, thro' a Foot or two Depth of theſe looſe Stones.

Such a Covering of the Earth therefore, compos'd of Numbers of Flints and Pebbles alone, is Gravel: but, as in the former Caſes, a gravelly Soil is a Compoſition of Mould, Sand, Clay, or ſome other Subſtance with this Gravel.

The Soil thus compos'd, is diſtinguiſh'd into ſeveral Kinds, according to the Nature of the Earthy, or other Matter that is mixed with it; and hence the Farmers name theſe different Kinds, clayey Gravels, loamy Gravels, or ſandy Gravels: they might add another Sort to be called marly Gravels; for I have obſerv'd in Huntingtonshire, a Soil compoſed of a ſandy Marle and Gravel, with no other Admixture. This turn'd to little Account in the Hand of the Farmer who rented the Land, for he did not know how to dreſs it. The Rains waſh'd down the Marle to the Bottom of the Bed, within a few Weeks after every Plowing, and the Gravel remain'd in a Manner naked; but I am convinced had he dreſs'd this Land with a clayey Loam by way of Manure, it would have given it a Body: the Marle would have blended with the Dreſſing; and they would together have made a Bed capable to hold the Pebbles. Thus a new Kind of Soil would have been made, not unlike what they call a ſtony Loam in ſome Counties, which I have ſeen very fruitful.

I give this Advice to the Farmer, who ſhall have a gravelly Soil of this Kind upon his Hands, from Reaſon and Opinion, not from Experience, or any Thing I have ſeen; but I do not queſtion it would prove ſucceſsful.

As theſe Soils conſiſt of Gravel and earthy Matter, they are in general better or worſe, as that earthy Part is in a greater or leſſer Proportion. There is ſomething in the Kind of Earth, but the Gravel is in itſelf ſo entirely barren, that the great Article of Difference lies in the Proportion.

When gravelly Soils are very poor, it is almoſt vain to try to improve them. When they have any tolerable Mixture of Mould, it will help to detain the Manure, be it what it will; but when there is very little, the Dreſſings be what they will, waſh through them. The Farmers are in many Places ſo ſenſible of this, that they let ſuch Lands lie idle.

In ſome Places the Gravel in theſe Soils, conſiſts wholly of ſmooth round Pebbles, and in others there is a Mixture of irregular Srones among them. In many Places alſo, there are Lands in which the Soil is compos'd altogether of theſe irregular Stones and Mould, without a ſingle Pebble or Flint among them. Through Careleſſneſs this is called alſo a gravelly Soil, tho' it ought to be called a ſtony Soil, theſe ſtony Lumps being broken Pieces of Lime Stone, or other rocky Stones.

This is a much better Soil than the other, becauſe there is a Warmth in the Nature of Lime Stone; and becauſe being of an uneven Shape, they mix better with the Mould, and remain more firmly in it than the Pebbles, whoſe Roundneſs and Smoothneſs makes them liable to fall out continually.

The Soil called in Bedfordshire, and the neighbouring Counties, kealy Land, is of this Kind; and it is tolerably fertile. Barley ſucceeds very well upon it. They manure it with common Dung, and it receives and retains that Dreſſing very well, always keeping its Condition tho' very full of Stones.

The clayey Gravels are a tough and diſagreeable Soil. The Pebbles break the Subſtance of the Clay, and give way for the Rains to come in, and for the Roots of Plants to penetrate, but there wants a Mixture of Earth for the Foundation and Support of the Growth.

Theſe are beſt manur'd with Marle, but a right Kind is to be choſen. It muſt be the light brittle Marle that moulders to Powder in Water. The larger Stones ſhould be pick'd off theſe Lands, and this Dreſſing repeated at convenient Times, and with this Aſſiſtance few Soils exceed it in Fertility.

Loamy Gravels are in their Nature preferable greatly to the former; they are a Mixture of Clay, Sand, fine Earth, and Pebbles: the larger Stones are to be pick'd off from theſe, and the Land is to be dreſs'd in the ſame Manner as the poorer Sort of loamy Soils, as has been ſhewn already.

The ſandy Gravels when they are beſt, are but very indifferent Soils, that is, when there

is the greateſt Proportion of the fine Earth mixed with the Sand and the Pebbles; but when they are poor in their Kind, they are hardly worth cultivating, for the Rain waſhes the Sand down among the Pebbles, and the Manure with it; and the Soil gets into the Condition of a native and naked Gravel, ſuch as has been before mention'd.

If the Farmer have ſuch Lands upon his Hands, or chuſe to meddle with it, he muſt propoſe to be at a great deal of Expence, before he can expect any conſiderable Return. The only reaſonable Way of going about an Improvement, is firſt to make a Loam of it, and then to enrich it with Dung and other Materials.

This is the View he muſt have in his Work, and to this Purpoſe he muſt begin by dreſſing it with Clay. This he muſt take Care to incorporate well with the Sand and Pebbles, and when he has made it as it were a different Soil by theſe Means, he muſt dung it well, for now it will hold the Manure; or if Marle can be had, that will be an excellent Dreſſing.

By this Means he will bring it to be fruitful, but this is a Work of Time, and by his Labour, he rather makes a new Soil than improves the former.

In OXFORDSHIRE they have ſandy Gravels with a very ſmall Mixture of Earth, ſo that they hardly ſtand the Effect of heavy Showers, which make them often look at the Top like a bare Gravel.

When the OXFORDSHIRE Farmer undertakes a Piece of Ground of this Kind, if he find it in this naked Condition, and without ſo much as Graſs upon it; the firſt Thing he does, he folds his Sheep upon it in Winter, and ſprinkles it with Hay-ſeed among the Dung. If the folding be not ſufficient, he adds ſome freſh Dung; or old Straw or Thatch: or ſometimes without folding at all, he ſpreads ſome common Dung, or the Bottom of an old Hay-ſtack: in this latter Caſe, he truſts to the Hay-ſeed that is fallen from the Stack, but if it be only Dung, he uſes to ſprinkle Hay-ſeed with it, that there may be Graſs as well as Nouriſhment for it.

They always find that if theſe Sort of Lands have no Sward upon them before they are fallow'd, they will bear a great Quantity of Weeds, but a very ſlender Crop of Corn.

They fallow in Autumn or Winter as the Sward directs them. If it be a Winter following, they never ſtir it again till they plow it up to ſow it with Barley, and Experience ſhews, as I have frequently ſeen, that this Practice does better than finer Tilling. After this they muſt be kept well in Heart with Manure, but if that be done, they yield good Crops. When worn out, they lay them down with Clover or Ray Graſs. In ſome Places they fallow them every other Year, except they ſow Peaſe upon them.

If inſtead of finding this Land bare, the Farmer ſees it full of Weeds, he begins with fallowing it at once, and afterwards proceeds as before.

I don't give theſe as the beſt Methods: but I have ſeen them practis'd with Succeſs. However, I think thoſe before laid down, as they are founded upon better Principles in Reaſon; and confirm'd in the ſame Manner by Tryals, deſerve the greateſt Regard. In ſhort, the Buſineſs with a gravelly Soil, where it is poor, naked, and hungry, is to give it Earth, and take Care afterwards when a Soil is in this Manner made, to improve it by enriching Manure; in the ſame Manner as if Nature had done the reſt.

In BEDFORDSHIRE, where they have ſome clayey Gravels, they dreſs them in a Way different from all thoſe hitherto named. Their Manure is Chalk, and they blend this well with the Soil by frequent Plowing. Experience ſhews this to be no bad Method, and upon a fair Compariſon between the Crops of theſe Lands, and of thoſe of a like Nature dreſs'd with Marle, the Difference appears to be, that the Effect of the Marle is greater at firſt, but that of the Chalk is more laſting. The Farmer therefore who has both theſe Kinds of Dreſſings in his Power, is to be guided in the Choice by his own Circumſtances.

They have an Opinion, that the Effect of Chalk, tho' it laſts ſo long, yet is fatal to the Land in the End; but this is a Miſtake. It is owing either to their not ſeeing far enough before them; or to their Ignorance of a proper Management at the End of the Time.

It is true, that the Strength which Chalk gives to a clayey Gravel, tho' it laſts a great while, does not hold for ever: but is this a wonder! To be ſure, Land dreſs'd any way will wear out at laſt, but when it comes to this, let it be laid down for Clover or Ray Graſs; and proceed as before directed.

The Farmers ſeeing the Effect of Chalk ſo great, think it will hold for ever; and their own Folly is the Cauſe of the Complaint.

In general, the gravelly Soils need leſs plowing than many others. Thoſe of the clayey Kind, demand more than the reſt; the ſandy very little. They are all forward Soils: but in different Degrees according to their Natures: the ſandy Gravel puſhes the Growth as much as any whatſoever. It requires a great deal of Care in Dreſſing; but when that is done, it anſwers very well: it is a light ſweet Soil, and is hurt by much plowing.

The expenſive warm Dreſſings brought from LONDON, ſuch as Horn-ſhavings, Coneyclipings, and the like, lie a great while in theſe Soils, and continue their Efficacy. On the other hand, the folding of Sheep on them takes the quickeſt Effect, but it is the ſooneſt exhauſted. The Farmer who attends to this, will ſee that there is no giving a general Advice on this Head, but that he muſt conſider his own Situation, as well as the Condition of the Soil. One Manure may be proper if he be like to hold the Land a great while, another if his Time be uncertain: for there is no Occaſion that he ſhould be at a great Expence, for his Succeſſor to reap the Profit; as often happens.

Where the Gravel is ſandy and with a little Clay, the beſt Dreſſing of all others is pure ſoft Mud from the cleaning of Ditches: when the Clay is in a greater Proportion, Marle is better; and when yet more then Chalk is to be uſed as ſaid before. Let not any one ſay I here repeat

what is ſaid before. The Circumſtances vary by ſmall Degrees. I would give the practical Farmer Advice in all: and I had rather be ſuperfluous than deficient.

In fine, the Fruitfulneſs of a gravelly Soil of any of theſe Kinds when rightly manag'd, is ſurprizing. Few Lands produce better Crops of Wheat, and it is a ſtrange Sight to ſee the Corn growing ſo thick, where there ſeems to be nothing but Pebbles: but the Caſe is this, there is Earth at a little Depth, and the Roots of the Corn are fix'd in it although their Stalks ſtand up only among the Stones. When a Soil of this Kind is perfectly manag'd, the Manure proper, and laid on in a right Manner, and at a proper Seaſon, the Rains waſh in all its Richneſs, and the Roots have it: in the mean Time that the Gravel which ſeems naked above, defends thoſe Roots from being burnt by the Sun, and keeps a continual Moiſture, in ſome Degree like what is ſeen under a Stone or Board that lies on the Ground; which feeds the Stalk and Ear every Moment.

The ſtony and gravelly Soils have an Advantage in this Reſpect, over all others; which the Farmer never fails to find, when he brings them in other Reſpects to a level with the others by his Dreſſings.

The gravelly Soils in general, produce a ſweet Graſs in Paſture Grounds, and when dreſs'd according to their ſeveral Kinds, with Mud, Dung, or Marle, they will yield it in a fair Quantity: but the Farmer is to take Notice of this, that there is no Soil for Paſturage that requires more Care than this does, otherwiſe, however good at Heart, it may deceive his Expectations.

For the Manure of Paſture Grounds on a gravelly Soil, there is nothing like a Mixture of mellow Dung, pure Ditch Mud that has little or no Sand in it, and the Bottoms of old Hayſtacks. This ſpread at a Seaſon when there is a Proſpect of Rains to waſh it gradually in, has a prodigious Effect.

Trees ſucceed in this Soil rather in Proportion to what is underneath it, than to the Soil itſelf. The Beech often grows well in it, and the Aſh. In ſome Places the Elm; but not univerſally. The Farmer may obſerve, however, that he need never be afraid of Trees in theſe light Soils hurting his Corn; for they ſeek their Nouriſhment at a greater Depth.

CHAP. XVII.

Of chalkey Soils.

AS there are naked Sand, and naked Gravel in ſome Places, on the Surface of the Earth; in the ſame Manner there is frequently naked and almoſt pure Chalk: and there ar Parts of England in which the Farmers are at the Expence of cultivating it; the Rent being low. But this is not what we mean in general by a chalkey Soil. We expreſs by that Name a Soil in which Chalk is a principal Ingredient; but where, as in the other Inſtances, there are other earthy Subſtances mix'd with it.

A chalkey Soil diſcovers itſelf to the Eye: none more plainly: its Whiteneſs cannot be miſtaken. There are white clayey Soils, as has been obſerv'd before, but they look darker for Rain; whereas the chalkey Lands appear the whiter. There is alſo a Greaſineſs in the Look of the Clays of this Colour, which diſtinguiſhes them from the others.

The chalkey Soils differ more in their ſeveral Kinds than any of the others. In thoſe all the Difference ariſes from the Matter which is mix'd with the main Ingredient; but in theſe that principal Subſtance differs greatly itſelf in various Places. For Inſtance, Gravel is Gravel, and Sand is Sand, whatever is mix'd with them: nor is there much Difference between the Gravel of this Place, and the Gravel of another; but Chalk varies greatly in its Nature and Qualities. There is ſome as hard as a Stone, and others as ſoft as Marle. Yet we call all theſe by the ſame Name, Chalk.

In other Words, there is Chalk to be met with in England, from the Hardneſs of a good firm Stone, ſuch as requires a ſmart Blow of a Hammer to break it, down to the Softneſs of Marle, that may be crumbled to Pieces in ones Hands: now, as the chalkey Soils in ſome Places may have one of the hard or ſtony Chalks for their Foundation; and in others, may be compos'd principally of the ſoft Kind: this makes a great Difference in their Nature, and in the Management they require, independently of the ſeveral other Matters in the Mixture.

It is neceſſary to name theſe Differences in thoſe Soils which go by the ſame Name, to the Farmer, and it will be neceſſary for him to regard them nicely; otherwiſe all Inſtruction will anſwer no Purpoſe to him. One chalkey Soil may be little improved by that Method, which in the greateſt Degree enriches another; and he will learn nothing from all the Experiences of others on this Head, if he do not exactly underſtand on which of the Kinds of Soil compriz'd under this extenſive Term, each was ſeverally employed.

In general, according as the Chalk is harder in theſe Lands, the Soil is the worſe: and it is better as a ſofter Chalk is in the Compoſition.

The ſofteſt Kind of Chalk, which, as I have ſaid, may be rub'd to Pieces in one's Hands, is frequently in theſe Soils, mixt with a fatty and ſomewhat tough Subſtance, which converts it into a kind of marley Earth. This is really a Mixture of a greyiſh Clay and Chalk, and this is naturally the richeſt of all the chalkey Soils. It is alſo the eaſieſt work'd.

A few Plowings do on this Kind of chalkey Soil; and a little Manure. They have it on the Sides of Hills in many Places in Bedfordshire, and the adjoining Counties. They dreſs it at a ſmall Expence, and it produces great Crops.

When the chalkey Soil is of this ſoft Kind, it is to be plow'd deep, tho' not often: on the contrary, the harder chalkey Soils are to be plow'd but ſhallow.

It is a great Advantage of Chalkey Soils, that they are the leaſt of any over-run with Weeds. What they principally produce are Poppies, May Weed, and a few other of the ſlight rooted

and annual Kinds. The pooreſt Kinds are eaſily got into Order; and what is ſpent in Manure, is in a great Meaſure ſav'd in Labour.

In OXFORDSHIRE they are fond of throwing this Land up in Ridges; and in this they are right. The Farmer of another County laughs at them, ſuppoſing they do it for Dryneſs, which is not needful; but their Forefathers who invented the Practice did it for Warmth: and their Deſcendants who follow the ſame Courſe find the Advantages, though they don't know the Reaſon.

When it is of the harder Kind, they dreſs it with half rotten Dung; and when of the ſofter Sort, they lay on fine Mud, and a little well rotted mellow Dung with it. This melts into the Soil with the Rains, and gives it a ſurprizing Fertility.

What they call in many Counties a malmy, or maumy Soil, is one of theſe chalkey Lands: it is compos'd of a ſoft Chalk, and a white Clay together, with a little ſharp Sand. This Mixture naturally makes it ſoft and tender: for the white Clay is not tough in the Manner of the others, as has been ſhewn already, and the Sand makes it more brittle. It falls to Pieces in plowing, ſo that it needs but little of that Exerciſe: and it crumbles with the leaſt Froſt.

This Soil is by Nature in the Condition that many other of the chalkey ones are brought to by Manure and Dreſſing: and the Farmer ſeeing the natural Fruitfulneſs of this, will know he cannot do better with many of his leaner chalkey Soils, than bring them as near as he can to the Condition of this: adding by Art what they want in Nature.

This ſoft chalkey Soil is to be laid in Ridges for Dryneſs, and for Warmth. It requires leſs Manure than many others. And the beſt is rotten Dung.

The lighter and looſer a chalkey Soil is, the leſs plowing it requires: and if the Farmer wants to give it more than needful, ſuppoſing it will ſtill do good, he is to be informed, that he will ſpoil it. Too much plowing in theſe Soils is as miſchievous as too little in the clayey. If theſe be broke too fine, they will not have a ſufficient Body to ſupport the Roots of the Corn, but it will fall down before the leaſt Wind, and be deſtroyed.

For chalkey Soils in general no kind of Dreſſing is ſo good as that which is given by folding Sheep upon them: for this is a Manure that quickly gets into Land: and this light Soil the moſt readily of all receives it; and yet it has Body enough to detain, and take Advantage of all its Richneſs.

There is alſo another Advantage in this Practice, which is, that the continual treading of the Sheep preſs the Ground, and give it a Firmneſs which all theſe Soils want, from the Nature of their Compoſitiun.

In OXFORDSHIRE they plow in old Rags, by Way of Manure, upon the poorer of their chalkey Soils, and that with great Succeſs.

When the chalkey Soil has a Mixture of a tough Clay, as is often the Caſe, it becomes one of the moſt binding Earths the Farmer has to do with. The Manure for this Land is well rotted Dung, with Pit Sand among it: this gives it a Shortneſs with the Richneſs, and makes it work eaſy, and bear well.

In HERTFORDSHIRE the Advantage of Soot is ſo well known as a Manure, that there are few Soils on which they do not uſe it. They find it a very rich Dreſſing for the pooreſt of their chalkey Soils.

They alſo uſe here the OXFORDSHIRE Manure of old Rags; but they lay them on differently. They don't plow them in as in that County; but firſt chop them to Pieces, and then ſprinkle them on by Hand. The Rains ſoon rot them, and carry in their very Subſtance to the Soil, where it proves a rich Manure. Twenty Buſhels of Soot will go as far as Five Hundred Weight of Rags; the Effect of the Soot is quicker, but that of the Rags is more laſting.

The beſt Crops on the chalkey Soils when well manur'd, are Wheat and Barley. In OXFORDSHIRE they make this conſtant Difference betwen the clayey and the chalkey Soil: that on the firſt they ſow Beans after the Wheat, and on the latter, Peaſe; which ſeldom fail of yielding a great Growth.

The Farmer ought to keep a conſtant Regard to the Weather, when he is about to ſow his chalkey Soils. It is of great Importance to him to ſow in a fair and ſettled Seaſon: for any Quantity of Rain falling ſoon after the Sowing, will bind ſome of theſe Soils ſo hard, that the Seed will be loſt.

Oats do very well upon theſe Soils, but not like Wheat or Barley; and of the two laſt the Wheat is the moſt to be depended upon. The Barley that has grown upon chalkey Lands, is preferr'd by the Maiſter to that of any other Soil whatſoever; but this is a Crop that does not make ſuch certain Returns, the Farmer that chuſes it muſt ſtand the Hazard; for ſometimes it fails ſtrangely.

Rye alſo ſucceeds on a chalkey Soil properly dreſs'd: no where better.

It is not only Peaſe that grow ſo freely upon theſe Soils; they agree in a particular Manner with all the Pulſe Kinds. Tares and Lentils will grow well upon the very pooreſt of theſe Chalks.

No Soil better nouriſhes the tenderer of the Graſſes; Clover does not do well except upon the richer Kinds; but in general, the Saintfoin, and the other fine Graſſes, ſucceed upon them to Admiration, becauſe of the Lightneſs; particularly the Saintfoin, whoſe long Root pierces to a great Depth, and will therefore find Moiſture and Nouriſhment, when all is dry and parch'd on the Surface.

Chalkey Soils are not the moſt favourable for large Growths of common Graſs for Hay; but they furniſh a ſweet Kind for Paſturage; and the better Sorts of them when dreſs'd properly with Mud and rich Dung, will afford very fair and tall Graſs. But it is a Soil naturally found in hilly Places, and that ſeems deſtin'd by Nature for the Plow: rather than for the Growth of Trees or Graſs.

CHAP.

CHAP. XVIII.

Of mellow Earth.

WE come in the laſt Place to the Conſideration of that Soil which is called Mould, or mellow Earth; the Richeſt in its own Nature of all; and needing leſs Dreſſings than any other; yet not entirely above the Neceſſity.

As the Soils laſt treated of, the chalkey Kinds, are naturally met with on Hills; the Seat of this is in the Valleys and low Grounds; and as thoſe ſeem deſtin'd by Nature for the Plow, theſe are in the ſame Manner for Paſture.

This is its Condition in its moſt pure and entire State; but there are ſeveral Kinds of this Soil, as well as of the other, although they have hitherto been leſs taken Notice of, and ſome of theſe are found on higher Situations, and admit the Plow; and yield large Crops of Corn.

What is properly called Mould, is found in in its moſt pure State under the Turf in Fenny Countries. Here there is neither Clay, Stone, nor even Sand amongſt it. In other Places it is mixed in a greater or leſſer Degree with one or other of theſe.

Properly ſpeaking it is to be called Mould only, in this State, as Gravel, Chalk, Clay, and the reſt are only called by thoſe Names ſimply when they are pure: and as they when mix'd with other Ingredients make the gravelly and other Soils named from them; ſo when this Mould is found mixed with Clay, Sand, or the like, it conſtitutes many of the ordinary Kinds of Soil. But theſe are not called mouldy Soils, but mellow Earths. So Cuſtom has eſtabliſhed.

It is only, however, when the Mould is in the greateſt Quantity, that theſe Mixtures have the Name of mellow Earths: when the Sand is in the greateſt Quantity, the Soil is called ſandy; when Clay, it is called a clayey Soil. For the Mixture of Mould when ſmall, does not give a Name to the Soils; but, as before obſerv'd, converts the naked Gravel, or pure Clay, or the reſt into a Soil.

I have ſpoken all along of a pure vegetable Earth being mixed with theſe ſeveral Ingredients in the Formation of Soils. This Mould which is the Foundation of the mellow Earths, is that vegetable Earth. I have ſaid at firſt that it is ſcarce ever found entirely pure: but there are Places were it ſufficiently near Purity, to give a full Knowledge of its Nature.

The Gardeners frequently deſire to have the vegetable Earth pure; and on this Occaſion they ſeek for it in old Willows, and other decay'd Trees. What they find in theſe Places they call Virgin Earth, and pure Earth. It comes the neareſt what we mean by pure vegetable Earth: and we meet with this Mould in ſome of the Fenny Countries very like it in all Reſpects.

In Lincolnshire their fine Fen Land is of this Soil. A fine black Mould lies under the Turf in a Bed of very conſiderable Thickneſs It is light, looſe, and black, and one ſcarce perceives any other Mixture in it but a little Sand, and that indeed is very little. It is ſpungy when wet, and when dry it eaſily moulders to Powder, and the ſmall Quantity of Sand lies naked among the reſt.

Some imagine Turf or Peat to be the natural Surface of all the Fen Lands, but that is owing to their Unacquaintance with the Matter. The right Turf or Peat is compoſed of decay'd Stalks of Plants, and other vegetable Subſtances, with a bituminous Matter that holds them together: it lies at ſome little Depth; and this fine black Mould in the rich fenny Lands lies over it, and immediately under the Sward.

There is no Soil in the World ſo fertile, or ſo rich, as this Kind of Fen Land, and it is owing to the Excellence and Purity of this Soil, which conſiſts of ſcarce any Thing but vegetable Earth. Too much wet affects it greatly: and as it lies uſually in theſe low Places, it is very ſubject to this Inconvenience; otherwiſe it would be preferable to all other Soils in the Eye of the Farmer.

In the fenny Countries, where this Soil is frequent, they call it moory Land; and they value it very highly when it can be tolerably preſerved from wet.

This is the pure and perfect Soil of the Fens when they are not any way ſpoil'd. But beſide this, there is another mellow Earth in the ſame Situations, which they call Fen Land; this is a Name they give alſo in ſome Places to the laſt deſcribed; but, as they uſe it in ſome Places for the other, as diſtinguiſhed from that by its Compoſition, and as it has no other Name, we muſt be content to call it by this to avoid Confuſion.

This Fen Land is a mellow Earth compoſed of the fine black Mould juſt mention'd, and a tough blackiſh blue Clay. It is black and ſoft: and has at a Diſtance very much the Appearance of the other. This is next to the moory Land, the richeſt Soil that is known for Paſturage. It needs little Manure, and in moſt Places Nature takes Care of that Article. It generally lies in the Reach of being overflow'd by the Rivers, when ſwelled by Land Floods; and as this Water ſtands upon the Lands ſome Time, it leaves a fine rich Mud at its going off, which ſerves in the Place of Manure: and is better ſpread and let into the Ground by the Water wherein it is brought, than it could be by all the Farmer's Toil and Ingenuity.

We read of the River Nile in Ægypt overflowing their low Lands, and leaving its Mud, which ſaves the Farmer's Labour, and occaſions the great Fertility of the Soil. The ſame Thing in a leſſer Degree happens in theſe Fen Countries after every Inundation.

The Fen Land when dry, is tolerably firm and hard; and it then looks of a ſomewhat paler Colour: when wet it is blackiſh, and is ſoft and mellow, but with ſome Toughneſs. It has alſo a Smell at this Time like the Mud of a Pond in Summer, when the Sun has newly dried up the Water. This Soil is more apt to be wet than the moory Land, becauſe it has a deep Bed of Clay at the Bottom, and has too much Clay in its own Compoſition to part with Water ſuddenly.

It

It is alſo ſingular, that in the Fen Land there is no Sand. This is an Ingredient almoſt univerſal in other Soils; but in the true Fen Land, there is not a Grain of it to be found.

This Soil, though called Fen Land, becauſe uſually found in the Low Country, ſometimes alſo is met with in the higher Paſtures: but it is never ſo fruitful then as in the low Grounds, though it be evidently the ſame in its Nature and Compoſition.

I have particularly taken Notice of this about the Edges of the Fens, where the ſame Land or Soil that has run under the Turf in a low Meadow, has been continued through an adjoining Paſture which was a little riſing. The Paſture in this Caſe never is ſo rich as the Meadow, and the Reaſon of this is certainly, becauſe the Paſture Ground was out of the Reach of the Land Floods, which, running over the other Ground at times, left the Mud upon it to enrich its Nature.

The practical Farmer may learn by this, what he is to do with a Paſture which lies ſomewhat high, and has this Fen Land Soil. He is to dreſs it with Mud from the Bottoms of Rivers or Ponds, ſpreading it thin before Rain, that it may be waſh'd into the Ground; it is thus Nature enriches theſe Lands by the Overflowings of the neighbouring Rivers, and in this Manner Art may imitate her Proceedings; which are always the beſt Example it can follow.

The Effect of the Mud thus waſh'd into the Fen Land Soil, is to make it more and more like the Moory Soil, which is the richeſt of all others.

I have already mention'd in the general Account of Soils, one which in NORTHAMPTONSHIRE they call Henmould: this is common in the richeſt Paſtures of that and the neighbouring Counties, and is little other than the moory Land taken out of its low Situation. It is blackiſh, light, and fine, and is compos'd of the ſame fine black Mould with the other, only there is more of the Sand in the Compoſition.

We find this Soil principally, and in its greateſt Perfection, in thoſe Paſture Grounds that lie toward the Bottoms of Hills. I ſay in Paſture Grounds, for the Farmers who are acquainted with its Nature, do not chuſe to plow it; for, notwithſtanding its Fertility, it wants a Body to ſupport the Roots of the Corn.

In LANCASHIRE and the adjoining Counties, they have a Soil which they value exceedingly for its Fertility, and which they call the black Soil from its Colour. This is compos'd for the greateſt Part, of the ſame fine black Mould with the moory Land, but it has a larger Proportion of Sand, and ſome Clay among it. To ſpeak exactly, the black Soil of LANCASHIRE is compos'd of the Mould and Loam: according to this Compoſition, it differs both from the Moory Land and the Fen Land. For the firſt of theſe has ſome Sand in it, and no Clay; the other has a great deal of Clay and no Sand. This having both, is of a different Nature.

The black Soil in LANCASHIRE is not only very rich in Meadow and Paſture Ground, but in Corn Lands. The Clay in its Compoſition, is ſufficient to give it a Firmneſs enough to ſupport the Crop; the want of which is the Occaſion that the rich Henmould of the other Counties before mentioned, cannot be us'd for Corn.

In the ſame Part of the Kingdom they have alſo a rich Earth which they call the Foxglove Soil. They are not ſo exact in theſe Names as they ſhould be; but I ſhall always endeavour to explain them as well as I can, my Intention in theſe Things being to make the Farmer of one County underſtand him of another.

In LANCASHIRE they in general give the Name of Foxglove Earth to a fatty Soil of a brown Colour, and tolerably rich, but in ſome Part of that County, and in general throughout CHESHIRE, they call an Earth by that Name, which greatly exceeds the other in Fertility. This rich Foxglove Earth is a mellow Soil compos'd of the fine Mould before nam'd, and a conſiderable Quantity of Loam of a reddiſh Colour. I have obſerved theſe two different Soils in LANCASHIRE, the firſt in the low Grounds, where it makes a Soil altogether the ſame with the moory Land before deſcrib'd, and the other in the Paſtures on the Sides of Hills.

As I have ſeen theſe ſeparate, and traced them to the Mixture, I have found that the fine and rich Foxglove Earth of thoſe Counties, is compos'd of them. This is a very rich Soil for Paſture Grounds: the Graſs is ſweet, and in great Quantity.

I before mention'd alſo, an Earth which in ſome other Counties they call Henmould, and which is different from that which goes by the ſame Name among others: this is alſo of the Nature of the Foxglove Earth, it is a Compoſition of fine black Mould, a good deal of Clay, and a little Sand; or in other Words, it is compos'd of black Mould, and a clayey Loam. The whiteiſh Streaks they find in this on firſt opening it, are no other than the firſt Shootings of Muſhrooms: what Gardeners call the Spawn of Muſhrooms. The Paſture Grounds of this Soil are found to bear great Quanties of theſe; it is therefore no wonder this Spawn, as it is called, is found under the Surface.

This Henmould Soil will bear Corn tho' the other will not: it agrees with the Foxglove Earth in its Nature as well as Appearance: having a ſufficient Quantity of Clay in the Compoſition to hold the Root firm.

Having thus deſcribed the ſeveral Kinds of mellow Earth in ſuch a Manner, that they may be diſtinctly known from one another: it remains to give the Farmer, who ſhall be thus made acquainted with their Nature, the neceſſary Inſtructions in what Manner he is to employ them to Advantage.

In the firſt Place then, he will ſee by what has been ſaid already, that as many other Soils are naturally calculated to bear Corn, theſe are naturally ſuited for Paſture.

They will all produce good Graſs without any Exception: there are one or two of them that may be made to anſwer for Corn; but the Generality of them are not fit for that Uſe, nor ſhould a Soil be forced by the Farmer.

If he happen in any Situation to have an over Proportion of plow'd Land to Paſturage in his Farm, ſo that he cannot raiſe a Supply of Dung from the Cattle of the one, for the needful

Manure for the other. In this Caſe it will be neceſſary for him to lay down ſome Part of his Arable to Paſture; and in the ſame Manner if his Paſture Land be ſo much, that there is more Dung produced by the Cattle than he can uſe on his Fields, it will be prudent in him to convert ſome of his Paſture to Corn Land. For it is always the Farmer's Intereſt, as nearly as he can, to keep up this Proportion.

Now if it happen that his Paſturage be principally upon this mellow Earth; his Buſineſs is firſt to examine if it be of one Kind throughout the whole Farm, or if there be a Variety.

The latter is more uſually the Caſe; and ſuppoſing it ſo in the preſent Inſtance, let him chuſe out the Piece that ſhall be plow'd according to the Account that has been given of their Natures.

The mellow Earths are all ſo rich, that they will ſupply Nouriſhment abundantly to a Crop of Corn; but the greater Part of them are, as has been ſaid, ſo looſe and crumbly, that they will not ſupport the Crop in their Place. They will never ſettle enough to the Roots of the Corn to keep it ſteady whilſt it is growing up, and when it is not firm it can never thrive.

But this is not the only Objection againſt converting this mellow Earth, which is the natural Soil of Paſturage, to Tillage. The finer Kinds of it are apt to be wet, they generally lie over a Bed of heavy Clay; and almoſt always in low Situations. The Conſequence of which is, that though they abound with Nouriſhment, it is of too moiſt a Kind, and feeds the Leaf rather than the Grain.

I have obſerved in Cheshire, when ſome Fields of this Soil that lay at the Bottom of Hills, have been forced into Corn Lands; the Farmer has expected great Profits at firſt, for the Corn grows upon them prodigiouſly, but the Nouriſhment goes to the Stalk and Leaves: it is over rank in the Straw, but lean in the Ear, and to the early Promiſe has ſucceeded a late Diſappointment.

Having ſeen thus much from Experience, I may have Leave to adviſe the Farmer as before, not to be too fond of converting this Soil from Paſture to Arable. But if he be under a Neceſſity of doing it, let him take the following Rules for his Inſtruction.

Let him chuſe out of all the Kinds in his Ground, that which has moſt Clay or Loam in the Compoſition; for that, altho' it ſucceeds by ſo much the leſs in Paſture for this Addition, is the only one fit for Corn; becauſe it is the only Kind of mellow Earth that will cloſe enough about the Roots of the Corn to keep it upright and firm. By obſerving this Rule he will take the Piece that is leaſt valuable for Paſture; and at the ſame Time that which is beſt for the Corn: thus reaping a double Advantage.

In the next Place, let him chuſe ſuch a Piece as lies ſomewhat riſing; becauſe the Abundance of Moiſture is the Cauſe of that Rankneſs in the Stalk, which robs the Ear; and thoſe mellow Soils that lie on the Sides of Hills, are never ſo damp as thoſe at the Bottoms; the Water being continually draining off from the one, and running to the other.

This Rule will naturally fall in with the other: for the mellow Earths on riſing Grounds are always more clayey or loamy than thoſe which lie flat. This is the Conſequence of the Difference of Situation, for the fine Mould is continually waſhing off from the one, and coming down upon the other.

When the Soils of this Kind are forced into the Service of Corn, the beſt Manure for them is rich Dung. It is not eaſy to mend the Texture of a loamy mellow Earth; and therefore all the Farmer is to aim at is, to ſupply the Richneſs of the Soil in Proportion as it is exhauſted by his Crops.

In Leicestershire where they plow ſome of theſe Lands that are a little over clayey, they dreſs them with Marle to good Advantage.

The ſame Sort of Soils I have ſeen in Lancashire dreſs'd with Lime and Soap-makers Aſhes; the Farmers there ſuppoſing it too cold in its Nature, and giving theſe Dreſſings to warm it: this Practice was not without Succeſs; but the other Way with Marle upon equal Terms, I have always found had the Advantage, both in preſent Profit and in laſting.

In Lincolnshire they plow in Hare Skins, Rabbit Skins, and old Rags into theſe Soils when they dreſs them for Corn, as they ſometimes do thoſe that lie on the Sides of Hills.

Woollen Rags are altogether as good as Linnen on this Occaſion. There is a famous Inſtance in Northamptonshire, of a Man's dreſſing a Corn Land on a Soil not unlike one of theſe, with Taylors Shreds ſteep'd in Urine; the Conſequence of which was ſuch a Crop, as ſcarce ever had been ſeen.

This is a well atteſted Fact, all the Country talk of it; and it may ſerve to recommend to the prudent Farmer, a Manure which he may have at a moderate Expence from London, and which is likely to anſwer ſo greatly.

Having thus far conſider'd the Manures that are proper for mellow Earths, when they are uſed for Corn; it remains to recount thoſe which Experience has ſhewn to be moſt uſeful for it in Paſture. I have already ſaid this wants leſs Dreſſing than any other Soil whatſoever; but the beſt in the World may be improved by ſome Manures.

Before the Farmer take any other Step in this Matter, let him carefully examine the particular Kind of the Soil.

If it be a mellow Earth, with a good deal of a loamy Mixture, let him imitate, as before ſaid, the Courſe of Nature in enriching it; and ſpread upon it at proper Times, the Mud from Ditches and Rivers.

If the Soil be a mellow Earth, with an over Proportion of Clay, ſuch as the Fen Land is, where there is no Sand in the Compoſition, it is to be dreſs'd with rotten Dung, mix'd with the Cleanings of the Highways, which are of a ſharp ſandy Nature, and will by Degrees get in and break the too great Firmneſs of the Clay, reducing it to a kind of Loam.

Theſe Soils may alſo be improved, according to their Compoſition and Situation, by Dreſſings; conſiſting of Earths, or Soils of other Kinds. Thus the moory Land of Lincolnshrie might be

be converted as it were, into the black Soil of Lancashire, by dreſſing it with a brittle Loam, as that would mix both Sand and Clay in the Compoſition; and thus it would be made fitter for the Plow, if it be needful to put it to that Uſe.

In the ſame Manner the Henmould of Northamptonshire, and other Counties, might be made more fit to receive and ſuſtain Crops of Corn, by dreſſing it with a clayey Loam, which would break in upon it by degrees; and when well mix'd with the Plow, would give it that Firmneſs it wants.

This is conſidering Manures in a Light in which they are not ſufficiently regarded by the Generality of Farmers. The common Way of dreſſing with Dung, and the like, is enriching, but this is making a Soil.

The richeſt of theſe Soils for Paſture, that is, the moory Land, is liable to great Damage by Wet. The Remedy for this is burning the Land: this is practiſed to great Advantage in all the Fen Countries; and it may be introduced elſewhere to the Farmer's great Profit.

The moory Soil, as it moſt wants this Method of Improvement, ſo it ſucceeds with it the moſt readily of all; burning more freely than any other Land: the Herbage on its Surface kindling eaſily, and burning well.

The Method practiſed in Lincolnshire, where they underſtand this Practice beſt, is this; they plow up the Sod as ſhallow as they can, and pile it up in little Heaps, laying ſome Pieces of Furze Buſhes, or ſome Pieces of Peat Earth here and there among it, to make it burn well. When this is done, they ſpread the Aſhes, which greatly enrich the Land: ſo that it becomes not only drier, but in all Reſpects better than before.

The Trials that have been made of reducing this Paſture Soil to Arable, have ſeldom ſucceeded: after a little Time the Farmers have been glad to lay it down to great Sward again.

If at any Time the Farmer who ſhould try the Experiment, ſhould be brought to the ſame Neceſſity, as is not unlikely, I ſhall give him the Advice that the laſt Crop he ſows upon it be Wheat. Becauſe in that Caſe the Ground will gather Graſs before the Wheat is cut: and the Stubble is of Uſe in manuring the Ground.

But tho' theſe mellow Earths in general do not ſucceed ſo well with Corn, there are other Crops for which they are plow'd to great Profit.

Coleſeed will thrive exceedingly upon the melloweſt of them all. They frequently plow up the moory Land, which is all black Earth, without almoſt any other Ingredient for this Purpoſe, and it yields vaſt Crops.

The principal Manure they uſe for the Lands on which they raiſe this Crop, is the burning of the Sods before mention'd; and they find that Coleſeed always thrives vaſtly better on a freſh Land than any other: but it will ſucceed very well on the ſame Land again; burning the Stubble.

This is the only Uſe the Stubble of the Coleſeed Plant is fit for; they never plow it in, for it is ſo hard and ſticky it will not ſoon rot.

Oats, next to Coleſeed, thrive beſt on the richer Kinds of theſe mellow Earths. As the Coleſeed does beſt on freſh Land, the Farmers in Lincolnshile, when they have had one Crop of Coleſeed, generally ſow Oats the two or three following Years, which anſwer very well with a little Manure. They ſometimes ſow Wheat or Barley after the Coleſeed, but it is not ſo ſure of Succeſs. In a dry Year it is often render'd of no Value, by tumbling down from the looſe Nature of the Soil not holding the Roots; and in a wet Year the Ground becomes ſo damp, that the Growth is rank in the Stalk, as mention'd before, but thin and poor in the Ear.

After three Years Oats, upon a Year of Coleſeed, the Cuſtom is to lay it down for Graſs. For this Purpoſe they ſow Ray Graſs with the laſt Oats; and when it has been kept thus ſix Years, they plow it up ſlightly, and burn the Sod, after which they ſow it with Coleſeed again.

The mellow Earths of the finer Kinds, are not very favourable to the Growth of Trees. One Reaſon of this is, that they want Firmneſs to hold the Roots, for there is Abundance of Nouriſhment; another is the great Moiſture.

In the pureſt Kinds, ſuch as the moory Land, we ſee ſcarce any other Tree except the Willow. This is the Fen Tree, and often in the Compaſs of a great many Miles no other ſhall be ſeen.

As the mellow Earths partake more and more of the Nature of the other Soils, they more reſemble them in their Trees. Thus when this Land gets a ſmall Proportion of Loam, the white Poplar grows freely upon it: and the Foxglove Earth of Cheshire, and ſome of the mellow Earths of Northamptonshire, bear the common Kinds of Trees in ſufficient Perfection.

In general, Trees grow quickeſt in a rich, but they are firmeſt in a ſtrong Soil. The Oak grows tediouſly in the clayey Grounds of Northamptonshire, but its Wood is found in Proportion.

This is not an Obſervation in favour of theſe mellow Soils for Trees: but 'tis proper, ſince the Truth confirms it, to lay it down as a Caution to the practical Farmer, that he make no Attempts of that Kind. Every Soil has its natural Produce: and ſo far as Convenience will allow, that ſhould be followed; for whatſoever is the Growth to which a Soil is fitted by Nature, the ſame is that with which it will beſt ſucceed under the Improvements of Art.

The End of the First Book.

Appendix to the First Book.

Of the Uſes of Clay, Loam, Sand, and other Subſtances found on or in the Earth, in their various Arts; and their Value to the Owner.

The INTRODUCTION.

Of the Deſign and Bounds of this Appendix.

HAVING conſider'd the ſeveral Kinds of Clay, Sand, and the like, as they enter into the Compoſition of the different Soils; it remains that we enquire into their Nature and Uſes in their pure and unmix'd State.

They not unfrequently lie on the Surface of the Earth, or make its uppermoſt Covering in their entire State. It has been obſerved already, that in this Caſe they are not properly called Soils, though they take the Place of a Soil; and that they are frequently in this Condition, not worth the Expence and Labour of Dreſſing.

Although they do not come under the Farmer's Conſideration in this State as Soils; yet making a part of his Land, it is needful he ſhould underſtand their Value, and how to make the moſt of them.

This Examination did not come under the Heads of the preceding Book; the Subject of which was the underſtanding of Soils, and their Improvement for different Growths: to avoid Confuſion, it is therefore treated of in this Appendix by itſelf.

To enquire into the whole Compaſs of the Uſes to be made of Things found under the Surface of the Earth, would be a Subject too wide, and foreign to the Purpoſe of this Work: but ſo much of this Enquiry as may concern the Farmer or the Country Gentleman, ſhall be inſerted.

The Deſign of our Undertaking is to inform the Poſſeſſor or Cultivator of Land, whether Owner or Tenant, of all it can be uſeful to him to know reſpecting it.

The Plan of the Work engages to enquire into theſe occaſional Uſes of Clay, and the other Subſtances; and it would be leaving the Poſſeſſor of Lands in the dark, as to ſome Uſes he might make of them, ſhould any Thing of this Kind be omitted.

The Intent of this Work is to be as largely and as generally uſeful as poſſible.

CHAP. I.

Of the Uſes of Clay.

THE Farmer who finds Clay naked on the Surface of ſome Part of his Land, needs not deſpair of Advantage. Though it may not be worth the Charge of Culture, it may anſwer other Purpoſes: and that he may know what to expect from each Kind, they ſhall ſeverally be recounted.

The firſt Thing to be done is, to enquire of what Kind the Clay is, and of what Nature. Here following the Diviſion before eſtabliſh'd of the four Kinds of Clay according to their Colours; the two firſt, that is, the red and yellow, are the moſt frequently found at or near the Surface: the black and the white Clay in moſt Places lie under the Soil, or at greater Depths.

When theſe are altogether pure at the Surface, he may begin with them there; but when they have ſome Mixture there, as where there is what may be called a very poor red clayey Soil, the red Clay will probably be found quite pure and entire at a little Depth, and that often in ſo thick a Bed, that the opening a ſmall Pit for it, brings great Profit with very little Expence of Labour.

The red Clay is the moſt valuable, as it anſwers not only the beſt Purpoſes, but the greateſt Number of them. It is not of a perfect red Colour, as the Name uſually given it ſeems to expreſs; but brown, with a Tinge or Caſt of rediſh. It has the Name of red by way of Diſtinction from the yellow.

Nothing is equal to pure red Clay for ſecuring the Bottoms of Ponds for holding Water. When the Nature of the Earth is ſo looſe that they drain dry, whether the Soil be gravelly, ſandy, or whatever, if the Bottom be lined with red Clay well rammed, the Pond will hold Water for many Ages, as if it was dug in a Bed of Clay. In ſome Places they improve upon this. They firſt ram down a lining of red Clay, and upon that lay a good pitching of Stones; this makes a Bottom as firm, as ſecure, and as durable as Lead.

The

The red Clay exceeds all others for the Brewery. 'Tis beat and temper'd to a due Conſiſtence for covering Bungholes of Barrels. If the Farmer at any Time finds it apt to crack, the Remedy is to beat it up afreſh with ſtrong Brine inſtead of common Water: this keeps it firm and entire.

In the Grafting of Trees they prefer the red Clay to any other, but they beat it up with Horſe Dung, this prevents it from cracking as it dries: with Hay chop'd ſmall, it makes a Covering for Sheds and Cottages, inſtead of Walls. This anſwers the ſame Purpoſe with Dung in the other Inſtances; and might in others.

When calcin'd, it makes an excellent Manure. This Management reduces it to a Powder like Aſhes. This is to be ſprinkled by hand over the Ground, and is excellent either for Paſture or Corn Lands: it gives Strength and Heart to other Soils. This is a new Practice, and is one of the great Improvements of the modern Huſbandry.

Theſe are the principal Uſes of the red Clay; and from this it is very plain, that a Pit of it open'd in a convenient Place, may be of vaſt Uſe to the Proprietor himſelf, and may afford conſiderable Profit by the Sale.

The yellow Clay is neareſt to the red in its Nature and Qualities, and is uſed in general for the ſame Purpoſes. It is often found as perfectly pure as the red, and is then as ſmooth and fine, but it wants ſomething of that ſound Firmneſs there is in the red Kind. Where the red is to be had, this is to be rejected as inferior; but generally thoſe Counties which produce the red in Abundance, have little of this; and on the other Hand, thoſe where this yellow Clay is common, have not a great deal of the red.

Nature ſeems in theſe Counties to have given the yellow Clay to make Amends for the Want of the red; and it is to be uſed in its Place, but there muſt be more Care in the managing it. Although it ſeems to temper with leſs beating, yet in order to bring it to a good laſting Conſiſtence, it requires more than that; and when all is done, it is more liable to crack as it dries, and to waſte upon the Surface by continual wet: for it ſoon grows ſoft and pappy where wet always lies upon it, though this be only to a little Depth. The other therefore, where the Farmer has his Choice, is to be prefer'd for all Purpoſes.

There are many Things in which the red and yellow Clay agree, as they are nearly of the ſame Nature. Either of them will ſerve for Bricks: the red in particular makes an excellent Kind, of no very bright Colour, but of great Strength. They are not uſed much, however, for theſe Purpoſes: the Brick Makers do not chuſe to make pure Clay; it takes a great deal more Labour and Time to temper it for the Mould; and when it is done, ſhrinks in the drying. The Bricks made of it are ſtrong, but dear.

They prefer for their Uſes ſome of the Loams to be deſcribed in the next Chapter, becauſe they cut and temper eaſier. Where theſe are not to be had, they will uſe Clay, but then they mix it with Aſhes, and the Dirt out of Streets to give it a due Shortneſs, and make it work eaſily.

When the Loams, which they properly call Brick Earth, are not ſandy enough, they mix Aſhes or other dry Stuff with them in the ſame Manner.

Both the red and yellow Clay are uſed alſo in the Potteries of ſeveral of our Manufactures, but ſeldom alone. The yellow is one of the Ingredients of the common STAFFORDSHIRE Ware; and the red is mix'd into the Compoſitions for their better Work. The yellow is alſo a common Ingredient in making of Garden Pots, for it burns to a rediſh Colour.

The beſt natural Clay I ever ſaw for Bricks is in OXFORDSHIRE, where in ſeveral Places I have ſeen a mix'd Kind, partly yellow, partly blueiſh, of a tender Nature, and with ſome Sand among it; this works eaſily, and makes exceeding good Brick.

If the Farmer find an Earth of this Kind, provided it be in the Way of good Carriage, it is a Treaſure; no-body will take the tough Clays for Bricks, if they can get theſe which are tenderer: if they are abſolutely brittle it will not do, but the middle Conſiſtence is what gives them their Value.

It is very common that where the Clay near the Surface, is of a tender and brittle Kind, there is a Bed of a firmer and tougher Sort underneath. It often happens that theſe two being mix'd together, make an Earth of a due Conſiſtence. For theſe Reaſons he who has a mind to make Bricks upon his own Ground, needs not be diſheartened whatever be the firſt Appearance of the Clay, for where there is almoſt any Sort it may be done. The very foul and brittle Kinds are the only ones that can't be uſed for this Purpoſe: otherwiſe they may be either wrought alone, or mended with Dirt or Aſhes, or one Kind will mend another.

I have obſerved in ſome Places, a yellow Clay with a ſmall Admixture of Sand in it, this is ſo little that it does not deſerve to give it the Name of a Loam. This is an excellent Earth in Pottery. It often lies in STAFFORDSHIRE near the Surface, ſometimes on the Surface of the Ground; and they make Mugs, Diſhes, and a very good Kind of Earthen Ware of it alone. It is ſo firm that it works well; and another good Quality is, it takes the glazing excellently.

The red Clay being firmer than this yellow Kind, one would ſuppoſe it would make a ſtronger Ware: but I have obſerved the contrary, where they work the beſt of the red Clay ſingly into any of the tolerably fine Ware, it does not take the Glazing well, and it is very brittle.

The very tougheſt and fineſt of all the STAFFORDSHIRE Earths, of which they make ſuch Advantage in their Potteries, belongs in ſome degree to the yellow Clay Kind. It is a pure, tough, and firm Clay, but is not uniform in Colour, being mixed and ſtreaked with white. This they call Bottle Clay in that County, and value it more than any other for the Body of their Ware.

Thus much I have thought needful to obſerve in reſpect to the two firſt Kinds of Clays, that

the Perſon in whoſe Hands they may chance to lie, may underſtand their Nature and Uſes, and conſequently their Value. That he may not overlook through Ignorance, ſuch as are worth his Conſideration, nor be inveigled by ſcheming Perſons, to undertake Works for which they are not fit.

As to Bricks wherever there is a tolerably good Clay, they may be made one Way or another, as deſcrib'd already: as to the Potteries, there is more in the Mixture of different Kinds of Clay, than in uſing any ſingly. But it is certain that the fine STAFFORDSHIRE Bottle Clay, which is the Ground Work of their Pottery, is to be found in other Places; for I have met with it in WORCESTERSHIRE, LEICESTERSHIRE, and HAMPSHIRE.

Under the Head of BLACK CLAYS, we uſually comprehend all that are of a dark Colour, the blueiſh and dingy, as well as the entire black, which is leſs common.

The blueiſh black Clay, which is the moſt common Kind, uſually lies at ſome Depth; but it generally makes Amends for the Trouble of getting at it by the Thickneſs of the Bed. It is a pure, hard, and tough Clay: its general Uſe is for making of Tiles for Houſes, and it has thence got the Name of Tile Clay.

There is at leaſt as much Toughneſs in this as in the red Clay of the firmeſt Kind, but they are contented to work it without Aſhes or Dirt, becauſe they are paid a better Price for the Tiles, and becauſe they require to be ſtronger, and of ſounder Materials, as they are more expoſed to Weather, with a thinner Subſtance.

There is alſo another Reaſon why they work this tough Clay entire, and without Adulteration for Tiles. They muſt be made of an Earth that will bear bending, for the Ridge and Gutter Tiles require this in a great Degree, and no Earth will bear this that has any great Mixture of Sand or Dirt: they therefore are honeſt thro' Neceſſity in this Caſe, and uſe the Clay pure.

The red and the yellow Clays often riſe to the Surface in ſuch a Degree of Foulneſs, that it is poſſible either to cut them as Clay, or to cultivate them as Soil at the Owner's Choice; but it is not ſo with the black. Where that is ſo mix'd that it can be cultivated, it is never worth taking up as Clay; and where it is ſo pure that it may be us'd as Clay in Manufactures, it is very rarely worth the Expence and Pains of Cultivation.

Beſide Tile-making which is the general Uſe of this Kind, they in many Places work it into a Sort of Pottery; when us'd alone it makes but an indifferent Ware; but being mix'd with other leſs compact Kinds, it gives a great deal of Strength and Firmneſs.

In NORTHAMPTONSHIRE they have a Clay that is quite black, and the Uſe they make of it will ſeem at firſt Sight extraordinary, they make Tobacco Pipes with it: but it burns to a perfect Whiteneſs.

This Clay is dug near the Town of NORTHAMPTON, and was one of the firſt uſed to this Purpoſe in ENGLAND. It is a fine, ſmooth, ſoft Clay, of a deep black, free from any Admixture of Sand. It is very heavy, and is naturally ſo hard, that they are oblig'd to ſoften it with Water to get it out of the Pit.

This is ſo valuable a Clay, that it is well worth the Owner's while to regard it very carefully if his Land promiſe to contain it. Sometimes it lies near the Surface, rarely at any great Depth; and it is uſually in vaſt Cakes or Benches, and not in a continued Bed.

It is not confin'd to the Place I have named for Uſe, nor to the ſingle Article of making Tobacco Pipes. 'Tis carried by Land from NORTHAMPTON into all the neighbouring Counties; and is one of the principal Ingredients in the NOTTINGHAMSHIRE Potteries.

Next to this is to be named a deep grey Clay, that in the ſame Manner burns white, and is uſed alſo for Tobacco Pipes. It uſually lies near the other; and ſcarce differs at all from it, except in the Colour.

There is a black Clay found in many Parts of ENGLAND, which is as fine and as tough as the former of theſe, and would anſwer the ſame Purpoſe of Pipe-making, but it burns red. This makes an excellent Kind of red Pottery, and is uſed in many Parts of ENGLAND. The Farmer will not be able eaſily to know one of theſe Kinds of black Clay from the other by the Eye; but if his Land affords a black Earth of ſuch a Kind, he needs only put a Piece of it into the Fire: if it burn white it is the Pipe Clay; if red, the Potters Kind, but either is very valuable.

As I include the blue among the Liſt of black Clays, I muſt here name another very valuable Kind; it is of a duſky Lead Colour, and is one of the better Sorts of the STAFFORDSHIRE Earths. They there call it by an odd Name, white Clay; but this is becauſe it makes what they call a white Ware. This is not abſolutely white neither, but of a pale yellow; however, it is the lighteſt colour'd of any they make, ſo they give it this Name.

The Owner of a Piece of Land where this Clay is found, poſſeſſes alſo a Thing of Value. He will in a great Meaſure judge of it by its Colour, which is particular, but if it become of a pale yellow when put into the Fire, he is ſure to be right. If there be a Pottery within any tolerable Diſtance it will ſell well.

In the laſt Place is to be named a medicinal Earth of this Kind; it is a black Clay of a fine Texture, which burns to a pale grey, and is good againſt Purgings, having the ſame Virtues with the Lemnian Earth and Bole Armenick.

The WHITE CLAYS are of as great Uſe and Value as any of the former. But they differ more in their Nature than any of the others: ſome of them being as tough as the pure black, and tenderer than any of the other colour'd ones whatſoever.

I have mention'd juſt now a black Clay that is us'd in NORTHAMPTONSHIRE for making of Tobacco Pipes; but the Clay that is commonly us'd for that Purpoſe is white. All that is ſold under the Name of Tobacco Pipe Clay in LONDON is white; and the fine Pipe Clays of POOL in DORSETSHIRE, and of the Iſle of WIGHT, which are the two moſt famous Kinds in the World, are alſo white.

The

The Pipe Clay of the Iſle of Wight, is of a beautiful clean white, and as tender almoſt as Marle: that of Pool is of a leſs pure white, and of a tougher Conſiſtence. Neither of theſe do ſo well as a Mixture of both, which is the common Way of uſing them. The People who ſell the Clay to the Pipe-Makers, temper one with the other till they bring the Mixture to a due Conſiſtence.

The black Tobacco-pipe Clay of Northampton is carry'd as far as Oxford, among other Places, and there it is uſed for Pipe-making, mix'd with a white Clay that is dug on Shotover Hills; which laſt is a tolerable fine Clay, but has not the Conſiſtence of the Northampton Kind.

The Reaſon why I have been thus particular is, that the Perſon who finds a Clay upon his Land, which has any Appearance of anſwering the Purpoſe of Pipe-making, may not be diſhearten'd, if upon getting a Tryal made the Workmen ſhould tell him it is too brittle or too tough; or ſhould find any other Fault with it as to the Conſiſtence.

Pipe Clay is a Thing of Value, wherever it is found, for it is one of thoſe Earths that ſell at ſuch a Price they will pay Carriage: and the Owners may ſee by this, that if it be of the genuine Pipe Clay Kind, it is worth Money, for mixing with others that may be faulty in the oppoſite Extream, even though it cannot be uſed in the Manufacture alone. He will be able to gueſs, whether it be of the Pipe Kind by this, that it is not ſo heavy and tough as the other whitiſh Clays, and is of a cleaner Colour.

There is another Kind of white Clay, which it is worth while to ſeek after, if there be any Probability of its being found in the Land; this is what the Staffordshire People call hard-fire Clay: it is of a dull white Colour mix'd with a great deal of yellow.

This does not greatly differ from their Bottle Clay, which is yellow ſtreak'd with white. The principal Difference is, that in that Kind the yellow Part is greateſt in the Mixture, and in this the white.

This is of great Uſe in their Potteries, being one of their beſt Earths.

I obſerv'd it is worth while to ſeek after theſe Clays, if there be any Probability of finding them on the Land: for very often they may be diſcover'd, although they do not riſe to the Surface: if the Plow cutting deeper than ordinary at any time turn up a Piece of Earth of any of theſe Colours, though it be foul and ſandy, 'tis worth while to open a little Pit in ſome Corner of the Field, and examine how it is deeper. Very often the beſt Beds of theſe valuable Earths are foul at the upper Part from the Soil that lies over them; though they are found altogether pure at a greater Depth.

The ſame Sort of white Clay that is uſed by the Pipe Makers, is alſo uſed in ſome Quantity by the Sugar Bakers, in the refining of their Sugars. They temper it to a juſt Degree, and lay it on the Top of the Sugar Pot, from whence the Water ſoaking gradually through the Sugar, carries off all Foulneſs with it. A very fine Kind of Bricks may be made of the tough white Clay, but few will be at the Expence.

Indeed he who finds a Clay of a good Kind upon his Lands, miſſes a Treaſure if he neglects to dig it. He cannot expect to know at once, all the Uſes that can be made of it: Prudence ſhould direct him to offer it to the Manufacturers of the ſeveral Kinds, that if it do not ſuit one he may have his Chance with another. And when he finds any one ready to bargain, let him take Care how he parts with his Property in the Grounds.

CHAP. II.

Of the Uſes of Loam.

I Have mention'd among the ſeveral Uſes of the Clays, that of making Bricks, of which there is ſo vaſt and continual a Conſumption: but the Earth of which they are principally made is Loam.

The tough Clays are to be work'd up with Sand, Dirt, or Aſhes, to fit them for Brick-making; and the Loams are Earths thus ready prepared to their Hands, ſo that all that previous Expence is ſpared. Loam is a Compoſition of Clay and Sand made by Nature, and this anſwers to the artificial Mixtures of Clay, and the before named Ingredients.

In ſome Places the Loam is ſo favourably mix'd by Nature, that it requires only to be beat together, and work'd into Bricks; and it is a farther Advantage that this Earth uſually lies near the Surface.

It is not ſtrange this is prefer'd to the ſeveral tough Clays which are dug at greater Depths, ſo that the firſt Charge is more; and which are after this to lie expos'd to the Air ſeveral Months, and then to be made up with other Mixtures.

Where there is fine Clay there ſeldom are any Beds of Sand near; on the contrary, where there is Loam, there is commonly looſe Sand not far off. This is another Advantage, becauſe Sand is very neceſſary in Brick-making.

As Bricks are intended for different Uſes, and to be ſold at various Prices, they are made from different Materials, or at leaſt different Mixtures: the hardeſt Kinds are made almoſt of pure Clay, the ſofteſt and worſt are made of the baſeſt Mixtures, as Loam and Street Dirt: ſome are ſo bad, that they will hardly hold together.

What they call Clinkers, and uſe for the Flooring of Ovens, and other ſuch Work, are made of a tough whitiſh Clay without any Mixture.

The fine pale yellow Bricks we ſee in ſome well built Houſes, are made of the ſame Sort of yellowiſh white Clay, with a little Mixture of Sand; and theſe have four Times the Labour of the ordinary Bricks beſtow'd on the tempering them. They ſeldom are perfectly good unleſs a very large Price is paid.

The fine bright red Brick which is uſed as an Ornament about Doors and Windows in many Places, is made of a pure and unmixed Loam, which contains a large Proportion of Sand,

Sand, and that very hard and ſharp, to a ſmall Quantity of Clay.

The Manufacture of the common coarſe and cheap Bricks I have ſhewn already.

Though Clay alone will therefore make good Bricks, yet as many of the very fineſt, and almoſt all the ordinary Kinds are made of Loam; this was the proper Head under which to conſider them.

A browniſh Loam is moſt commonly uſed for Brick-making; and when a loamy Soil of this Complexion is too poor for Cultivation, it ſeldom fails to offer the Owner this Uſe. But as it is a very common Earth, the Queſtion will be, Whether the Situation is likely to occaſion a Demand for them: for neither the Earth, nor the Bricks, will pay any long Carriage.

A yellowiſh Loam is after this, the moſt frequent Kind uſed in Brick-making; and ſometimes it affords a Brick that is of value enough to merit Conſideration. The Owner of Land where ſuch a Loam turns up, will do well to try it in the Fire. A ſmall Piece of it will make the Experiment; and if it burn quickly to a high red, it will be worth his more ſtrict Trial, as it may afford the fine red Brick, which is always beſt when made of this Loam pure, tho' ſome uſe Mixtures.

A blue and yellow brittle Clay is common in many Parts of ENGLAND, with a ſlight Admixture of Sand in it. This they make into Bricks in OXFORDSHIRE, LEICESTERSHIRE, and many other Places, and they are much better than the common Rate of Bricks in LONDON.

In WILTSHIRE they uſe a yellow clayey Marle for Brick-making, and it anſwers tolerably well. It is tender, and works eaſily. The Bricks are about as good as the midling Sort in LONDON; and they are better made, for there is no Place where Work is done in ſo ſlovenly a Manner.

I have ſeen alſo a browniſh marly Clay uſed in other Counties to the ſame Purpoſe, and with about equal Succeſs. Theſe Earths work well, but the Marle is no good Ingredient, and makes the Bricks brittle.

About NEWCASTLE in STAFFORDSHIRE, they make Bricks of a brown Loam, which burns blue. Theſe have an odd Appearance, for blue Bricks are uncommon, but they are ſtrong. The ROMANS ſeem to have prefer'd this Earth to many others, uſing it for their Urns; many of thoſe found in KENT, and other Places, being of this blue Colour.

I infer from this, that probably the Earth of which they are made, is found in the ſame Places. This is worth ſome regard as it is of no inferior Kind for Brick-making.

Though the making of Bricks be one of the principal Uſes of Loam, and is far from being the only one. Loams of many Kinds, when they are of a due Toughneſs, which is owing to their having a large Proportion of Clay, are uſed in the Potteries of different Counties; and in other Places where they are not of a Firmneſs to enter into the Compoſition of the Body of the Ware, they are uſed in the Painting of the Outſides of the ſeveral Kinds.

In STAFFORDSHIRE, where they are particularly curious in enquiring into the Nature of their Earths, they diſtinguiſh thoſe they uſe in the Pottery into two Kinds; the firſt they call throwing Clay, the other Slips.

The throwing Clays are ſuch as are tough, and will work upon the Wheel; theſe are all Clays, and they make the Body of their Work. The Slips are ſuch Earths as are brittle, and theſe they uſe in Painting and Colouring the others. Theſe are principally Loams, but they prepare them for Uſe by firſt mixing them up in Water, and letting all the Sand ſubſide, ſo that they take only the pure Clay that was in the Compoſition.

There is a grey Earth with Lumps of yellow among it, frequent in that County; the which I have ſeen alſo in LEICESTERSHIRE, WARWICKSHIRE, and elſewhere; this is a dirty Loam. They prepare it as before obſerved; and when the pure Clay is mix'd up with Water to the Thickneſs of a Syrup, it gives the deep yellow to all their Ware.

They uſe a blueiſh Loam, which has ſo little Sand that it might be called Clay; for a paler yellow, having prepared it in the ſame Manner. And, finally, they uſe a great deal of a duſky reddiſh Loam; which, when treated in the ſame Manner, gives the black Colour.

The laſt of theſe Earths is common in half the Counties in ENGLAND; the blue is leſs frequent, but I have ſeen it in WORCESTERSHIRE and elſewhere. All theſe Loams may have their Value if a Pottery ſhould be near, and they ſhould be wanted upon the Spot, otherwiſe they do not demand much Notice.

But there is yet a Loam to be ſpoken of; which, whenever it ſhall be found, will be an Eſtate to the Owner, and alſo a Benefit to this Country. This valuable Kind is what they dig at preſent only at the Village of HEDGERLY in BUCKINGHAMSHIRE, upon the Edge of BERKSHIRE. They call it there Fire Earth, and the Bricks they make of it Fire Bricks; this Name is given them from their great Strength in bearing the Fire: in LONDON the Earth is known by the Name of WINDSOR Loam, and ſells at ſo large a Price as Ten-pence or a Shilling a Buſhel.

They call it WINDSOR Loam, becauſe it comes from WINDSOR to LONDON, HEDGERLY being only a few Miles from WINDSOR.

This valuable Earth is a true Loam, and one of the harſheſt in the World; it is of a browniſh yellow Colour, very coarſe to the Touch and brittle: being put into the Fire it becomes of a fine ſtrong red.

Theſe are the Marks by which it is to be known, and it cannot be too diligently ſearched for; the Vein of it at HEDGERLY being in Danger to be worked out, from the great and long Conſumption. The Perſon who works it at preſent having dug for it all the Ground he had, took another Acre for the ſame Uſe ſome Time ſince at a great Price; but on digging he has found the Bed of it does not continue.

The Uſe of this Earth is to face the Ovens at Glaſs-houſes, and for all other Service where there is a great Violence of Fire. The Chemiſts, Refiners, and others, uſe it alſo to cover their Glaſſes, and other ſuch Work. And the Bricks made

made of it are the only ones to build the Ovens and Furnaces themſelves, nothing ſtanding the Fire comparably to it. This Earth whether in Bricks, or in the Coatings before nam'd, will preſently turn to a fine red Colour, and then will ſtand many Years unalter'd, where a Piece of common Loam would be run into Glaſs in a Minute.

Yellow Loams are very common: and it is highly probable, not to ſay certain, that this particular and valuable Kind is produced in other Parts of the Kingdom, beſide juſt the Spot which now ſupplies not only all this Kingdom, but ſeveral others, for a great deal of it is exported, for the Purpoſes of Glaſs-Makers, Melters of Metals, and the like.

Every harſh yellow Loam may be try'd for this Uſe, comparing it firſt with the HEDGERLY Kind, and then making it into Bricks: for the Bricks made of the right Fire Earth, when properly burnt, are as red as thoſe ſoft ornamental ones already mentioned.

Not only a Bed of this Earth may be ſomewhere diſcovered to the great Profit of the Owner; but by frequent Trials perhaps a Loam may be made artificially, which will anſwer the ſame Purpoſes. The only Ingredients Nature has us'd in this are a very ſharp, hard, and large Sand, of a pale browniſh yellow Colour, and a yellow tough Clay. Now if ſuch a Sand ſhould be found in one Part of the Kingdom, and a Clay of exactly the ſame Kind in another ever ſo diſtant, they might, on being mixed in a proper Proportion, make exactly the ſame Loam that is dug in this particular Place. If the proper Kinds of Sand and Clay ſhall be once found, the Proportions will eaſily be diſcovered by making a due Number of Tryals.

Thus not only the Loam of HEDGERLY is to be ſought for in its own Nature in other Places, but Sand Pits and Clay Pits are to be ſearched on this Occaſion with a reaſonable Hope. If the Sand be found in one Place, the Clay may be found upon another on the ſame Eſtate, or in the Neighbourhood.

What makes me the more ſtrenuouſly recommend this double Search is, that in the Piece of Ground newly taken by the Man of HEDGERLY, into which the Bed of Loam does not run as he expected, there is found a Bed of yellow Clay, and another of a pale colour'd harſh Sand, which are evidently the Things of which the Loam is compos'd in the other Pit. And a Gentleman of LONDON, very curious in theſe Things, aſſur'd me, that by mixing theſe together, he had made a Loam altogether like the other, and of equal Uſe for the ſame Purpoſes.

The Sand is alſo in ſome Places found looſe in the right old Loam Pit; and there are Parts of the Vein which have a great deal of Clay, and Parts which have very little, being almoſt entire Sand, and ſcarce capable of holding together. The Workmen work all theſe together, and perhaps ſometimes mix ſome of the Sand with them; beating up all together to a due Form, which they from long Experience know by the Eye.

All this leads me to believe the Mixture may be entirely made by Art, and he will be happy who finds the Method.

CHAP. III.

Of the Uſes of Sand.

CLAY is the Earth which is employ'd to the moſt Purpoſes beſide thoſe of Huſbandry; and the next in Uſe to it is Loam: That has not nearly ſo many as Clay; and the other Kinds to be treated of, have much fewer than either. In the ſucceeding Chapters I ſhall conſider Sand and Gravel. Theſe are ſomewhat of kin to one another in their Nature, Sand being little other than a ſmaller Gravel; and Gravel little other than a larger Sand; and ſome of their occaſional Uſes are the ſame.

Where either bare Sand or bare Gravel are at the Surface taking the Place of Soil, they are not worth Culture: the Owner is therefore to enquire what Uſe he can make of them. And this will be greater or leſs according to the Situation of the Place where they lie, more than to any thing of Variation in their Kinds.

Sand is us'd as a Manure to Clay Grounds in ſome Places, and that with good Succeſs; and, as has been ſhewn, this is a Practice founded on Reaſon.

The various Kinds of it alſo are us'd to many other leſſer Purpoſes, for which they are ſeverally ſuited by their Fineneſs, Coarſeneſs, and other Accidents.

In BUCKINGHAMSHIRE the fine white Writing Sand, which is elſewhere ſold at a conſiderable Price, is ſo common, that they ſtrew Rooms with it, as in other Places they do with the ordinary yellow Sand.

In many Parts of MIDDLESEX, there is a ſmall deep yellow Kind, which feels like fine Powder to the Touch, having ſcarce any Sharpneſs. They make no Profit of it there: but the ſame Kind of Sand is ſold at a great Price at BILSTON in STAFFORDSHIRE, where there are ſome Pits of it; for the Uſe of People who caſt Metals.

Pure white Sand is us'd in making the fineſt Glaſs. It in this Caſe perfectly well anſwers the Purpoſe of Cryſtal; being better than Flints. For indeed white Sand is no other than ſmall Pieces of Cryſtal, juſt render'd cloudy by a white Earth; as the other Kinds are colour'd, and more debas'd in their Nature by yellow or reddiſh Earths.

Clean Sand, and of various Degrees of Fineneſs, is alſo uſed by Glaſs Grinders: and the finer Sorts by Plumbers for making the Bed on which they caſt their Sheet Lead.

In STAFFORDSHIRE alſo they ſift a Kind of yellow Sand, firſt from the Duſt and ſmall Pieces in a fine Sieve, and afterwards from the Stones, or ſmall Pebbles that are among it in a larger; and having thus brought it all to an even Size, they ſpread it upon Boards, and whet their Scythes on it: from this it has the Name of Scythe Sand, by which it is known throughout that County.

It is uſual to diſtinguiſh Sand into three Kinds; Pit Sand, River Sand, and Sea Sand,

The Pit Sand and River Sand have no other Difference but this, that the River Sand is well waſh'd, and the Pit Sand has often a great deal of Dirt among it. There are as many Kinds of one as of the other, and of as many Colours; but this is all the Difference, for the River Sands are waſh'd out of the Banks by the Water.

Sea Sand is often in its Original of the ſame Kind with that of Rivers, but it uſually has ſome Fragments of Sea Shells mixed with it, the Waves waſhing them to Pieces on the Shore. In ſome Places what they call Sea Sand is made up almoſt entirely of theſe. This is uſed as a Manure to Land in ſome Counties, and gives it a great Richneſs and laſting Fertility.

The common Sand when us'd as a Manure, can anſwer no other Purpoſe but ſolely that of breaking the Clay: but this which is of an Animal Nature, operates as all the other Animal Subſtances; and by its Saltneſs.

CHAP. IV.

Of the Uſes of Gravel.

THE Uſes of Gravel for Walks are ſufficiently known; but the ſeveral Kinds of it differ exceedingly in their Value. This is not owing to any Thing in the Body of the Gravel itſelf, but to ſuch Mixtures as Nature chances to have thrown among it in the Beds.

All Gravel is made up of ſmall Pebbles and Flints, but in ſome there are fewer of the Flints than in others, and in ſome Beds of Gravel there are almoſt none; and ſo of the other Mixtures.

Some Pits afford a Gravel made up only of roundiſh Pebbles of a bluiſh red Colour. Theſe look as if they had been waſh'd, having no other Matter of whatſoever Kind among them.

A Pit of this is hardly worth opening, for it is a Kind of Gravel that from its own Nature can never bind; nor is it poſſible to add any Thing, except in a vaſt Quantity indeed, that will make it. A Walk laid with this ſeems compos'd of looſe Stones, and always continues uneven, and troubleſome to walk upon; neither is the Colour agreeable.

In other Pits we find Gravel that has a great many Flints, and a great deal of Sand among it; and in this the very Pebbles are uſually of a paler Colour. This does a great deal better for all Purpoſes of laying Walks, becauſe the Flints and Pebbles not being all round, come cloſer together, and the Sand fills up in ſome Degree the Crevices between them.

Theſe Gravels, however, bind but moderately; and often the Sand will be waſh'd away by hard Rains, and leave Spaces empty between the Stones.

The beſt Kind of Gravel of all, is that which is compos'd of ſomewhat irregular Pebbles, with a great many Flints, and with a good deal of a marley Loam among it. This is the fine Gravel of our Kingdom; the Loam is yellow, and gives that Colour to the whole. It alſo makes it bind tight and firm, for it fills up all the Spaces between the Stones, and the Clay that is in its Compoſition keeps them all firm; and prevents the Sand from riſing in dry Seaſons.

Theſe ſeveral Kinds of Gravel may be ſcreen'd to what Degree of Fineneſs the Purpoſe requires: and the Owner who ſees to what the Excellency of the beſt Kinds is owing, may here as well as in other Caſes, imitate Nature, and improve the others.

I would not have him undertake ſo bad a Taſk as to make a good Gravel out of the round clean Kind firſt named, by adding any Thing to it: but if his Land afford in any Part a Gravel that is pretty good; and there be a Demand for it, he may add Cent per Cent to its Value by a little Trouble.

If it be too apt to throw up the Sand in Duſt in dry Weather, let him order ſome tough Clay firſt temper'd ſoft with Sand, and Water, to be thrown and ſtir'd well in amongſt it: or if he have ſome that wants only a little more Loam, let him add it freely, this will give what they want, and convert ordinary into excellent Gravels.

Among the Gravel there are in moſt Places dug up a Sort of large ſmooth Stones of the Bigneſs of a Man's double fiſt, or near: theſe are no other than the ſame Pebbles that are in the Gravel only larger in Size, and they are be ſeparated for other Uſes, Gentlemens Court Yards are often pitch'd with them; tho' they make but a looſe diſagreeable Pavement.

The Value of theſe, like that of the Gravel itſelf, depends upon the Situation of the Place, and the Demand.

In ſome few Places, and particularly in Buckinghamshire, I have ſeen the Farmers dreſſing their Clay Land with Gravel. I went up to an old Huſbandman whom I ſaw aſſiſting in ſtrewing Gravel thin over one of theſe Lands, and he aſſured me it had been done by a Neighbour with good Succeſs.

The Land was a ſolid red Clay without Sand or Stone, and the Gravel was a very loamy Sort well ſcreen'd, ſo that there was not a Stone ſo big as a Walnut among it. However ſtrange the Practice might appear at firſt: for indeed it look'd as odd to me as it poſſibly can to my Reader, yet on conſidering theſe Points, it was not foreign to Reaſon.

The Stones in it were moſtly ragged little Flints, and along with theſe there was a great deal of a marley Loam: for the Loam that is among Gravel, is uſual of the marley Kind: theſe Flints broke the Subſtance of the Clay, and made way for the Sand, which broke and divided it ſtill farther; and ſo let in the Marle that enriched it, at the ſame Time the Openneſs of the Structure gave Admiſſion to the Sun, Air and Rains.

The old Farmer told me that all he ſhould do more to his Land, was giving it a ſmall ſprinkling of Dung from his Yard toward Michaelmas; and he aſſured me this was the Method follow'd by his Neighbour, who had by that Means got good Crops of Wheat from a Piece of Ground, which had many Years had the Character of one of the worſt Pieces of Land in the Hundred.

Gravel is one of the great Advantages we have in this Country over moſt others for making Walks; and it is from this, and our Graſs or Green Sward, which is in the ſame manner ſuperior to that of all other Nations, that we are able to add a Beauty to the Walks in our Gardens, which no other People can.

Now ſo far as regards the Gravel, this Advantage is owing in a great Meaſure to the Mixture of thoſe other Ingredients Loam and Sand among the Pebbles, than to the Pebbles themſelves. Other Countries have Heaps and Beds of ſmall Stones, but they are deficient in theſe Admixtures which make them bind.

But as famous as we are in ENGLAND for Gravel, it is not in every Part that we have it, or that the People know it ſo well. They even give its Name to other Things, altogether different in their Nature.

In ſome of the moſt weſtern Counties there is hardly ſuch a Thing to be found as a Pebble: yet they have what they call Gravel. And in NORTHAMPTONSHIRE, where they have Pebbles enough, they yet give this Name to other Mixtures. At FARNDON in that County, their Gravel is made up of flat Pieces of Slate Stone more than Pebbles; the Gravel at UPTON is made up wholly of ſuch Pieces of Stone, without a Pebble among them: at ECTON they call a reddiſh Sand, with ſome flat Pieces of a red Stone among it, Gravel; and at DESBOROUGH they gave the ſame Name to Quantities of petrify'd Sea Shells among Sand. As they uſe theſe ſeveral Matters inſtead of Gravel, they give them its Name, but it does not properly belong to any of them.

The Gravels in ENGLAND are in Colour yellow, reddiſh, brown or whitiſh: the firſt are preferr'd, but there is a particular Beauty in the laſt Kind. There are Pebbles among them of pure Cryſtal, ſome as clear as Glaſs, others leſs pure and whitiſh. I have taken up ſeveral of theſe in a Gravel Pit near the Duke of PORTLAND's; and on one I have a Seal engraved: it is equal to any Cryſtal in the World.

The Gravel in KENT is often compos'd only of looſe Pebbles. In SUSSEX I have ſeen a great deal made up of Pebbles and Sand only, which lies looſe in Walks, and never binds; in BEDFORDSHIRE I have met with it too loamy, and this is a great Fault. Walks made with this are dirty after Rain, and are apt to be preſently over run with Weeds. A due Proportion of Loam and Sand, with the Flints and Pebbles, is the Perfection of a Gravel.

CHAP. V.

Of the Uſes of Chalk.

FEW of the Earths ſerve to more conſiderable Purpoſes than Chalk. It is therefore by no Means to the Owner's Diſadvantage to have it upon his Land any where: often it is a Subject of great Profit. In ſome Counties it is ſcarce, others are over-run with it. In the firſt a good Bed of Chalk is an Eſtate: and even in the others it has its Value.

A great Quantity of Lime is made of Chalk. It does not make the beſt Lime, but it calcines the eaſieſt, and can therefore be ſold cheaper, which never fails to procure Cuſtom.

The Uſe of Chalk as a Manure is alſo abundantly known, and occaſions a great Conſumption of it. In this Light it has been mention'd already under the Articles of thoſe ſeveral Soils which it is beſt ſuited to improve; and it will be mention'd more at large hereafter under the Head of Manures. It is however neceſſary to name it in theſe Reſpects under this general Conſideration. Theſe frequent Neceſſities of mentioning the ſame Thing endanger Repetitions; but it ſhall be our Care to avoid them as much as poſſible.

That the Owner may know to which of theſe two general Purpoſes Lime, or Manure in its own State, his Chalk is beſt ſuited, he muſt examine its Nature. A ſmall Degree of Care will diſcover this; for in general, he will find the hard and ſtony Chalks are fit for Lime; and the ſoft and marley ones for Manure in their natural Form: I ſay in their natural Form, becauſe the hardeſt of them when reduced to Lime, ſerve alſo for Manure.

Theſe are Articles no farther to be conſider'd in their Place: and the preſent Chapter will be the ſhorter, becauſe of the Neceſſity of treating largely of the Subject elſewhere.

Whiting, which is of ſo many Uſes in the common Affairs of Life, is made from Chalk. It is no other indeed than Chalk broke from its hard and firm Nature, and reduced to a fine Powder like Flower, which having been ſuſpended in Water, forms itſelf into Cakes as that Water dries away; and is fit for the Uſe of the White-waſher and others.

Chalk is alſo valuable on Account of its Qualities as a Medicine. They find in Chalk Pits certain roundiſh ſhelly Subſtances, which they call Chalk Eggs. Theſe are hollow, and full of a Chalk as fine as Whiting, and altogether like it. The Curious ſay theſe Shells once belonged to the Sea Eggs, or Sea Urchins, as they are called, a Sort of Shell Fiſh common enough on our Shores; and that they have been petrified and filled thus with fine Chalk ever ſince NOAH's Flood.

I have been told that the Chymiſts and Apothecaries uſe Chalk oftener than they ſhould: and that thoſe white Cakes that are ſet up in Glaſſes at their Windows in LONDON, with the Name of Pearls, and the like, are only Chalk. They look very like little Whiting Balls: very probably they are no other. How far this Deceit is prejudicial to the Healths and Lives of thoſe that take them, I ſhall not enquire; not being willing to ſpeak of Things I do not underſtand.

They are very happy in KENT, and ſome other Counties, who have the Chalk lying juſt under Ground, or in the Cliffs, ſo that they have nothing to do but to tear it down and uſe it. In many other Counties where they have as much Neceſſity for it, it lies at great Depths.

In ſome of theſe Places they dig Wells for it, there being no Water till they come to a great Depth, ſo that they take up a vaſt deal without

out Disturbance. In other Counties I have seen them digging for it as they do in Mines, and drawing it up in Buckets: in such Places it bears a Price.

They have a very ingenious Method in some Parts of Kent, of getting down their Chalk where it is in the Cliffs, or on the Sides of Hills, which is well worth practising in all other Parts where this Commodity lies in a like Situation. In the first Place, they undermine a Parcel of Chalk to a little Depth at the Bottom. When this is done, they go to the Top and cut a small Trench along, as far from the Edge as the Depth of the undermining: they fill this Trench with Water in the Evening, and the Effect is, that a great Flake of Chalk, of two Foot or more in Thickness, and of the whole Breadth of the Pit falls off before Morning. This does best in the hard and stony Chalks.

We hear of two other Kinds of Chalk among the Painters, the one called black Chalk, and the other red Chalk. It might be supposed that these were common Chalks ting'd to those Colours, but that is not the Case: they are altogether different Substances, and are found not in great Beds, but in Lumps: where they happen to be thrown up in diging, they are worth saving; but there is no knowing where to expect them.

Hitherto we have been considering those Sub stances which frequently make the Foundation of Soils, as they are useful to other Purposes beside those of Husbandry. We have in this Light gone through five of these: there remains one more, that is, Mould; but as the natural and immediate Use of that is for Husbandry, it would be idle to consider it in other Lights.

It will be proper therefore that we now advance to certain other Substances, which the Owner may find either by Accident, or by his Industry in his Land, and which may be very profitable.

CHAP. VI.

Of Fullers Earth.

IT would be natural in this Place to give the Preference over all other Things here to be treated of, to Marle: as it is more frequent than the others, more abundant in Quantity wherever found, and more generally useful; but that will come into Consideration in another Place, under the Article of Manures: and to avoid any Repetition, nothing shall be said of it here. I shall therefore proceed to treat of Fullers Earth; a Commodity of Value, and of the utmost Importance in that great Article our Woollen Manufactory. It is not only an Advantage to the Owner who shall find this on his Land, but to the Country.

Fullers Earth is at present dug in very few Parts of this Kingdom: but wherefoever it is found, the Profit is very great. The Nation is at this Time in a Manner supplied from a few Pits in Bedfordshire; but I have more than once met with this valuable Earth in other Counties.

In the first Place, let those who may reap the Advantage of it, know perfectly what it is. Fullers Earth is a genuine Marle, and is the finest of all the known Kinds. If the Price would allow, doubtless it would exceed all other Sorts in the Improvement of Land; none is so pure and free from Admixture, none is so soft and mellow; and as to its breaking with the Weather, we know very well that it falls to Powder in a few Moments by the Effect of Water.

Tho' Fullers Earth will never be used as a Manure, yet even the Knowledge of it is not without its Use: for foul and coarse Fullers Earth is found in Places where the fine and pure is not; and the Owner will not know how to value it.

I mentioned the Buckinghamshire Farmer's dressing his Ground with Gravel. I have in many Places found a coarse Kind of Fullers Earth in Gravel Pits: I cannot say I distinguish'd any of it in the Parcels of Gravel I saw there; but if there were any Quantity of it as there might be in other Depths of the Gravel Pit, we see the Fertility in part accounted for on this Principle. I thought at that Time this Farmer deserved particular Praise for doing what so few of his Profession ever will, and especially of the old ones, that is, use a new Method.

What I mean by a coarse Kind of Fullers Earth found in Gravel Pits is this. There often lie among the Gravel in different Counties, Lumps as big as one's Fist, or of half that Bigness, of a greyish coarse earthy Substance. Sometimes I have seen these lie irregularly, and in some Places I have seen a Streak of them in the Side of the Pit run perpendicular; though seldom in an exact strait Line from the Top of the Bed of Gravel down as far as the Workmen dig.

This coarse Earth when examined, contains usually a sharp Sand, and some Clay, but it has a soapy Softness withal, that to a Person used to handle Fullers Earth, will be sure to bring that into his Mind.

I have put these Lumps many Times into Water, where they break almost directly, and they form three Settlements. At the Bottom there lies a sharp Sand, over that is a thin Settlement of yellow or brown Clay, and at the Top of these a loose Covering of an Olive coloured light, crumbly and moulding Matter, which is perfectly the same with Fullers Earth when broke in Water. If the whole be shook or stirr'd together ever so often, the Settlement always divides itself into three Parts in this Manner.

Now I am sure from many Trials, that this upper Settlement, which looks so like Fullers Earth in a State of Wetness, is Fullers Earth in Reality; upon this it will be worth while to make some Observations.

In the first Place, where should any Thing be expected to be found pure and entire, but where we already see it in a more imperfect State. Therefore in whatever Lands these Lumps shall be found, it would be well to look heedfully all over them for more and finer, in order to direct a better Search by digging where there is a Prospect.

Secondly,

Secondly, where there are Beds of any Kind of Earth pure at ſome Depth, we ſee the ſame Things in a fouler State towards the Surface: thus clayey Soils generally lie over Beds of pure Clay; theſe Soils being no other than the ſame Clay which will be found pure at a greater Depth, mix'd with other Earths near the Surface: and it is the ſame of the others.

Therefore when we find this foul Kind of Fullers Earth near the Surface of the Ground in Gravel Pits, it is very reaſonable to believe the ſame Subſtance may be found altogether pure and entire, deeper down.

I would not adviſe for this Reaſon, the diging in Search of Fullers Earth wherever ſome of theſe Lumps ſhall be found, becauſe that would be a random Search: ſuch Marks of valuable Things under Ground, being often ſcatter'd to a great Diſtance about the Surface. But when the Owner of a Piece of Land ſees one of theſe Veins I have ſpoken of, running ſtrait down a Gravel Pit to the Depth of the digging; I think it would be worth while to venture ſome Expence in following it deeper; and ſeeing in what it ends.

The Miners often trace a Vein of Ore in this Manner through the hardeſt Rock, from the Thickneſs of a Thread till it enlarges into a great Body; why ſhould not the ſame Succeſs attend ſuch a Trial here.

I remember once to have ſeen in a Gravel Pit upon my own Land, a Vein of fine Mould thus running ſtrait down among the Stones. This did not begin ſmall and increaſe in Bigneſs; on the contrary, it was wideſt at the Top or Surface of the Ground, and grew ſmaller all the Way. I had ſeen theſe before in other Places where I had no Right to dig; but here I ordered it to be followed. At about thirteen Foot it terminated in a thick Bed of Garden Mould. The whole Deſcent ſeem'd to have been a Kind of Funnel, through which this Mould ran into the Hollow underneath, filling it up, and forming a Layer of Mould, a Thing very unuſual at that Depth.

I mention this to ſhew how well ſuch a Vein of Fullers Earth, if one ſhould be met with, would be worth following. We know nothing of the Ways by which People were led to the Knowledge of thoſe Beds that have ſo long been dug for Fullers Earths: perhaps it was in ſome ſuch Manner.

Of this I am ſure, that if the Farmer or Owner would frequently follow the Plow and the Spade with his Eye, he would find great Advantage.

This is not all the Reaſon we have to expect Fullers Earth in other Places, beſide thoſe where it is at preſent dug.

At Wendon in Northamptonshire, there is found in many Pits, an Earth of an irregular and mixt Colour, yellowiſh in ſome Places, and blueiſh in others. This breaks in Water juſt like Fullers Earth, and takes Spots out of Cloaths, as the People every Day experience. It is not altogether pure, nor does it ſeem of quite ſo ſcouring or penetrating a Nature as Fullers Earth: but it comes very near it, and ſerves in its Place for ordinary Purpoſes.

Now blue and yellow mix'd, every one knows make green. Theſe dingy Earths therefore would probably when mix'd, make an olive Colour; and if pure, would more reſemble Fullers Earth. This is not the only Place where I have ſeen this foul and half-mixed Earth: is it not very probable that the ſame Earth more pure and better blended is to be found a little deeper? Such a one would be right Fullers Earth; but no-body digs to try.

Dr. Plot in his Natural Hiſtory of Staffordshire, ſays, That near Statfold in that County, he had met with Fullers Earth very much like that of Wooborn in Bedfordshire, but in little Quantity. Now if ſome broken Maſſes of this lie near the Surface, who will doubt but there are more at greater Depths. Probably there are Beds of it there, and in the other Places I have mention'd, and there only wants Induſtry and Spirit to open the Way to a Fortune.

I would adviſe the Land Owner and Farmer for the future, to make themſelves well acquainted not only with Fullers Earth, but the others to be named hereafter, by the Sight and Touch; that they may know when any Thing like them happens to be thrown up: I ſay any Thing like them, for they are not to expect to find any of theſe Commodities pure and perfect when near the Surface: they can only expect coarſe Pieces there which may tempt them to ſeek farther; they are to expect no more than this, for it is all Nature gives for their Information.

CHAP. VII.

Of Ochre.

OCHRE is an Earth uſed by Painters and many other Artificers; and is of very conſiderable Value. Many fine Kinds of it are produced in England, and that in very large Quantities. It is an Eſtate to the Owner wherever it is found; and I am ſenſible, that it is to be dug in many Places, where at preſent the Poſſeſſor of the Ground has no ſuch Expectation.

Ochre is of ſeveral Kinds: the two principal are yellow and red. A great deal of the yellow Ochre is converted into red by burning, for all yellow Ochre grows red on being put into the Fire; but beſide this, there is natural red Ochre in Abundance.

Beſide theſe two principal Kinds uſed by the Painters, of each of which there are ſeveral Subdiviſions; there are two others uſed by Glovers in ſome Parts of the Kingdom, and not ſo well known as they deſerve to be: in others there are a purple and an aſh-colour'd Kind; and to theſe four I may reaſonably add a fifth, which is of a duſky Straw Colour, and ſerves for the rubbing upon Leather Breeches, and Buff-Belts.

It is not to be imagin'd, that every coloured Earth is an Ochre: on the contrary, an Ochre is an Earth of a diſtinct Kind from all others. As Clay differs from Chalk, and as might be inſtanced of many others; ſo Ochre differs in its very Nature from any other Kind that can can be named. There are indeed clayey Ochres, but they

they are the leaſt valuable Kinds. Ochre in its proper Condition, is light, brittle, duſty, and fine between the Fingers; and ſuch are all thoſe I have named.

As to the yellow Ochre, which is the moſt univerſal Commodity, that is dug principally on Shotover Hills near Oxford: not only all England, but all Europe is in a Manner ſupplied from this Spot; but the Owner of a Piece of Land where Ochre ſhall be found, needs not for this neglect digging it. For tho' People are principally ſupplied from Oxfordshire with it; a great deal is ſent to London from other Places; and wherever it ſhall be found, a Market may be had for it.

The ingenious Dutch have a great deal of our Ochre from Oxfordshire, which they partly uſe for their own Purpoſes, and partly ſend over to us again after they have manag'd it different Ways, under the Name of foreign.

Yellow Ochre uſually lies under Beds of Clay and Sand: but it generally diſcovers itſelf by Lumps lodged here and there among thoſe Beds: ſo that when ſuch are found among Clay or Sand, of a good Colour, and in any Quantity, it is worth while to be at ſome Pains and Coſt to ſee farther.

The yellow Ochre is divided into two Kinds in theſe Pits; one called Stone Ochre, and the other Clay Ochre; one is ready for Uſe juſt as it is dug, being naturally pure and fine; but the other is foul and irregularly colour'd; ſo that they ſoak it in Water to get out the Sand, and then beat it into Cakes.

In many Places yellow Ochre is found in little Lumps among Gravel, and of different Colours. They pick ſuch up in Bedfordshire and other Counties, and the Glovers uſe it. I have often ſeen this of fine Colours.

In Northamptonshire, and ſeveral other Counties, they have grey or aſh-colour'd Ochre; the purple is not ſo common, but they find it in the firſt mention'd County. Particularly in a Pit at Thingdon, there is a thin Stratum of it. 'Tis uſed only by the Glovers, and therefore ſells at a ſmall Price: but it is worth the Notice of Painters, for it is a beautiful Colour, not unlike what is called Perſian red; and mixes well with Oil, as I have tried many Times.

It is not difficult to make a gueſs where Ochre is under the other Beds; by theſe Tokens it gives of itſelf nearer the Surfaces, and 'tis often worth the purſuing at ſome Expence. But it is not only the Want of attending to theſe Marks, that is to be charged upon many of the Owners of Lands, I have known a Bed of yellow Ochre cut through in digging for Water; and neither the Farmer nor Landlord have known, that the yellow Matter they ſaw thrown up was of any the leaſt Value.

The Chapter of Ochre is not to be cloſed without mentioning what is called Reddle. This is not indeed properly of the Ochre Kind, but a Marle of a deep and ſtrong red Colour; but as it is vulgarly called an Ochre, and by ſome red Ochre, as if there were no other, it was neceſſary to mention it here.

The fineſt of this Reddle, and the greateſt Quantity, is dug in Derbyshire, from whence it is ſent to London, and to other Parts of the Kingdom, where ſo large a Quantity of it is uſed, that though it ſells at a ſmall Price, the Value is upon the whole very conſiderable.

Beſide the common Uſe in marking of Sheep, this Earth is put to many others among the Colourmen, being the Foundation of a great many of thoſe Compoſitions that ſerve for large Work.

CHAP. VIII.

Of Peat.

PEAT, or as it is called in ſome Places, Turf, is a very particular Subſtance. It is ſufficiently known by Sight in the Places where it is burnt, for it is the common Fuel of many Counties; but I have found many even in thoſe Places ſtrangely ignorant of its Nature; and thoſe in remote Counties very little acquainted with it more than by Name.

It is not much a wonder that thoſe who never ſaw Peat except in the dry State, ſhould be ignorant of its Origin. It then is of conſiderable Hardneſs in many Kinds; but the moſt ſolid Peat cuts eaſily with a Spade in the digging, being ſoft and tender there, though it get Firmneſs in drying.

Peat, or as it may be called Peat Earth, diſtinguiſhing that which lies on the Ground from that which is dug, conſiſts of a bituminous Matter, full of various Parts of Plants. For this Reaſon when cut up and dry'd, it readily takes Fire, and burns very freely.

It is of two Kinds. The one is taken from the Tops, the Sides, or the Bottoms of Hills; the other is dug up in a level Country. The Peat of Lancashire is of the firſt Kind; and that of the Fens, as of Lincolnshire, and the like Places is of the other. They differ in Colour, that of the hilly Countries being pale; and alſo in Conſiſtence, as it is ſomewhat ſofter. The Peat of the Fens being compact, of a deep blackiſh brown, the other lighter, looſer, and of a paler Hue.

Theſe are but trivial Differences, and in all other Reſpects they are perfectly alike. The bituminous Matter is the ſame in both, and the Parts and Remains of Plants are of the ſame Kind, and preſerved in a like Manner.

It is in many Places of great Conſequence to the Owner of Land, to know whether Peat may be cut in it. This, as it lies ſo near the Surface, and as the Soil about it uſually ſo eaſily diſcovers it, is not ſo often over look'd as Ochres, and the reſt of thoſe valuable Earths that are hidden at greater Depths; yet I have ſeen where a great deal has been loſt by not attending to theſe obvious Diſcoveries of Nature.

Let all thoſe therefore who live in Places where Peat is at all likely to be found, acquaint themſelves with its Nature, with the Marks of the Soil that contains it; and with its Value. That they may judge where it is lodged, and whether worth taking up.

The Fen Lands are the Places where Peat is moſt frequently found, yet it is not univerſally laid

laid under all fenny Soils. Some Parts of the Fens in the Iſle of Ely, in Lincolnshire, and Northamptonshire, afford it in great Plenty and Perfection. Other Parts of the ſame Fens none at all. Very frequently the Farmer lights on it in digging his Ditches, which are the common Fence in that Country: and then the Peat very well pays for all the Labour of digging.

The right Peat Earth is a light, ſpungy, tough Subſtance; of a blackiſh, or a darker, or lighter brown Colour. It is full of fibrous Roots of Plants, together with flaggy Leaves, and hollow Stalks like Reeds; and has often many other Parts of Plants in it. Theſe Vegetable Matters are ſo abundant in the Peat Earth, that it ſeems as it were compoſed of them.

It lies at ſmall Depths in the Earth, but never on the Surface of it, as ſome from the Name Turf have been idly led to imagine.

It never lies immediately under the Turf or Sward, but always has a greater or leſſer Depth of the Soil between. This Soil is commonly the black moory Land, or pure Mould of the Fens; and this is ſo unlike in its Nature to the Peat itſelf, that if it be taken up with it, as is ſometimes done in the Cutting; and Peat be laid to dry with a Quantity of the Mould upon them, it always falls off.

Good Peat Earth, as it lies in the Ground, cuts ſoft and eaſy, ſo that they form it into Shape as they dig it. When dry'd, the Peat are tough and firm, they are not eaſily broken, and the bituminous Part between the Stalks and leafy Remains of Plants is very hard; and where it is broken, looks ſmooth and gloſſy like Pitch.

The blacker the Peat is, the better it is always reckon'd: 'tis for that Reaſon the Peat of the Fen Lands is preferred to that of hilly Countries. When it is of a pale brown, or rediſh and ſoft, it does not burn ſo well. Sometimes there is Clay or other Earth among it, and then it is of very little Value.

It is uſed as the common Firing in Fen Countries, and burns agreeably enough: it has ſome Smell; but that is accounted wholeſome.

Peat is juſt of a contrary Nature to Manure. When the Surface of it is laid bare, nothing grows on it, except ſometimes a few Ruſhes; and when the Soil that lies over it is plowed, the Farmers take Care never to cut upon the Turf or Peat if it lie ſhallow; for they affirm from Experience, that its Mixture with the Soil renders it barren.

A ſoft ſpungy Soil, ſhaking as it is trod, with a good black Mould under the Turf, is the Mark of Peat Earth underneath. Not that it is always in ſuch Lands, but that is its uſual Situation.

It is found from a Foot to four or five under the Surface, and often the Moor or Bed of it is of conſiderable Thickneſs. It retains Wet a long Time, and therefore is ſo eaſy to cut in the Bed; for when dry it becomes hard and ſtubborn, as before obſerved.

The beſt Seaſon for cutting Peat is April and May: and the Peat muſt be cut larger than they are expected to be when dry, for they commonly ſhrink one fourth Part in the drying.

The uſual Situation of Peat is this; firſt there is a heavy thick Sod, that gives Way under the Feet; then a moiſt, black, moory Soil; of a Foot or more in Depth; then comes the Peat, which is two, three, or more Feet in Depth; and under this is a Bed of Clay.

This is the Reaſon the Peat keeps ſo moiſt in the Pit. The black light Soil lets Wet eaſily through; and it freely penetrates the Peat, but the Clay at Bottom ſtops it, ſo it ſwells, grows ſpungy, and lifts up the Soil, making it ſhake and give Way on treading.

The Graſs over the Peat Moors is uſually coarſe and harſh; and where the Peat Moor is thickeſt, there the Graſs is always worſt. Where this Moor or Bed of Peat is very thick, as it will be in ſome Places five Foot or more, they don't cut the whole, but only the upper Part; two or three Feet at fartheſt into Peat. The under Part is uſually in theſe thick Beds too moiſt for Uſe.

In ſome Places there is a Bed of Sand inſtead of a Bed of Clay under the Peat Moor; but this is not ſo common, nor is the Peat uſually ſo good where this is the Caſe, as where there is a firm Clay.

In the Fens they have two other Sorts of Fuel of the Peat Kind, but inferior in Value; the one they call Seſs, and the other Hods.

The Seſs is cut from the upper Part of the Beds of Peat. It conſiſts of a light brittle Earth, with little of the black Bitumen in it, but with the Parts of Plants in the ſame Manner as the other. The Hods are cut out of the loweſt Part of the Peat Bed; but it is not every Peat Bed that affords either. The Seſs only lies on the drier Moors; and the Hods, which ſtink in burning, come from the moiſt Bottoms of thick Beds.

This Bed of mix'd Matter, partly bituminous, and partly vegetable, which forms the Peat, has been ſuppoſed owing to the Sediments of great Floods, which have remain'd a long Time upon the low Lands; but that is not the Caſe. Bituminous Matter, like Pitch, does not ſettle from Floods: beſide the ſame Matter is found in the ſame Form impacted with Roots, and making regular Beds of Peat Earth at the Tops of Hills, and on their Sides; and theſe are Places that can never have been overflow'd.

From this I mean to encourage the Farmer, not to ſuppoſe Peat is to be found only in one Situation; but wherever he finds a Piece of Ground that ſhakes under his Feet, and is covered with coarſe Graſs, and that has a black Mould under the Sward, to dig a Foot or two, and ſee whether he do not find Peat Earth at that Depth.

It is a Fuel very well worth uſing wherever it can be had, it heats Ovens better than any other: it is cheaper than any, and its Aſhes are valuable as Manure, though in its natural State it is of all Things the moſt an Enemy to Fertility.

One ſingular Uſe of Peat is the keeping on Fire a great while; a Piece of it lighted at one End, and dipped in Water at the other, will keep fire all Day.

It is excellent for many of the nicer Chymical Operations, and if it were to be had univerſally, would be called for more than is imagined. I would therefore have him who can dig it, not be negligent becauſe it is not known or commonly us'd about the Place. Let him dig and dry it, and he will ſoon find Buyers.

What may tempt the Owner of Land to ſearch for this valuable Commodity more generally than is done at preſent, is, That I can aſſure him from my own Experience, that other Places beſide Hills and Fens afford it. I have ſeen it cut through in many Meadows, when they were only diging the Trenches to drain them; and no-body regarded it. At Mears Ashby in Northamptonshire, and at Grafton Underwood in the ſame County, they dig excellent Peat, though quite out of the Fens, and far enough from the Hills: it lies at about fifteen Inches under the Sward, with a rich black Mould between; and runs to a great Depth. The only Mark of its being in theſe Paſtures, is a little Unfirmneſs of the Ground, and this may lead the Owner of Land to ſeek for it in many Places, where the Situation does not naturally, at leaſt according to the common Opinion, make it expected.

At the ſame Time that I recommend the Search of the right Peat in Places where it has not before been found, it is proper I caution the Undertaker againſt uſing his Labour upon a wrong Sort, which has been lately tried in ſome Places. I don't know whether it was from Ignorance of what Peat truly is, or from a Suppoſition that Turf, or the outer Covering of boggy Land would do as well: but Thomas Renolls my Neighbour cut the upper Turf of a boggy Ground into long ſquare Pieces like Peat, and dry'd them for burning. He told me, when I repreſented the Folly of this Project, that a Relation of his had done the ſame ſucceſsfully.

Whether his Relation told him what was falſe, or he did not underſtand him, I cannot ſay, but the Event was what might be expected: the Turf was light and fuzzy, and did not burn well, nor was worth any Thing. It was much like the Seſs already deſcribed, only worſe. Theſe wet Places are always cover'd with a Turf that is very full of Roots, but there is none of the bituminous Matter. So that this is not Peat, but quite another Thing: neither was there upon Trial found any Peat Earth at the Bottom of this Bog.

It is proper I here warn the Perſon who ſhall find Peat on his Land of another Error. It is commonly ſuppoſed the Peat Earth grows: but this is a Miſtake. When he has once cut up the Quantity any Place yields, he muſt not expect any more for ever.

In Lincolnshire where they dig great Quantities, when they have cleared one Dike as they call it, they open another: and they throw into the firſt the Turf and Mould out of the other. It is pretended this will yield more Peat in twenty Years, but I have ſeen it try'd after twenty five or thirty Years, according to good Authority, and without the leaſt Succeſs; when the Peat Bed is once dug up it never is renewed.

The curing of Peat is a Thing of no great Difficulty, they are cut in the firſt Summer Months in the Shape of large Bricks, and are laid ſingly upon the Earth to dry. They are very ſoft when firſt dug, but they ſoon loſe Part of their Moiſture, and harden in Proportion. They are to be turn'd twice or three Times while they lie ſingle, and after they have thus got a tolerable firſt Drying, they are to be piled up in Heaps like a Wheelwright's Felleys, with Spaces for the Air to blow in between: in this Manner they get thoroughly dry, and are fitted for the Fire.

The Huſbandman muſt keep in Mind the Difference between Peat, and the common Turf of the Ground, not only for Fuel, but as uſed for Manure: for as the Peat is much ſuperior to any Kind of upper Turf for Firing, ſo on the other hand, the upper Turf of moory Ground is better for burning to Aſhes for Manure than Peat.

End of the Appendix to the First Book.

A COMPLEAT BODY OF HUSBANDRY.

The INTRODUCTION.

Of Manures in general.

AFTER a thorough Conſideration of the Soil, both with reſpect to its Cultivation and other Uſes; it is proper we lead the Farmer to the Underſtanding of Manures, by which the Improvements of Cultivation are in a great Meaſure brought about: the breaking the Land by the Plow, and the altering and enriching it by theſe Dreſſings, being the two Articles on which all the Amendment of a Soil depends.

The Buſineſs of the ſucceeding Book is to treat of Manures; and that not ſlightly or imperfectly. Care ſhall be taken to draw together the whole Number of theſe; to arrange them naturally, and preſent them one by one before the Eye of him who is to uſe them.

Nor ſhall we be content with informing him of the Effect each has upon that Kind of Land to which it is ſuited; but he ſhall know how it acts: informing his Judgment, inſtead of truſting all to his Memory.

This is our Deſign in the preſent Part of the Work: we are ſenſible that the Undertaking is large, as well as difficult; but we have been favoured with ſo many Communications upon the Subject, that we hope in ſome Degree, to proportion the Execution to the Deſign.

In treating on the ſeveral Manures, many muſt be call'd up again which have been nam'd already; but we hope the Caution that has been uſed in methodizing the Papers, will prevent tedious or needleſs Repetitions.

In the Arrangement of theſe ſeveral Articles, we ſhall firſt make a general Diviſion into the natural and artificial Manures: among which, the Uſe now made of ſome of the natural Kinds would have appear'd as ſtrange to an earlier Practitioner in Huſbandry, as the Invention of many of the others.

In treating of the Uſes of the ſeveral Kinds, and their proper Application, we ſhall throw aſide Theory and Conjecture, building all upon Experience. If the Farmer be not perfectly inſtructed as to the particular Kinds of Lands which demand particular Dreſſings, it would have been better for him if thoſe Manures had never been invented.

A Soil may be render'd worſe than it naturally is by bad Management; as certainly as it may be improved by good: but as we ſhall inſert nothing here but what is ſupported by repeated Experience, we wiſh the Farmer to prove ſo much his own Friend, as to give what may appear ever ſo new to him, if it ſuit his Purpoſe, a fair Trial.

BOOK II. PART I.

Of NATURAL MANURES.

CHAP. I.

Of the Nature of Marle.

IN treating of the natural Manures, 'tis fit we begin with the moſt conſiderable, which is Marle. It is indeed in all Reſpects ſuperior to the Generality of the others: it ſuits many different Kinds of Lands; and its Effects in rendering them fruitful are not more ſurprizing than they are laſting.

Marle is a Treaſure to the Farmer whereſoever it is found; and there is no Country in the World where there is more of it than in ENGLAND: yet there are few Places in which it is known to lie. The Induſtry of thoſe who deal in Huſbandry has not been in any Thing ſo ſlack, as in the ſearching after this valuable Commodity.

We ſhall endeavour to awaken them to a Senſe of their Intereſt, by ſhewing its Value: and to aſſiſt them in the Search after it we ſhall endeavour to make it known to them by Sight and Feeling in its ſeveral Appearances, for theſe differ greatly. After this, to prevent Miſtakes in the Application, the ſeveral Kinds of Marle ſhall be diſtinguiſh'd, and the particular Kind of Land ſhewn, to which each properly belongs.

In looking into what has been formerly known concerning the Marles, one is ſhocked to ſee that Huſbandry has declined in this material Reſpect in ENGLAND. Our Anceſtors two thouſand Years ago were well acquainted with their Poſſeſſion of this Treaſure, and its Uſe. The old Latin Writers celebrate the Marles of ENGLAND, and tell us that the Lands were greatly enriched by them. They enumerate ſeveral Kinds: and ſeem much better acquainted with their Nature and Qualities, than the Generality of our preſent Farmers.

We ſee what Treaſures Marle Pits at this Time prove where they are open'd, and what Advantage the Land has from that Dreſſing. Let us endeavour to find them in more Places, and make that Benefit univerſal.

In order to the Huſbandman's finding Marles upon his Land, he muſt firſt have ſome Knowledge of them. The very fineſt Kinds have often been thrown up accidentally in digging on other Occaſions, and no one has known them. The Fields have languiſhed for want of what they contain'd in their own Bowels thro' the Ignorance of their Owner.

Marle is of ſeveral Kinds, and differs greatly in Appearance; but to him who will carry a general Knowledge of it in his Head, it may be always known in whatever Form.

Marle, like other Earths, may be pure or foul: for thoſe Beds of Matter which lie in the Earth are ſubject to Mixtures as well as thoſe on the Surface, tho' not ſo frequently: and the deeper Marle lies, uſually the purer it is.

We ſhall firſt then divide the Marles into two Kinds, the pure and the mixt. The pure Marles all agree in their Texture; their Difference being only in the Degree of Hardneſs, and in the Colour.

Pure Marle is a Subſtance not unlike Fullers Earth. It is ſoft and fatty to the Touch; it is not tough like Clay, nor duſty like Ochre, nor ſandy like Loam, but it is of a tender fine Nature, unlike all other Sorts of Earths.

When a Farmer finds a Piece of Earth of this Kind, whether it be thrown up in digging a Well, or by whatever other Accident, let its Colour be what it will, he may depend upon it 'tis a Marle. In order to be more confirm'd, let him throw a Piece of it into a Baſon of Water, and he will find it ſwell like Fullers Earth, and crumble in the ſame Manner of it-

ſelf

ſelf to Pieces. This is a certain Confirmation. The harder and more compact Kinds break ſlower, the ſoft and looſe ones quicker: ſome almoſt immediately. But in whatever Manner it happens, this, joined to the others, is a ſure Proof that the Earth under Examination is a Marle: and let him who has fallen by Chance upon a Piece of it, dig in Search of the Treaſure.

CHAP. II.

Of the ſeveral Kinds of pure or unmixed Marles.

OF theſe pure Marles there are four principal Kinds, diſtinguiſhed according to their Colours.

A white, A red,
A yellow, A blue;

there is alſo a black, but it is leſs common.

Theſe are to be diſtinguiſhed under the Name of pure Marles of thoſe Colours; for there are of the foul and coarſer Kinds of the ſame Colours.

I have Experience on my Side in ſaying, that theſe excellent Marles are all more common than is ſuppoſed. I have ſeen the blue Marle thrown up in Buckinghamshire, and the red in Abundance in Warwickshire, as fine as the beſt in Sussex or Kent. And not very many Years ſince in Worcestershire, as much white Marle was diſcovered among the Rubbiſh where they were ſinking after Salt Springs, as returned a great Part of the Expence.

In ſhort, though there are but a few Counties in which Marle has been found, and is in Uſe in England, I believe there are very few where it may not be diſcovered; nor is any Thing ſo well worth the Search.

There are found in different Places Marles of theſe ſeveral Colours, varying in their Texture and Hardneſs; but, in general, the white or whitiſh are the ſofteſt and lighteſt, and the blue are the firmeſt and heavieſt.

For this Reaſon the white is generally uſed for Paſture Grounds, and the blue for Corn Lands. This is the general Practice in Kent and Sussex, where the Marles are moſt frequent, and their Uſe is beſt underſtood; the white being there almoſt univerſally of a looſe crumbly Texture, and the blue of a more compact and firm.

This Cuſtom, however, is not to be eſtabliſhed into a Law to the Farmer. Though in thoſe Counties where they have Choice, they uſe the ſofteſt Marles for Paſtures, becauſe they diſſolve the moſt freely; and the harder for plowed Lands, where they are more aſſiſted by Tillage. The Farmer, who has either of theſe Kinds, may uſe it indifferently on both Occaſions, in this Manner.

If it be the blue firm Kind, or any other of the compact Sorts, let him lay it upon his Corn Land early in the Seaſon, that the Weather may mellow it before the laſt Plowing: if it be for Paſture Ground, let him in the ſame manner lay it on in Time, ſpreading it thin. If it be the white, or any other of the looſe and crumbly Kinds, it need not be laid on either till late, becauſe it breaks and diſſolves almoſt as ſoon as it is expoſed to the Weather.

The Colour of Marle is no certain Proof of its compact, or crumbly Nature; but, in general, the blue is firmeſt, the white ſofteſt, and the red and yellow are of a middle Degree between both.

At Blunds-Court, and in the Pariſh of Shiplake, both in Oxfordshire, there is dug a whitiſh Marle, of the fine crumbly Kind. It is uſed both on Corn Lands and Paſture Grounds with great Succeſs; and they lay it on at any Time of the Year they pleaſe, for it melts into the Earth like Cream, almoſt as ſoon as it is ſpread.

In ſeveral Places in Warwickshire I have ſeen a blue Marle, the ſame that is ſo much eſteemed in Sussex. This is at firſt as firm as Clay. This Kind ſhould be laid on Corn Lands at the Beginning of Winter, that it may be broke by the Froſts and Rains.

I have mentioned that the Uſe of Marle was well known in Huſbandry in this Country in the Time of the Romans. There is alſo plain Proof that it has been uſed long ſince that alſo in many Places, where the Farmers know nothing of it now. A melancholy Proof that the Art of Huſbandry, which is ſo well worthy to be improved, has declined inſtead of advancing in the late Ages.

As an Inſtance of this Uſe of Marle in Places where though it is wanted, it is not employed at preſent, I may cite the common Report of the People of Northamptonshire. In Crickfield in that County, there are a great many old Hollows, which they at this Time call Marle Pits or Marlow Pits, and ſay were dug for Marle.

In the Lordſhip of Winwick, in the ſame County, are many other ſuch Holes, all which the Country People have heard their Fathers ſay, were dug for Marle to improve the Land: and old Deeds of Eſtates mention Marlaria, or Marle Pits, as Articles of Value upon them.

In the ſame Manner I have ſeen in almoſt all the Counties in England, for I have viſited moſt of them to encreaſe theſe Obſervations, one where or other in the Fields theſe old Delves, Pits or Hollows, they are now overgrown with Graſs; but in thoſe Counties where Marle is commonly uſed, they are always known to be old Marle Pits; and in others they have generally ſome Report of their having been dug for ſomething to manure the Land.

This Practice, which has been ſo univerſal, I would fain have univerſal again: for no Manure whatſoever is ſo advantageous. Let the Farmer mind well the Nature of his Marle, and the Nature of his Soil, to ſee they are ſuited to one another; and if his firſt Trial do not ſucceed, let him not be diſheartened at that, but go on: he will not fail of Succeſs at laſt.

They uſe Marles in many Parts of Buckinghamshire as frequently as Dung in others; and yet in ſome Parts of the ſame County the Farmers ſeem not to know there is any ſuch Subſtance in being. I was the Occaſion of a Far-

mer's

mer's trying a red Marle, found there very near the Surface of the Earth, in digging a Ditch for a Fence. It was one of the pure Kinds, and as ſoft as Fullers Earth in the Hands: and it crumbled in the ſame Manner in Water, and crackled on being put in the Fire. I ſhewed him by theſe and other Marks, that it was a right Marle; but whether he laid it on a wrong Soil, or in whatever unſkilful Manner he managed it, when I next ſaw him, he reproached me for adviſing him to uſe it, and declared he would never try any Projects again. So difficult is it often to get theſe People to make any Attempt; ſo next to impoſſible to make them perſevere.

CHAP. III.

Of the ſeveral Kinds of impure or mixed Marles.

THOSE already named are the richeſt and fineſt of the Marles: and as all Mixture debaſes their Value, among the other Kinds which I ſhall diſtinguiſh by the Name of impure or mixed Marles, the moſt impure are conſtantly of the leaſt Value. Theſe mixed Marles differ not only in Colour, but in their very Nature, according to the Subſtances which have got in among them. Their Colour is no general Mark of Diſtinction, but they may be very well arranged under ſeparate Heads, according to the Subſtances of which they partake. Theſe being Sand, Clay, Loam, or Stone, they may be conſider'd as

Sandy Marles, Loamy Marles, and
Clayey Marles, Stony Marles:

And among theſe laſt are alſo to be comprehended ſome which have at firſt the Hardneſs of a Stone from their own Nature and Compoſition, though they have not a Particle of real Stone in them.

Many Marles alſo, beſide theſe natural Earths and ſtony Matter, contain great Quantities of Sea Shells, which are preſerved in them in a ſingular Manner; for inſtead of being petrify'd, or render'd hard, they are made brittle, and ſeem as if they had been calcined. Theſe Shells are far from injuring the Marle in its improving Quality; they, on the contrary, are found to encreaſe that Virtue.

There are of theſe ſeveral Kinds of Marles of all the beforementioned Colours, but greyiſh or yellowiſh are the moſt frequent. The ſandy Kinds are the richeſt of theſe impures ones; and they are fitteſt for ready Uſe, for they break to Pieces in the Hands eaſier than any others; and the ſooneſt of any crumble with the Weather. In a proper Application theſe may be accounted of equal Value with any, for on clayey Lands the very Sand which is contained in them is uſeful.

The loamy Marles are the next in Value among theſe to the ſandy, for they break eaſily with the Weather; but in theſe as the former, a great deal of the Advantage ariſing from the Uſe of them, will depend upon a proper Knowledge of their Nature, and their Uſe on a right Soil.

The clayey and ſtony are inferior to the others: but on ſome Lands the former are preferable to thoſe which are more pure: and amongſt the ſtony Kinds there are ſome, and they even of the hardeſt; which, when properly mellowed by the Weather, are inferior to none in Richneſs. I have ſeen ſome of theſe that a large Hammer would make no Impreſſion upon when firſt dug up; but that with Froſt, Rain, and Sunſhine, have in ſix Months Time crumbled away to Powder.

Some of theſe I have ſeen which when broke with great Labour, and laid upon the Lands, have for ſeveral Months appeared like ſo many Stones ſcattered over the Fields, and ſeemed to damage rather than improve them: but after one Winter there has not been a Piece of any one of the Lumps ſo big as a Nutmeg to be found; and the Land has been kept in Heart eight or ten Years by that ſingle Dreſſing.

One Farmer I knew in Warwickshire (where they know the Nature and Uſe of Marles better than in any County in England, after Kent and Sussex) who having a ſtony Marle upon his Ground, dug it at a good Expence, while all his Neighbours laugh'd at him; and after it had been expoſed to the Air and Rain in his Yard till it began to crack and break, laid it on his Corn Lands, and had it broke there with Hammers: after this it ſoon melted and enriched the Land to a degree beyond Belief.

I name this Practice that the Farmer who has a Marle ever ſo hard and ſtony, need not for that Reaſon give it up as uſeleſs.

They have in many Parts of Northamptonshire a ſtony Loam which the common People call Penny Earth; it is full of Sea Shells, ſome of which are flat, and reſemble Pieces of Money, whence it has its Name. This is as hard as Rock when firſt dug, but it moulders of itſelf with the Weather, and even the Shells that are in it diſſolve, ſo that not one of them is to be found on the Lands where it was laid. They uſe it ſome Places, but not nearly ſo much as it deſerves; when it is kept dry, it retains its Hardneſs for ever.

Marle in ſome Places is to be dug for at a conſiderable Depth, and even this is well worth while: but more frequently it lies near the Surface; ſometimes ſo near, that they plow up a part of it with the Soil; and the ſame Thing turns and manures it, and that very profitably.

In Kent the Marle ſometimes lies deep; but in Sussex it moſt frequently is within a Foot or two of the Surface, with a tough Clay over it; this anſwers a very convenient Purpoſe; for it holds the Marle ſo well together above, that by undermining it they can have a fall of a hundred Loads or more at a Time, ſo that the Expence is hardly any thing.

CHAP. IV.

Of certain Marles found in particular Counties.

IN Buckinghamshire I have obſerved a very rich Marle of the purer Kind, and of a mixed Nature between the blue and red; the red make-

king the Body of the Mafs, and the blue being difpofed in Streaks and Veins. This is one of the fatteft Kinds, as the Farmer terms it; and is the fame that is fo much eſteem'd in KENT for fandy Land.

In WARWICKSHIRE they have a blue and red Marle of a ſtiffer Kind, which does not do well on Paſture Lands, but excellently on ſandy Corn Grounds.

In CHESHIRE they have a Marle of the ſtony Kind, which they call Slate Marle: they give it this Name becauſe it ſplits in the Manner of Slates into flat thin Pieces; they have this of all the common Colours, and it is much the ſame whether red, yellow, whitiſh, or blue.

They have alſo in STAFFORDSHIRE on the Borders of CHESHIRE, a Kind of ſtony Marle, which always breaks in a Kind of ſquare Pieces; this they call for that Reaſon Dice Marle. It is uſually yellowiſh, rarely rediſh or blueiſh. Both theſe Kinds, though ſtony at firſt, mellow, ſoften, and fall to Pieces with the Sun and Rains; and they are greatly eſteem'd by the Farmers. They have in the ſame Places clayey Marles, but they find thoſe clog the Land after their enriching Effect is over; whereas theſe leave it better than it was before they were employ'd, even after their enriching Virtue is gone.

Indeed in moſt Countries they value the ſtony Marles, becauſe of their laſting Efficacy. The fatty and crumbly Kinds enrich the Ground more quickly; but it is theſe hard ones that give that Fruitfulneſs which laſts many Years; after it has ſerved the Purpoſes of the Tenant enriching the Landlord.

One Thing farther I muſt aſſert from Experience, which is, That ſome of theſe Marles of the harder Kinds, which enrich Land for ſo long a Continuance, have often a bad Effect in the End. After this long Period of Fruitfulneſs obtain'd from them is over, the Land becomes ſo barren that ſcarce any Thing can make it fruitful again.

The hard white Marle is moſt ſubject to this Cenſure, for it approaches to the Nature of Chalk, and the ſame Thing has been obſerved of Chalk to a Proverb. But I don't know that the other hard Marles are liable to this Fault.

To the ſeveral particular Kind of Marle mention'd for their Uſe in particular Places, I ſhall add three or four with the Names by which they are known, upon the Spots where they are found and uſed; and then cloſe this Chapter: in which having, I hope, thoroughly acquainted the Huſbandman what Marle is, and how numerous Kinds there are of it, I ſhall in the next proceed to the moſt advantageous Methods of uſing it.

In SHROPSHIRE, and that Part of CHESHIRE which borders on it, they have duſky browniſh blue Marle, ſtreaked and ſpotted with a cleaner blue and with white: this they call Cowſhut Marle, and the Country has received great Advantages from the Time in which it has been introduced into frequent Uſe. This is to be refer'd to the blue Marles of the purer Kinds.

In STAFFORDSHIRE there is a peculiar Kind of ſtony Marle, which they call Shale Marle there as well as in CHESHIRE, where it is alſo found in Abundance. This is of a greyiſh or aſh Colour, and ſeems a mere Sand Stone: but it breaks freely enough. They do not uſe this ſo generally as they might, but where they do, it turns to a very good Account. If the Farmer therefore finds a blueiſh grey Sand Stone in his Grounds, let him try whether it does not moulder in the Air, or crackle in the Fire, and if ſo, let him ſee to make a better Uſe of it than they do in many Places in this County, where they abſolutely throw it away.

In CHESHIRE they dig a Marle of a duſky Colour, and tough Subſtance, very unlike the Generality of the other Kinds; this they call Peat Marle. It is one of thoſe which are debas'd by an Admixture of Clay: it is not peculiar to CHESHIRE, for they have it in SHROPSHIRE alſo; but the Uſe differs. In CHESHIRE they uſe it as a Manure; and if laid on proper Land, as the ſharp ſandy Soils, it yields a good Encreaſe: in SHROPSHIRE they make Bricks of it.

They have in CHESHIRE alſo, and in STAFFORDSHIRE, and ſome other of the neighbouring Counties, a ſtiffer Kind than the laſt deſcribed. It is of a yellowiſh Colour, and from that and its Toughneſs they call it Clay Marle. This often lies in very deep Beds, but the Farmers are not ſo well acquainted with it as they might be; it is full of Sand and Pebbles in the upper Part of the Bed, where it often riſes within a Foot of the Surface, but it is pure below. This is one of the clayey Kinds, and they uſe it on the worſt Lands with very good Succeſs. Let the young Huſbandman therefore, who thinks his Land is clayey at the Bottom, in ſome particular Spots only, examine this Clay. They ſay all is not Gold that ſhines. 'Tis true Things are often worſe than they ſeem; but ſometimes they are better.

They have alſo in that County a Kind of Marle they call Paper Marle: this lies in Leaves, and is a very pure and rich Kind.

CHESHIRE is alſo remarked for another Kind of Marle, by ſome ſuppos'd to be particular to that County, they call it Steel Marle: but thoſe who will be at the Pains of examining the ſeveral Parts of the Kingdom with the ſtrict Eye that I have, will find very few Things are peculiar to the Places where they are firſt found, though thought to be produced in no other.

This Steel Marle is of a duſky Colour, often ſpotted with red, and ſometimes with blue. It is very hard; and when ſtruck with a Hammer, naturally ſhatters into a Kind of ſquare Bits. It is one of the ſtony Kinds, and is the ſame in its Nature and Subſtance with that which they call Dice Marle in NORTHAMPTONSHIRE, though it differs a little in Colour.

I have obſerv'd with Pleaſure, the Manner in which this Kind of Marle divides when laid upon the Ground. Firſt, the large Lumps lie like ſo much Lumber of which the Land ſhould be cleared: after this one ſees all the Surface of the Field ſpread over with corner'd Pieces of ſome conſiderable Bigneſs: then after a little more Effect of the Weather, it lies every where in Bits like Dice, many of them very ſmall; and after this it is blended with the

Mould, and altogether loſt. Then it is that its full Virtue and Efficacy are ſeen in the Crop.

CHAP. V.

Of ſeeking for Marle.

AS the conſiderate Huſbandman muſt ſee by what has been ſaid occaſionally already, and will ſee more fully by the ſucceeding Chapters, the vaſt Value of Marle: It is natural that he ſhould bethink himſelf of ſeeking for it on his own Grounds, I ſhall not only encourage, but aſſiſt him in the Search.

In the firſt Place he has this to tempt him to examine his Land in Hope of it, that I have obſerved already it is frequent in many Places where it is not regarded or even known: and I ſhall add, that although ſo little obſerved, it is a Commodity ſo naturally and generally the Produce of England, that I believe there are few Pieces of Land of any Extent in which one Kind or other of it may not be found.

If it be too deep indeed, it may not be worth taking up, but that is ſeldom the Caſe: it is commonly near the Surface.

The ſeveral Kinds and Varieties of it have been ſo fully deſcribed, that the Farmer has all the Reaſon in the World to ſuppoſe he ſhall know it at Sight: I ſhall add to theſe the Soils under which it uſually lies.

But prior to this, which beginning without any certain Information, is a more random Kind of Search, I would have him examine well both by Report and by the Appearance of the Ground, whether Marle has ever heretofore been dug in his Land, or any where near its Borders.

If he hear that it has, let him look narrowly after thoſe broad and ſhallow Delves in the Ground which have been before mention'd, for they are certainly the Places where the Pits were. If he can learn no ſuch Thing by Report, yet let him ſee if there be any ſuch Hollows in the Ground, for though leſs certain, ſtill they are an Evidence that ſomething has been dug. It may have been Gravel, but Marle is more likely.

When he has found any ſuch Hollows, let him mind the Courſe wherein they run, for that Way probably the Marle runs alſo.

If he find only one ſuch, let him firſt obſerve how deep it is; for on this depends the Nature of his Search, ſince by this he may gueſs whether the Marle lay low or near the Surface.

His Buſineſs is to try all about the Place where the Hollow is, for Marle. If that Hollow be very ſhallow, let him have Holes dug to the Depth of three Foot with a Spade; if deeper, let him uſe an Augur, ſuch as they bore the Ground with on various Occaſions. Let him bore in a great many Places to the Depth of ſix Foot; for if the Marle lie deeper than that, 'tis hardly worth his digging; but let him examine ſtrictly every Thing the Augur brings up within this Depth. Let him keep in his Mind the various Kinds of Marles I have deſcrib'd; and if any Thing come up that has the leaſt Appearance or Reſemblance of any of thoſe ſeveral Kinds, let him try it by ſeeing if it moulders away in a Baſon of Water, if it crackles on being put into the Fire; and what Effect the Sun and Air take upon it when it has lain two or three Nights expos'd.

By theſe Means if there ever have been Marle dug there; and the Vein of it continues, he will be ſure to find where it runs; and he is then to follow the Courſe of it by the Augur, and conſider where he can open a Pit of it the moſt conveniently for the general Uſe of his Land.

But ſuppoſe there be not the leaſt Sign upon the Ground, or the leaſt Account from Report that Marle ever was dug any where thereabouts. Yet this ſhould not diſcourage him from enquiring if there be any; for there is a Time for the Diſcovery of every Thing.

In this Caſe he muſt firſt have Recourſe to what he can ſee upon digging any where. If a Well be ſunk at any Time upon or near his Land, let him look carefully over all the Kinds of Earth that are thrown up. Nay, if a Pond be dug, let him make the ſame Obſervations.

Let him examine the Sides of Ditches new dug or cleaned; and follow the Plow with a careful Eye, obſerving if it any where turn up Matter different from the Soil. For Marle often is within the Reach of the Plow.

If he diſcover nothing of the Nature of Marle in all theſe Reſearches, let him have Recourſe to the Augur, boring in different Places, but chiefly in the clayey Soils, for under theſe the Marle oftenеſt lies.

The mellow Earth is the next Soil that is likely to conceal Marle: and after this the loamy Earth. It ſometimes lies under Gravel, but ſeldom in any great Plenty: it very rarely is found under a ſandy Soil, and then commonly in a thin Vein, and at a great Depth.

The clayey Soil not only oftenеſt has Marle under it; but that which lies under this Soil is uſually of the fineſt Kind. I have obſerv'd before, that the Kentish Marles generally are cover'd with a Foot or two of tough Clay. In general it is the fineſt, pureſt, and richeſt Marles the Farmer is to expect under this Soil.

It has been obſerv'd, the fine black mellow Earth of the low Lands, commonly has under it a Bed of tough Clay. Sometimes it has a thick Bed of ſome fine Marle, particularly of the rediſh Kind, in the Place of the Clay; and very often a Vein of Marle comes between the Clay and the Mould.

The former is the beſt for the Farmer; but if the latter preſents itſelf, let him follow with his Augur the Courſe of the Vein, and he will find it gradually thicken till at laſt it uſually takes the Place of the Clay. It is here he is to open his Marle Pit; and he will often fall upon a Bed of Marle five, ſix, or ſeven Foot thick, riſing within a Foot and half of the Surface of the Ground.

Sometimes the ſtony Marles are found under Clay or black Mould, but it is more commonly the pure, fatty, and tender Sort: as to thoſe found under ſandy Soils, they are uſually one

or other of the clayey Marles, and with double Expence in digging, are not of half the Value.

There are ſome Parts of SUSSEX where a Bed of Marle comes up within eight Inches of the Surface, and when open'd is found to be ten or twelve Foot thick, all of ſome one of the pure and fine Kinds: and in CHESHIRE, and alſo in LANCASHIRE, where the beſt Marles often lie under the fine black Mould, I have ſeen a Bed of blue Marle that was within a Yard of the Turf, cut down to four Yards deep, and they were not then got through the Vein.

When the Farmer has by the Methods already deſcrib'd, found out a Vein of Marle, and fix'd upon a convenient Part of his Land for opening of a Pit: let him begin by marking out a tolerable large Place for the Work; and for a proper Way for the Carts that are to fetch out the Marle. A great deal depends upon all this being well order'd, and now is his Time for Contrivance.

He is then to employ his Labourers to clear away with Pick-axe, Spade, and Wheel-barrow, all the Soil that covers the Vein of Marle, and when this is done, they are to begin digging it.

The different Condition of the Marle will now be found, and the neceſſary Accidents of treating it. Where it is of the fineſt and tendereſt Kinds, they often work with a Kind of Hoe, and three Hoers will tear up as much as four can fill it into the Carts.

In the clayey Kinds they uſe Spades for digging, and then the Diggers muſt be more than the Fillers. Sometimes theſe are ſo dry and tough, that the Workmen muſt have Water brought to them to wet their Spades; and in other Places they are ſo wet, that there muſt be a Pump ſet up to keep them dry.

When the Marle is got into the Cart, it is to be ſhot on the Fields; but this in a different Manner according to its Nature. If it be of the fine ſoft tender Kinds; the beſt Way is to ſpread it as it is taken out of the Cart: but if it be of the ſtony or other compact Kinds, every Load had better be ſhot ſeparately, and left in a Heap for the whole Winter, that the Froſt and Air may mellow and break it.

CHAP. VI.

Of ſuiting the Marle to the Land.

THERE are very few Lands that may not be improv'd by Marle, but ſome require it more than others: there are alſo many Kinds of Marles, as well as many different Sorts of Soils; and the Marles of one Kind are fit for certain Lands, and thoſe of other Kinds for others. A ſtrict Regard muſt be had to this, otherwiſe, as already obſerved, the Land may be ſpoiled.

In ſome Places they have a Way of laying on ſuch a Quantity of the Marle, that they may be ſaid to add a Soil rather than to improve what was there before. This is the Practice in ſome Parts of CHESHIRE, where they will lay fifteen, ſixteen, or eighteen Hundred Load of Marle upon one of their Acres; they will thus in Digging and Carriage beſtow twelve or fifteen Pounds upon marling an Acre; and then they will work it with good Management twenty or thirty Years together.

For the firſt Years they plow very ſhallow; they don't cut up more than an Inch of the Soil for fear of burying the Marle; ſo going deeper in the following Years. This is a particular Practice.

In the firſt Place, the Soil which requires Marle moſt of all, and which is the moſt improv'd by it, is the ſandy. The Advantage ariſing from this Practice upon ſuch Lands, is beyond the Belief of any who have not ſeen the Fact.

The Marle which is fit for this Land is the clayey Kind, and more than all others that browniſh or yelloviſh Marle, which looks like real Clay in the Pit, but is found of ſo different a Nature when examin'd. This Marle, or any one of the clayey Kind, laid thick upon a ſandy Soil, gives it at once a Body and a Richneſs. The Clay that is in it binding the light Soil tolerably together, at the ſame Time that the fatty and enriching Earth blends itſelf with the whole.

This is the Application of Marle, in which its Virtue is moſt fully ſeen: for by this Means Land, that before would yield ſcarce any thing, has been known to produce ſurprizing Crops; nay, it has been try'd by way of Experiment, to marle one half of a Piece of new broke-up Ground of this ſandy Kind, and leave the other in its natural Condition; then both being ſown with the ſame Seed, the marled Part has yielded a plentiful Crop, when the other has not ripen'd one Ear.

Another great Advantage of this Practice is, that in Years wherein other Crops fail, thoſe ſucceed which are on theſe Grounds even to Admiration. Thus when there comes a dropping Summer, while a Piece of marled ſandy Soil is in its full Vigour, the Encreaſe is prodigious. Theſe Seaſons generally hurt the Crop on other Lands; but they load theſe with as much as can ſtand upon the Ground.

But all this Time Care muſt be taken that the Marle be well ſuited to the Soil; and this to be done by this Rule; the more ſandy the Ground is, the more clayey the Marle muſt be.

If a raſh young Huſbandman hearing of the great Profit that ariſes from laying Marle on ſandy Soils, ſhould without any farther Thought lay on one of the pure fat and tender Marles before deſcribed upon a very barren ſandy Piece of Ground, tho' he put on a CHESHIRE Loading, yet the Wet would waſh it in, and the Sand would ſwallow it up in ſuch a Manner, that the whole Effect would be loſt after all the Labour and Expence.

Next after the ſandy, the Soil which receives moſt Advantage from Marle is the Loamy; and this admits the greateſt Improvement of all when the Sand in its Compoſition bears an over Proportion to the Clay. I have ſeen Lands, the Soil of which was fitter to make Bricks than to yield Corn, ſo improved by Marle, that the Corn has ſtood like a Sward of Graſs at its firſt Appearance; and has throve ſo afterwards, that every Stalk has come to a due Maturity.

The

The Marle for this Kind of Land muſt be the pureſt and fineſt that can be had. If the Farmer ſhould lay on a clayey, or a ſandy Marle, he would only encreaſe the Proportion of one or other Ingredient of the natural Land which already made it barren.

All that renders a loamy Earth at all fruitful in its natural State, is the Quantity of Mould that is mixed in it; now a fine Marle is of the Nature of that Mould, only much richer: it blends among the Loam, and the Firmneſs of the loamy Soil holds it till it have yielded all its Virtue.

I have found from Experience, that of all the Kinds of Marle, that which agrees beſt with a loamy Soil, is the blue, pure and tender Marle. After this the beſt is the yellow: but any Marle that is light and free from Mixture will anſwer the Purpoſe.

I have ſeen the ſtony Marles tried in ſome Counties upon their loamy Soils with tolerable good Succeſs. Particularly in Staffordshire, I have ſeen that Sort they call ſhale Marle, which has been deſcribed in its Place, laid on a tough loamy Soil, abounding naturally too much with Clay.

This has ſucceeded but poorly at firſt. The firſt Year ſcarce at all, the ſecond ſomewhat better, and the third and fourth beſt of all. But as I have had Opportunities of making the Computation fairly in both Kinds, I find the pure Marle is very much preferable for this Soil to the ſtony. The Farmer may do well to uſe any of the ſtony Kinds when he cannot get the other Sort in the Neighbourhood, and he will reap conſiderable Advantage from it; but when he can have his Choice, the pure Marle is preferable for this Land by many Degrees.

I have alſo ſeen ſome of theſe ſtony Marles, not of the hardeſt Kind, uſed on ſandy Soils, but without any great Succeſs. I once indeed ſaw a ſtony Marle that had lain a Seaſon expoſed to the Air, ſpread upon a Field; the Soil of which tho' ſandy, had ſome natural Richneſs, and it ſucceeded tolerably; but ſuch particular Practices are not to be eſtabliſhed into Rules.

The Practice of marling Lands is founded upon Reaſon; and that, as well as Experience, will ſhew in what Manner it ſhould be done. The pure Marles are all fatty; the mixed Kinds are either clayey, ſandy, loamy, or ſtony; now upon conſidering this the Application is eaſy.

Let us ſuppoſe a conſiderable Farmer to have Pits of all theſe Kinds of Marle upon his own Ground; and to have a ſandy Soil as firſt mentioned to improve: he will naturally aſk himſelf which of all theſe I ſhall uſe? If I lay on pure Marle, the Rain will waſh it to Pieces, and the Sand will ſuck it up and remain as barren as ever. I may lay that pure Marle upon Soils in which there is ſomething to hold it, but never upon Sand: well then, all the pure Kinds are unfit. Now the Choice is among the others: Shall I lay on a ſandy Marle? No: for the Sand will mix with the Sand, and the Marle will be waſhed away as before. I ſhall only add Sand to Sand with all my Labour? Shall I lay on ſtony Marle? No: Stone and Sand are but a poor Mixture, and when it breaks, it will waſh away as the other. Shall I uſe a loamy Marle? why, the Clay that is in Loam will do ſome good, becauſe it will hold the Fatneſs; but then the Sand in it is again adding Sand to Sand: well then, there remains the clayey Marle, and this is fitteſt of all, becauſe the Clay will bind the Sand, while the fat marly Part enriches it: I ſhall alter my Sand into a Loam, at the ſame Time that I enrich it by the Marle.

Thus Reaſon would adviſe in the Choice of Marles, and Experience ſhews, that it is exactly the Practice which is the moſt profitable.

After ſandy and loamy Soils, that which receives moſt Advantage from Marle, is mellow Earth: this wants Improvement leſs than any other Kind, but the proper Uſe of Marle adds to its Fertility; and there is this farther Advantage, that ſcarce any Kind of Marle whatſoever but may be uſed to it: but ſtill there are ſome from which it has more Benefit than others.

Plowed Land, Meadow, and Paſture, when they have this mellow Earth for their Soil, equally receive good from Marle. As to the Graſs Lands, only the pure Marles ſhould be uſed to them, becauſe they waſh in readily, and don't lie about in Clots or Lumps upon the Ground. For plowed Lands of this Soil, any of all the Kinds of Marle may be uſed with Benefit. If they be of the clayey Sort, they break in with plowing after a little Time; if loamy, they blend ſo much the ſooner; if they be of the ſtony Kind, it takes Time for the Weather to divide them, but they do very well at laſt; and finally, if they be of the pure or of the ſandy Kind, they break with the firſt Dreſſing, and waſh in with the Rains immediately.

All the Farmer has to regard in this Caſe is, whether his mellow Soil approach in any degree to the Nature of any of the others, for there are in Nature a Variety of Degrees; and then he is to ſuit his Marle according to the particular Directions given in this Chapter, to the Nature of the Soil whereof it moſt partakes.

As to chalkey Soils, Marle is not the Manure moſt ſuited to them of all others, becauſe Marle is itſelf in ſome Degree of a chalkey Nature: nevertheleſs it is to be uſed with Prudence to good Purpoſe.

I have known Farmers who never would permit a Scrap of Marle to be laid on their chalkey Grounds, though they uſed it to the others, and ſaw the Benefit. They called this laying Chalk upon Chalk, and laughed thoſe to ſcorn who adviſed them to uſe it: but I ſhall mention what I have ſeen againſt all the Arguments in the World.

Indeed the brittle white Marle of ſome Counties is in its own Nature ſo like Chalk, that I would by no Means adviſe uſing it on chalkey Lands, though on others it may ſerve as a Manure in the Manner of Chalk, which is known to be an excellent one itſelf. The Difference between Chalk uſed as a Manure, and this chalkey Marle, for it may well be called ſo, is, that the Effect of the Marle is more ſpeedy than that of the Chalk; and that it does not wear out the Land ſo very much as Chalk does, which in the End leaves it more barren than at firſt.

Now,

Now, though for the Reaſons already given, I do not think it adviſeable to lay the white Marle on a chalkey Soil, yet I have ſeen the rich and pure red Marle, and in ſome other Places the blue Kind, uſed with great Profit. Nor is this at all contrary to Reaſon, for Chalk is one of the drieſt of Soils, and theſe pure Kinds of Marle are the fatteſt of all Manures. What then can be more proper than they to correct the Dryneſs of the Chalk.

I would therefore adviſe the Farmer who has a chalkey Soil, not to be afraid of marling it; only as in other Caſes let him ſuit the Marle to it. The blue and red pure Marles are beſt: after theſe the pure yellow Marle, or the black if that can be had. And in caſe of a Defect of all theſe, he may uſe the loamy, or the clayey Marles, but theſe are fitter as they are richer of the Marle.

Gravelly Soils have the ſame Advantage from Marle as the ſandy, and one Reaſon of this is, that they always have Sand among the Gravel. Theſe let all other Manures be waſh'd through them by the firſt Rains, but the Marles of a proper Kind remain in them. They not only enrich thoſe Lands by their own Mellowneſs, but they give them a Firmneſs that will make them hold other Dreſſings. Dung laid on a looſe gravelly Soil is loſt and ſwallow'd up without any Benefit, but Dung upon ſuch a Land that has firſt been dreſſed with Marle, takes the ſame Effect as upon other Soils.

In this, as in all the other Inſtances, Care muſt be taken to ſuit the Marle to the Soil; if a pure Marle were uſed, it would be waſhed through quicker than Dung; and if a ſandy Marle were choſen, the marley Part of that Mixture would be waſh'd down through the Soil, and only the Sand that was among it would remain. This could be no Improvement to a Soil already too ſandy.

The proper Marle for a gravelly Soil is the clayey Sort. This is the only Kind that is proper; and this never fails of giving the greateſt Advantage.

Laſt of all I come to ſpeak of the clayey Soils, which are in general ſuppoſed to be improper for marling to a Proverb. Every common Farmer can repeat what is retailed from one to another through all the common Writers on Huſbandry, and can tell his Son,

He that marles Clay,
Throws all away.

And this he thinks he has two ſubſtantial Reaſons for believing to be true, becauſe it is Verſe; and becauſe it is in print. But let not the reaſonable Huſbandman be frighted out of his Profits by Rhymes. I ſhall inform him that Reaſon is on the contrary Side, and ſhall add from what I have ſeen and known, that Reaſon is ſupported by Experience, in this as in all other Things.

It may be poſſible enough to throw away Coſt and Labour by laying an improper Sort of Marle upon a clayey Ground; and the ſame may be as truly ſaid of any other. But the Buſineſs of the preſent Enquiry is the ſuiting the Marle to the Land; and when that is obſerv'd, the ſame Benefit will follow from the Uſe of it on theſe, as on all other Soils. I have ſaid before, that all Soils are capable of Improvement by Marle, and it is becauſe there are Marles of very different Kinds, ſome of which are ſuited to every Condition of the Soil. He that ſhould lay a clayey Marle upon a clayey Soil, would have but little Advantage, becauſe it would be in a great Meaſure adding Clay to Clay: and perhaps the Farmers who firſt try'd to marle clayey Grounds, had no other than clayey Marles; and thinking all others like them, ſpoke that in general which was only true in particular.

Excepting the clayey Marles, there is no Kind of them but is good on Clay Grounds. In the firſt Place, all the pure Marles being well worked in by the Plow, blend with the Soil, and looſen and enrich it. The ſtony Kinds are kept on or near the Surface till they mellow and break, and the Firmneſs of the Ground takes in all their Benefit: the loamy Marles, if there be too much Clay in them, are to be rejected as approaching to the Nature of the clayey Kind, but if otherwiſe, they are excellent, as they approach to the Nature of the ſandy ones. Theſe laſt mention'd are for clayey Soils the beſt of all, for they conſiſt only of a fine fatty Marle and Sand, and they act doubly upon the Clay, at once looſening and enriching it. As ſoon as they are laid on, they break and crumble to Pieces, for the ſandy Marles are the brittleſt of all the Kinds, and thus ſeparated the Sand, gets into the Clay, and makes Way for the Marle, which the Rains waſh thoroughly in, and which is then detain'd among it to exert the full Effect of its Fertility.

He therefore that has a clayey Soil to manure, and can get at a ſandy Marle, has it in his Power to raiſe his Land to many Times its original Value. If a due Quantity be laid on, though not ſuch a Load as the CHESHIRE People uſe, the Sand in the Mixture converts the Clay into a Loam; and it becomes as it were another Soil, enriched with a mellow and fine Manure.

If the Farmer cannot get at a ſandy Marle, he may uſe any of the other Kinds excepting only the clayey, as has been ſaid before.

CHAP. VII.

Of the Manner of uſing Marle.

HAVING taught the practical Farmer to know Marle when he ſees it, how to ſeek for it on his own Grounds, and in what Manner to ſuit the Kind to the Nature of the Land; it remains to inſtruct him in the Manner of uſing it. For this is no little Article, and in this the Experience of others only can be his Guide, comparing their Succeſs one with another: for I am ſorry to ſay, not only the Practice of a particular County may many Times miſlead him; but what has been written under the Appearance of Advice is too often falſe.

As to the Quantity that he ſhall lay upon his Land, I have ſeen ſo many Errors on both Sides, that the Truth ſeems hard to hit. Some of the STAFFORDSHIRE Farmers lay on ſo little, that

that it ſcarce anſwers any Purpoſe. I have known theſe contented to uſe twenty Loads to an Acre, and then they have complained that what was written of the Profit by Marle was not true. In Cheshire, on the contrary, they bury their Land under ſuch Loads, as has been ſaid already, that they ſeem to ſow their Marle and not their Ground.

The Medium between theſe Practices is the right Method; and he who wou'd reap all thoſe Advantages that have been declar'd of Marle, muſt follow that Courſe. The right Uſe of Marle is not to put it in the Place of the Soil, but to make a Mixture of it with the Soil, ſo as to raiſe a poor Land into the Condition of one naturally rich: to do this, a due Quantity of the Marle muſt be employ'd; and to give a general Rule, that ſhould be about a hundred Loads to an Acre.

The beſt Way of ſowing marled Land is under Furrow, this I have ſeen prov'd by many Experiences.

The Farmer is not to look for the full Effect of this the firſt Year, but it will laſt as before obſerved: and the Continuance will be according to the Nature of the Soil, and the Kind of the Marle, ſeven, ten, twenty, or even thirty Years.

When the Farmer ſees his Land that has been marled after fair Weather look all over white, as if covered with a Hoar Froſt, he may conclude it will anſwer his beſt Expectations. It is a Proof that the Marle was good in itſelf, that it has been uſed in due Quantity, and that it is well mix'd with the Land.

Some have deliver'd this white Appearance as a Mark that there is Marle in any Part of the Land where it is ſeen; but Marle cannot diſcover itſelf in that manner in its natural Beds, unleſs they lie almoſt cloſe to the Surface. It is therefore of little Uſe in that Reſpect, but on the Lands where it has been laid, when there is this Appearance, 'tis certain that it is mix'd and mellow'd in the Ground.

I have ſhewn to what particular Lands the different Sorts of Marle are requir'd. If the hard and ſtony Kinds are uſed, they muſt be laid on early in the Seaſon: if the Clayey a little later, the Loamy may be a little later yet than the Clay: the pure Marles of all Kinds, and the ſandy Marles, are to be laid on very late. In this the Farmer's Diſcretion will direct him after theſe general Rules. The proper timing of the laying on this Dreſſing regards its Effect for the enſuing Year; but the harder Kinds with the beſt Management will not do much ſo ſoon.

The Method already nam'd of piling the ſtony Kinds in Heaps, that they may break before they are laid on the Land, is uſeful. Some ſprinkle the Marle, in theſe Heaps, from Time to Time, to aſſiſt this Breaking: and in ſome Counties they calcine not only theſe harder Marles, but any Kind they have into Lime, in Kilns made for that Purpoſe. They all burn eaſily, but they make a weak Kind of Lime. I have ſeen this try'd with great Advantage on ſome very indifferent Lands: the Quantity to be uſed of the burnt Marle is about fifty Load to an Acre.

This burning of Marles, tho' it ſucceed well enough, is altogether altering their Quality. It is fitteſt for the harder Kinds, but I ſhould prefer the Uſe of the Natural Marle, from what I have ſeen, far before it.

The laſt Method of laying on the Marle is, to ſhoot the ſeveral Loads as they are brought out of the Pit, at about equal Diſtances one from another; and then to ſpread them all. This will occaſion the Ground to be all cover'd with the ſame Thickneſs. When it is thus ſpread, it muſt be well mix'd with the Soil, and all laid ſmooth and level together: and the quicker this is done from the Time that the Marle be taken out of the Bed, provided it be a pure or a ſandy Marle, the better; for as theſe crumble to Pieces almoſt directly, the Buſineſs is to get them mix'd in the Ground at once, that they may begin to break among it, and ſo perfectly make one Body of the whole; for this is the true Nature of an Improvement by Marle.

A clayey Marle ſhould never be laid on in the Beginning of Winter, for it ſometimes, inſtead of breaking, grows tough with repeated wetting, and the Land that ſhould have been improved, is render'd worſe by it.

This is one of thoſe Accidents that have made the Farmers in ſome Places declare againſt Marle when they had try'd it. Accidents are poſſible to all Things, they uſually happen thro' Ignorance; but ſometimes the Seaſons occaſion them, the prudent Farmer is to inform himſelf how they may be cured.

In caſe of the Marles binding in this Manner, he muſt ſtrew over it a ſmall Quantity of Marle Lime, or of other Lime mix'd with well rotted Dung; this will immediately break it: and not only that, but the Land will be ſo much the more enriched by this double Dreſſing, that the Largeneſs of the Crop will leave him no Room to complain of his double Expence: it will be doubled in Proportion. This I have ſeen try'd, and I have been ſurpriz'd at the Produce. Thus Accidents when rightly manag'd may prove Advantages.

If the Field to be marled lie level, the Marle is to be ſpread evenly over it, not thicker in one Place than another: but if it lie upon the Deſcent, the beſt Way is to ſpread the Marle half as thick again on the higher Part of the Field as on the lower, for the Rains will waſh enough of its beſt Part down to make all equal. I have ſeen where a Field has lain greatly on the Deſcent, and this Management has not been uſed, the Crop vaſtly thicker on the lower Part than on the upper; and on examining the Soil, it has appeared quite different in the upper and lower Part; not only a great deal of the Richneſs of the Marle, but of the fineſt Part of the Soil itſelf being waſh'd down.

Theſe are Accidents on which the prudent Farmer ſhould always have a watchful Eye; for he may prevent their Inconveniencies by right Management.

Burnt Marle, or as it is rightly enough called Marle Lime, can never be needful where pure Marle has been uſed, although it may after the tough clayey or other mixed Kinds; for inſtead of binding, the pure Kinds moulder away

away either while they are wet, or in the drying.

The Nature of the Soil is to be conſider'd for the Time of laying on the Marle, as well as the Nature of the Marle itſelf. If it be a hard binding Ground, the beſt Time of laying on the Marle is the Beginning of Winter; if a light looſe Soil, the Spring or Summer: always accommodating this however to the other Conſideration, the Nature of the Marle itſelf, as that is the moſt important.

If the Farmer upon thoroughly conſidering the Nature of his Land, determine after eight or ten Crops upon the Strength of his Marle, to have Graſs, he muſt manage according to the Nature of the Marle that he uſed.

If it were a ſtony or a ſandy Marle, or if it were any of the purer Kinds, he has nothing to do but expect the Graſs when he lays the Land for it, for without any farther Aſſiſtance it will come with great Strength and Freſhneſs: but if it were a clayey Marle that he uſed, ſo much of its binding Quality will remain after the Richneſs has been drawn away by theſe ſucceſſive Crops, that unleſs ſomething be done to help it, there will be but a very poor Appearance of Graſs. Foreſeeing this, he is to uſe the proper Remedy; that is, he muſt give it a Dreſſing of Dung and Lime toward the End of the Time. By this Means it will yield him two or three Crops more, and excellent Graſs afterwards.

It is impoſſible to give one and the ſame Direction for all Lands, as to the Times of marling, and what may be reaſonably expected from them; for the Nature both of the Marle and of the Soil, make an endleſs Variety; but the Farmer will ſee by his Crops when the Land needs to be refreſhed.

CHAP. VIII.

Of the vaſt Fertility of marled Lands.

TO encourage the Farmer as much as poſſible to the Practice of this excellent Part of Huſbandry; I ſhall add ſomething of the Advantages of the Practice, which are ſo great, that I am ſenſible he who has not lived in Counties where it is commonly uſed, will not eaſily believe the Accounts. However, having Truth for my Guide, I ſhall ſpeak freely, and refer the Cauſe to the Determination of experienced Perſons.

In the firſt Place, the Quantity of Corn that will ripen upon a well marled Land, is much greater that than which can have Nouriſhment on any other, for there is nothing whatſoever ſo full of real Nouriſhment for Corn as Marle.

I have ſeen a Piece of Ground ſo exceedingly barren, that the common Heath Ground is not worſe, try'd with Marle to the greateſt Advantage. That Soil which would hardly afford Nouriſhment to wild Graſs or Weeds, being well cover'd with Marle, has yielded a prodigious Crop.

It was in Buckinghamshire I ſaw this Experiment, the moſt fairly try'd by a Gentleman who had diſcover'd a good, fat, but ſomewhat clayey Marle upon his Eſtate: he order'd an Acre of this barren Land, that in the Memory of Man had hardly let for any Thing, to be cover'd with four hundred Load of Marle. The Eyes of all the neighbouring Farmers were upon him, and the firſt Year they began to laugh at him as a Schemer, for it did not yield much; but the three ſucceeding Years, though he did no more to it, the Crop was larger than on any of their beſt Lands.

This is Fact: and is not this a plain Way for a Farmer to make a Fortune. Let him ſee there is Marle to be had; and then let him take a Piece of ſuch Ground in a proper Manner; he will have it for little, and it will yield more than the fineſt Lands in the Country.

He who ſhall attempt to make himſelf in this Manner, need never be afraid of the Expence of Dreſſing the Ground. Let him firſt take Care according to the Rules before laid down, that the Marle he uſes be a proper Kind for the Soil, and it will anſwer at any Price.

The Cheshire Farmers who uſe ſo monſtrous a Quantity of Marle, and often fetch it a great Way into the Bargain, never find themſelves Loſers, except by the Folly of ill-matching the Soil and Kind. When theſe ſuit one another, though they beſtow twenty Pound an Acre upon their Land, as they ſometimes do, laying on the Quantities before mention'd, they always find it worth while.

The great Advantage of Marle, is its laſting Virtue, for according to that is to be counted the Expence; good Dung is worn out in three Years Crops, and muſt be renew'd: but the marling laſts thirty in ſome Places. In this Caſe, though it coſt ten Times as much at firſt, the Price is the ſame in the End: and there is no Proportion between the Crops on dunged Land, and marled.

There are Years when moſt other Lands fail: but it is the Advantage of Marle that it ſtands all Seaſons. Thus when others have poor Crops, he that marles his Land has plenty-full Harveſts. This enriches him doubly, becauſe of the advanced Price of Corn in thoſe Years, and at the ſame Time it is a Benefit to the Country.

In fine, there are many Ways by which the Huſbandman may with Care and Induſtry get himſelf a Fortune, but none ſo ſoon as by this.

To theſe Obſervations of my own, I ſhall add a Letter from a very worthy and experienced Gentleman in Shropshire; containing ſome Things, which as they came ſo well from his Hand, I have not mention'd before.

To *****

SIR,

"Whereas I underſtand you have been making "Enquiries about the Nature and Uſe of Marle "in this Part of England, deſigning to print "your Obſervations, I take the Liberty, tho' a "Stranger to you, to contribute my Mite to "ſo good a Work: and you may depend all I "ſay is true, for I have try'd it. I muſt needs "ſay our Farmers know the Uſe of Marle well "enough on their Corn Lands, but they don't "uſe it on Paſture and Meadow Grounds ſo "much

" much as they might. I have for many Years " had better Hay, and better Feed for my Cat- " tle than any of my Neighbours: and though " I tell them it is becauſe I marle my Graſs " Grounds, they won't imitate me. But I aſ- " ſure you from Experience, it is very profit- " able. I once damag'd a fine Meadow by lay- " ing on a clayey Marle, and another Time I " buried the Graſs by loading it too much: " but now I have found by frequent Trials, " what is the right Sort and right Proportion, " I never fail. I lay a light crumbly Marle " upon my Graſs Grounds, not minding the " Colour, and I allow twenty Load to an A- " cre; this always pays ten-fold. Another " Thing I muſt needs tell you, which I have " learn'd from Experience. When I deſign to " break up a Piece of Ground, I marle it well " two Years before. I allow for this thirty " Load of good Marle to an Acre; by this " Means my firſt Year is as good as ſome " People's ſecond or third after marling. Then " there is another Thing upon my marled plow'd " Land; I don't begin with Wheat as others " do: I ſow for the firſt Crop Oats, the Land " is in Heart enough to yield them well, and " then the three or four next Crops I have " Wheat or Barley. I always do another Thing " particular, that is, I harrow in the Marle " juſt before I plow it, and thus I mix my " Marle better with the Soil than they ever can " do. I have at one Time or other try'd the " different Grounds in my Poſſeſſion, with dif- " ferent Quantities of Marle; ſome require " more, ſome leſs: but upon a Medium, I " think between a Hundred and a Hundred " and fifty Load to an Acre is the due Propor- " tion. I have one Field that ſwallow'd above " two Hundred Load to the Acre, but I am " ſenſible now that was becauſe I uſed a wrong " Kind. I find by Experience that my flat " Lands do beſt for Marle, for it does not " well lie upon the others, 'tis ſo eaſily diſſolv'd " and waſh'd away by Rains: I always allow a " larger Quantity to thoſe Fields, but they do " not ſucceed ſo well. If theſe Remarks can be " of any Uſe, I ſhall be very glad to have given " any Help to your publick ſpirited Deſign; " who am,

Worthy SIR,

Your humble Servant to command,

WILLIAM HUNSDON.

CHAP. IX.

Of the Uſe of Mud as a Manure.

HAVING begun this Treatiſe on Manures with Marle, I ſhall proceed to examine ſuch others as are of an earthy Nature, before I enter on thoſe of the ſeveral other Kinds.

In this Courſe the natural Choice for the next in order falls on Mud, for although Mud is in its Origin and Nature different altogether from Marle, yet it more than any other Kind reſembles it in ſome of its Effects.

Mud, properly ſo called, is the fineſt mellow Earth, waſh'd and worn to a ſurprizing Fineneſs by the Action of Water. This is the Condition of fine and pure Mud: of the other Kinds I ſhall ſpeak preſently. This is ſuch as is drag'd out of the Bottoms of Rivers, where it has been many Years collecting, and where Sand and all other Foulneſſes whatſoever are thoroughly waſh'd from it.

No one will wonder that I ſay this, in ſome of its Properties, reſembles Marle. It is the ſofteſt, fatteſt, and melloweſt of all earthy Subſtances after that; and like Marle it breaks with the leaſt Rains, and crumbles away: ſo far they are alike, as alſo in giving great Fertility: but Marle is a particular Subſtance, and has a laſting Quality of enriching Land, whereas Mud is only Mould in a particular Form, and its Effect is of no great Continuance.

The next to the Mud of Rivers is that of Ponds: but this is leſs pure and fine; it is often clayey, and generally has ſome Mixture of Sand.

The laſt Kind to be named is, that Mud which is thrown up in the Cleanſing of Ditches. This is the pooreſt and worſt of all: but even the worſer Sorts are not to be rejected or deſpiſed; for they have their particular Uſes which the very fineſt would not anſwer ſo well.

The Mud of Ditches, eſpecially thoſe by Road Sides, is full of Grit and Sand, blown in with the Duſt: it is ſhort enough, but wants Mellowneſs.

The firſt Thing the Farmer is to do in theſe Matters, is like what he is to do in reſpect of his Marle. He muſt learn to diſtinguiſh theſe three Kinds of Mud by the Names of River Mud, Pond Mud, and Ditch Mud; and then conſider from their Nature and from Experience, what Soils each of them will ſeverally ſuit.

As Marle is moſt uſed on plow'd Lands, Mud is moſt frequently laid on Paſture and Meadow Grounds. But this need not be eſtabliſhed as an univerſal Rule. We have ſeen how Marle may be uſed with Advantage on Paſture Grounds; and Mud will alſo help many Corn Lands.

Marle is commonly uſed alone, and Mud with other Ingredients; but in ſome Inſtances Marle may be mix'd alſo; and in ſeveral Caſes Mud may be beſt uſed alone.

From the different Nature of the Mud it is qualified to anſwer different Purpoſes. River Mud is proper to give Fertility, and nothing elſe: for its Richneſs is all its Character. Pond Mud will enrich, and at the ſame Time give a Body to the Soil from the Clay it uſually contains; and Ditch Mud though it will leſs enrich, will ſerve better than any to break a tough Land.

When Mud is to be laid on a plow'd Land, this is uſually the Kind.

From this Conſideration of their Nature, the Farmer will be led to a general Notion of their Uſe, and the Lands to which they are ſuited. Thus the River Mud is proper for Meadows and Paſtures of a mellow Soil, that want nothing but a Recruit of that fine Mould, which the ſeveral Growths have waſted and drawn forth;

Pond

Pond Mud is beſt where the Soil is too light and crumbly; and Ditch Mud is preferable to both on a clayey Ground.

Mud, eſpecially that out of Rivers, has this particular Quality, that it mixes in a favourable Manner with the finer Part of Dung. This I have obſerved ſeveral Times in my own Meadows. When I have given them a Sprinkling of Mud and Dung mix'd together, after a few Showers going over the Ground, I have found the ſtrawy Part waſhed clean, and nothing but that remaining; the Mud and the rich Part of the Dung being wholly gone down into the Land: and the next Crop has ſufficiently found their Effects.

People who ſtudy the Growth of Plants, talk greatly of the Value of virgin Earth, that is, Earth on which nothing ever grew. River Mud is the neareſt this virgin Earth in its Nature, of any thing whatever.

I have ſeen in ſome Parts of Northamptonshire, the fine black Mould which they there call the moory Soil, laid upon dry gravelly Grounds with great Succeſs; the Mud of Rivers would anſwer this Purpoſe better: this I affirm from Experience; for having adviſed an Huſbandman of that County, who uſed to take this black Soil out of the Fen Lands for his ſtony Paſtures, to uſe Mud dragged out of the River Nen, or Nine as they call it, in its Place; he has ſince acknowleged to me, by Letter, that he found he could dreſs his Paſtures this Way at leſs than half the Expence, and they produced better.

I adviſe the Farmer who has dry Paſtures, whether they be of a ſtony, gravelly, or ſandy Nature, to uſe this Manure preferably to all others; but let him obſerve the following Directions:

If the Land be entirely of a looſe Nature, let him uſe the Pond Mud, mix'd with rich well rotted Dung; and lay it on in a good round Quantity.

If the Soil be mellow, and only require to be recruited and put in Heart, after ſeveral Growths that have exhauſted it, let him mix pure River Mud with the Dung of Poultry or Sheep, and ſcatter this lightly over the Ground. A very little of this anſwers the Purpoſe; and it is beſt to uſe a little at a Time, and repeat it often.

If the Soil be clayey, let him take the Mud of Ditches, and make a Mixture of it with Chalk and rotten Dung: this being ſpread tolerably thick, will break and mellow the Ground, as well as give it Warmth and Richneſs.

I know a Farmer in Lincolnshire, where there are as many fine feeding Grounds, as any in moſt Places, who always excelled the whole Neighbourhood in this Reſpect; and it was by means of a Compoſt of his own inventing, of which he gave me the following Account: I place it here, becauſe Mud, of which we treat in this Chapter, was the material Ingredient.

He made choice of a Piece of low Ground near his Yard, where the Drainings of the Yard naturally came; he there dug an Hole eight Foot deep, the Soil was a mellow Earth, and at this Depth it reſted upon Clay; and there was ſome Sand and Gravel, and a thin Bed of light Clay between. He made his Diggers throw up the good Soil on one Side of the Pit, and the Clay, Sand, and Gravel, on the other.

The Pit being thus ſunk, he threw in, firſt of all, ſome Litter, and upon that a Layer of large Hedge Weeds, that were not run to Seed; over theſe he threw in the Soil that had been laid by itſelf; then he threw Cow Dung in a good Quantity. When this was done, they drag'd up the Weeds out of the neareſt Waters, and laid in a great Bed of them, then they cover'd all three or four Foot deep with rich Pond Mud: upon all this they threw in more Earth, from the parings of Banks, and cleaning of Ditches, and then laid over all, more Litter to ſtop the Wet, and let it drain there.

This Matter he let lie a conſiderable Time, all the while rotting together, and receiving the rich Drainings of the Yard. When all was mellowed together he dug it out, and ſpread it lightly upon his Paſture Grounds; and to this was owing that particular Encreaſe.

It is in every Farmer's Power to imitate this Practice. I am a Witneſs that it will excellently anſwer the Intent in Graſs Grounds, and I believe it would do very well upon the mellow Soils in Corn Lands, but this has not been try'd.

CHAP. X.

Of the Uſe of Clay as a Manure.

IT may ſeem ſtrange to the unexperienced, that Clay, which, when it makes the eſſential Part of a Soil, requires more manuring than almoſt any other, ſhould itſelf ſerve as a Manure; but Practice ſhews that it anſwers, in this Caſe, excellently, when uſed with Diſcretion. And indeed, as the Barrenneſs of moſt Soils conſiſts in the Abundance of ſome one Ingredient in the general Mixture; there is ſcarce any one Kind that may not ſerve as a Manure for ſome other.

Nature, when ſhe ſucceeds very happily, often does it no other Way than by a due Mixture of ſeveral unpromiſing Ingredients; or of ſuch Things as might, of themſelves, be called unfruitful. The due Mixture of one with another, is the great Matter.

Thus Sand is of itſelf barren, nor will a little mellow Earth mix'd with it, render it fruitful: in the ſame Manner Clay is in itſelf barren, and tho' ſome Mould be mixed with it, 'tis ſtill hard, tough, and fruitleſs; but when Clay is added to the Sand and Mould of the firſt named Compoſition, or when Sand is added to the Clay and Mould in the ſecond, either Way there is made a loamy Soil, which is ſufficiently fruitful.

We ſee therefore how it is that Nature gives Fertility to theſe unpromiſing Ingredients; and in the ſame Manner we can give it by Art. The firſt Buſineſs is to know what makes the Soil barren; and the next to ſupply its Defect. Thus we can add Sand to a clayey Soil; a Clay to one that is ſandy: and in this Light it is that Clay, which is barren in itſelf, yet under proper Directions, ſerves as a Manure to give Fruitfulneſs.

Clay is, upon this Principle, uſed alone in Staffordshire, and ſome other Counties, as a Ma-

Manure to ſandy, and alſo to gravelly and ſtony Lands. For this Purpoſe Clays are taken juſt as they came out of the Pit; and the Difficulty of mixing them well with the Soil, which is in this Caſe the Farmer's greateſt Trouble, is very well repaid by the Fertility they give.

The Principle upon which Clay becomes a Manure in theſe Caſes is very plain. A loamy Soil is preferable to a dry Sand, or a ſcorching naked Gravel; if Nature had mixed ſome Clay with theſe gravelly or ſandy Soils, they would then have been loamy Soils, and would conſequently have been more fruitful. Now what Nature might have done, the Farmer in this Caſe may do, as before ſaid. In adding Clay he converts the ſandy to a loamy Soil.

In this Caſe the Clay acts in a double Capacity; in the firſt Place it gives a Firmneſs to the Soil, enabling it to give a proper Fixture to the Roots of the Corn, and to retain other Manures; and in the ſecond, by its natural Coldneſs, it tempers the ſcorching Heat of the others, which in dry Summers burn up the Crop.

Clay from the Pits is better for this Purpoſe, than ſuch as is taken from the Surface of the Earth; becauſe it is purer, and never having had any Growth upon it, 'tis ſo far of the Nature of a virgin Earth.

The beſt Clay for the Uſe of theſe abſolute ſandy and gravelly Soils is the red, the next beſt the yellow. But when there is a fairer Mixture of Earth with the Sand, then the blue Clays anſwer beſt; for there is ſomewhat of a Fatneſs in them which tends to the Quality of Marles.

I would, by all Means, adviſe the Farmer who has a barren, ſandy, or gravelly Soil to deal with, to uſe the red or the yellow Clay as a Manure. He may have theſe Lands cheap; and once manuring them will laſt for his Life.

There is ſomething which Clay, uſed as a Manure, enjoys in common with Marle, that is, the laſting Fertility it gives: in this Reſpect it even exceeds Marle, for the Effect laſts longer.

I at this Time know ſome Lands that have been dreſs'd with Clay near thirty Years ago, and retain the Fertility yet; and I dare ſay will hold good ten or twelve Years more. There can be no Miſtake in this Matter, becauſe in the Inſtance I name, which is upon the Edge of Buckinghamshire towards Middlesex, it was only one Farmer who uſed a yellow Clay upon his ſandy Field. The Time is well known when this was done; and his Crops at this Day are greatly richer than thoſe upon the other Fields, from which he is parted only by an Hedge; and which had all the ſame natural Soil.

There cannot be a cheaper or readier Manure than Clay, ſo that it is ſtrongly recommended that Way; and we ſee fair Experience ſhews its Value, and the certain and laſting Profit that attends its Uſe.

As to Quantity, I am in this as in all other Reſpects, for uſing Moderation, I know too little of any Manure cannot do any good; and at the ſame Time I am for making up the natural Soil to Fruitfulneſs, not for laying another Soil in the Place of it. I would adviſe the laying on about Seventy-five Load to an Acre; to be encreaſed or diminiſhed according to the particular Circumſtances: and from what I have ſeen I may tell the Farmer who ſhall practiſe this Method, not to be diſheartened, if it ſeem at firſt to want Succeſs

There requires a thorough mixing of the Clay with the natural Soil, to bring it to any conſiderable Encreaſe of Fertility; and with all the Pains the moſt induſtrious Man can take, this is not to be done at once. A tough Clay, though laid on ever ſo carefully, will remain in Cakes and Lumps, in ſome Degree, for at leaſt a couple of Years.

Upon this depends the Circumſtance of the Improvement not being ſeen at firſt. As the marled Lands do not come to their full Richneſs till the ſecond Year, theſe clay'd Fields are not at the beſt till the third or fourth. But by this Time, with good plowing and harrowing, the Clay gets well mix'd in; and then it is another Soil, and produces accordingly.

I have known the firſt Year's Produce of a clay'd Land, rather leſs than it uſed to be when left to itſelf. But from this Time it has grown better and better, till the fifth, ſixth, or ſeventh Year; and from that Time has held its Degree of Fruitfulneſs, as if it would continue without End.

The Farmer is not to expect ſuch Crops upon one of theſe Lands, as upon a good Soil well marled, where the Rent is many Times higher, and the Manure coſts many Times as much; but computing all Things, the Improvement is at leaſt equal.

Thus far I have conſider'd Clay in its native State for a Manure; but I muſt not quit the Subject before I have taken a proper Notice of it, as it is altered by Art, for the Service of the Farmer.

Though Clay, in the Lump or Cake, has been found to be very barren in all Parts of the World; yet it has been ſeen in many Places, from different Accidents, that Clay, when reduced to Powder, makes very good Mould.

Upon this has been eſtabliſhed the Practice now uſed in many Places, and getting very deſervedly into Uſe in more, of calcining Clay, or burning it, for the Uſes of Huſbandry: the Advantages of which are very great.

It appears plainly, from the Fertility of powder'd Clay, that it is not the Subſtance of that Earth which is an Enemy to the Growth of Plants, but only its compact Texture. Now nothing is able to break that compact Texture of Clay like Fire; and therefore burning has been diſcover'd for this excellent Purpoſe. There are, at this Time, many Kilns built for that Uſe, in different Parts of the Kingdom; in ſome of which many thouſand Loads of red, yellow, and blue Clay are burnt yearly: and it were well for the Country, if the Number were twenty Times as great.

The Fire takes away all the Toughneſs of the Clay, and in this half-burnt Condition it is a moſt excellent Manure for Corn Lands of the looſer and dryer Kind: breaking eaſily, and mixing thoroughly with the Soil in a very little Time.

There is alſo a black Clay called Urry, found in Coal Pits, which is naturally crumbly, and mixes

mixes readily with any Soil, giving it great Fertility; it uſually lies juſt over the Coal.

Let the Huſbandman learn by this, not to deſpiſe any thing as a Manure from its appearing unlikely to give Fertility to the Ground; for at firſt Sight nothing could ſeem more unlikely than Clay: and let him learn not to deſpiſe Projects; for this burning of Clay was at firſt abuſed under that Name.

CHAP. XI.

Of the Uſe of Loam as a Manure.

I HAVE ſhewn in what a profitable Manner Clay is employ'd as a Manure, and in the ſucceeding Chapter ſhall ſhew how Sand is uſed to the ſame Purpoſes; Loam, as has been explained already, is only a Mixture of Clay and Sand: therefore as theſe are ſeverally uſeful to ſuch Lands as want one or the other, this Mixture of them is, in ſome Places, employ'd in the Dreſſing of Lands that want both. I have placed it next after Clay as neareſt of kin to that Earth, and ſhall add what I have ſeen on the Subject of its Uſe as a Manure, for it is only from Experience I ſhall write of it.

The Uſe of Loam, or loamy Earth, as a Manure, is more limitted than that of the others; but it is in the narrow Bounds allowed to it, not trifling.

Clay enriches a ſandy Soil by giving it a Body: Sand improves a clayey Soil, by breaking its Toughneſs; it is alſo uſed with Succeſs on ſome gravelly Grounds, but there are ſome of theſe with which Clay will never mix: for thoſe Loam, or a loamy Earth, is the only Manure.

When a gravelly Soil has a good deal of Sand in it, as is frequent; or when it is full of ragged Flints, or rough Pieces of Stone, it will receive the Clay that ſhall be laid on it as Manure. But when the Soil conſiſts only of ſmooth round Pebbles, and a little Mould, the Clay will never mix among it. Of this I ſaw an Inſtance lately in KENT, which I ſhall ſet down as an Example of the Uſe of Loam.

THOMAS EDMUNDS had a couple of Fields, the Soil of which was made up of round blueiſh ſmall Pebbles, and a little hazel Mould. But to look upon the Fields, any one would ſuppoſe them to be plain naked Gravel, for the Rain continually waſhed in the Mould, and only the Stones were to be ſeen.

He had try'd Dung upon it a Year or two to no Manner of Purpoſe. The Gravel was too hungry for that Manure. A clayey Marle would have done well on this Soil, if laid thick enough, but there was none near; he had been adviſed to lay on Clay, which he try'd only on one Field, having no great Opinion of it. The Clay never mix'd with the Soil at all, but lay looſe after all his Plowings, and did more Harm than Good.

The Clay he had uſed was yellow, and the Neighbour who gave him the Advice thought the Colour was the Reaſon of the Failing. There was a Pit of Brick Earth open hard by, this was a rediſh Loam. He took this for red Clay, and adviſed EDMUNDS to try it on the other Field. So careleſs are theſe People, in their own Concerns, that they don't know one Earth from another.

He laid on the Loam two and twenty Loads to the Acre, and after a couple of Plowings it perfectly well mix'd with the reſt. Not only the Pebbles hung very well in it; but the Mould turn'd up by deep Plowing, mingled with the reſt entirely and perfectly.

This Field had been worked four Years when I ſaw it, and it was then in excellent Heart. The very Nature of the Soil was chang'd: one would not have believ'd, by looking on it, that it ever was the ſame with that of the other Field. He is now at work upon that in the ſame Manner, and I doubt not but he will find the ſame Benefit.

I once in HERTFORDSHIRE ſaw Loam laid on a very dry ſandy Soil. I confeſs this at firſt ſtartled me: becauſe adding Sand to Sand ſeem'd ill Huſbandry, but he was a ſenſible Man that did it, and he gave me a very good Reaſon.

This was a hard ſandy Piece of Ground which would never take Clay: he had try'd many Times to dreſs it with that Manure, but it would never break nor mix. This Loam contain'd a great deal of Clay, with but a moderate Quantity of Sand, and it broke and mix'd freely enough with the Soil. So the Farmer had the Advantage of the Clay which was contain'd in the Loam, and the Addition of Sand to his Land, that was before too ſandy, was not great.

It is thus the Huſbandman muſt ſometimes compromiſe Matters, Benefits cannot always be had entire. The Harm he did his Ground by the Sand that was in this Loam, was much leſs than the Good it receiv'd from the Clay; and therefore, on ſtating the Account, the Ballance was in his Favour.

I have ſeen Loam uſed as a Dreſſing to a ſmall Field of a chalky Soil. This, though not a common Practice, is very reaſonable, and the Benefit was very conſiderable.

Chalky Soils are hot, dry, and looſe; now the very Nature of a clayey Loam is cold, moiſt, and tough. Theſe Qualities in the Loam being the oppoſite ones to the Fault of the Chalk, they muſt needs correct and improve it. Thus that is often founded upon Reaſon which appears the moſt ſtrange.

Loam, or a loamy Earth, may alſo be uſed with Advantage on theſe looſe mellow Soils, which they have in LINCOLNSHIRE, which are ſo looſe and light, that they will not give Hold enough to the Roots of the Corn. Clay would be an Advantage to theſe Lands, but as Clay will not readily mix with them, there being nothing there to break it, a Loam, conſiſting of a large Proportion of Clay to a little Sand, will excellently anſwer this Purpoſe: the Sand diſpoſing the Clay to break and mix with the Mould, which otherwiſe it would not; and the ſmall Quantity of Sand that goes in along with it, being of no bad Conſequence.

I have been the larger on this Head, becauſe Loam, or loamy Earths, are always at hand; and their Uſes in Huſbandry are very imperfectly known. We ſee almoſt any thing will anſwer the Purpoſe of a Manure on ſome Soil or other; and it is good to know all that can be uſed, that when one cannot be had another may.

Loam is one of thoſe Manures that leave Room for the Advantages of any other. Dreſſings of Dung, and all the rich Kinds, come very well upon the Lands after the Loam, which puts them in a Condition to receive, and to detain their beſt Parts; and on this depends a great deal of the Succeſs of Huſbandry.

A great Art is, not to throw the rich Manures away, which is eaſily done upon what are called hungry, and looſe Soils; Loam gives theſe a Body, and after that they will retain whatever is given them.

CHAP. XII.

Of the Uſe of Sand as a Manure.

THE practical Huſbandman will not be ſurpriz'd to hear of Sand, which is in itſelf the moſt barren of all Things, uſed as a Manure, becauſe he has doubtleſs ſeen it ſo employ'd with Succeſs: nor will he who is but beginning to learn that Profeſſion, wonder at ſuch an Account here: becauſe he has been prepared for it by what has been ſaid occaſionally before.

Every Farmer knows that Sand is good to be laid on Clay Grounds: but we ſhall in this Place conſider its Uſes a little farther.

In order to the more perfect underſtanding of the Advantages ariſing from a Uſe of Sand; and to prevent Miſtakes which might obſtruct the natural Good of uſing it on proper Lands, the Farmer muſt recollect what has been ſaid in a former Chapter concerning the three Kinds of Sand.

Theſe are Sea Sand, River Sand, and Pit Sand. Sea and River Sand where they are both ſharp and ſtony, are the ſame Thing originally, being both no other than Pit Sand waſh'd clean; but they differ in this capital Reſpect, that the one is impregnated with Salt, and the other not. There is another Kind of Sea Sand, as before obſerv'd, which is made up only of Shells broken to Pieces: and ſome ſhelly Matter is frequent in moſt Sea Sand.

For the Purpoſes of Huſbandry therefore, following this natural Diviſion, we are to diſtinguiſh four Kinds of Sand.

1. Pit Sand; conſiſting of little Stones, with Earth among them.

2. River Sand; conſiſting of the ſame Stones only, the earthy Part being waſh'd away.

3. Sea Sand, conſiſting of the ſame Stones waſh'd clean in the ſame Manner, but with a Saltneſs from the Sea Water, and ſome Pieces of Shells among them; and ſometimes farther enriched by decay'd Sea Plants, and Animals.

4. Shelly Sea Sand; conſiſting altogether of broken Pieces of Shells impregnated with Salt, from the Sea Water.

To theſe may be added a fifth, but baſtard Kind, that is, the Grit of Roads.

Theſe ſeveral Kinds the Farmer is careful to diſtinguiſh, for they are very different in their Effect and Value; and ſome of them are able to anſwer Purpoſes to which the others are not at all fitted.

Where the Uſe of Sand is only to break and divide a tough Soil, the cleaner it is the better; becauſe the cleaner the ſharper: therefore River Sand is preferable to Sea Sand for this Purpoſe. The common Sea Sand owes its particular Value above that of Rivers, to the Salt: the Uſes of which will be ſhewn at large in a ſucceeding Chapter, where Salt will be treated of as a Manure.

If the Farmer have cold clayey Grounds, where nothing is required but to break and warm them, common Sand anſwers this Purpoſe.

Pit Sand will do; but any other Kind anſwers better. The Farmers ſay Pit Sand has not ſo much Fertility as River Sand; but the Truth is, the earthy Matter that is among it blunts the ſharp Edges of the little Stones, which are to do their Buſineſs by breaking and dividing the Clay.

For this Reaſon clean River Saud is much better on that Occaſion, and where that is not to be had, it is better to uſe the Grit out of Roads, or the ſandy Subſtance which remains in the Roads, when the light Dirt has been waſh'd away by the Rains. This is very ſharp, and breaks the Earth excellently.

When beſide Warmth, the Farmer wants to give Richneſs to his Land, let him mix well rotted Dung; or freſh Hog's Dung, or Poultry Dung with his Sand. In this Way of uſing it, Pit Sand does as well as any, and I have ſeen very great Effects of this mix'd Manure upon a Piece of Land in Shropshire, where before nothing grew but the pooreſt of Weeds.

Another Way there is by which the Farmer may make common Pit Sand very uſeful: this is by laying it in the Way of enriching Ingredients. Thus when he cannot fold Sheep, let him have a Sheep-houſe to feed them in, and let him lay on a deep Covering of common Sand. This as it receives the Dung and Urine of the Sheep, will become very rich, and may be removed from Time to Time, and freſh put in, till a large Quantity is well impregnated.

Pit Sand does better for this Purpoſe than any other, becauſe the earthy Matter that is about it detains the Moiſture that drains upon it.

When the Huſbandman is to improve a cold clayey Land with Sand, let him remember that all he lays on it will be of no Effect without frequent and careful Plowings; by Means of theſe, the Sand mixes thoroughly with the Clay; and it would otherwiſe in great Part run in between the Clots, and lie unmixed and uſeleſs.

Clay thus mix'd with Sand yields to the Plow, and receives the Rains freely: and it takes any Kind of rich Manure afterwards.

Loamy, gravelly, or chalky Soils, can never be improved by Sand, merely uſed as Sand; and I ſuppoſe no one would think of laying it upon his mellow Earth, unleſs he wanted to impoveriſh inſtead of improve his Land. The only Soil therefore on which it can be uſed in that naked and ſimple State, is the clayey. In delivering therefore the Methods of uſing it on that, I have ſhewn all the Uſes of Pit Sand, River Sand, and the Grit of Roads.

We come now to the Uſes of the two Kinds of Sea Sand; the proper Sea Sand, which is like River Sand, but Salt; and the ſhelly Kind.

Theſe two are not ſo limited in their Uſe; for Salt and Shells are both of them very ſerviceable for the enriching of Land: and the Sea Sands are therefore uſeful in Proportion as they partake of them. There is alſo a farther Conſideration in reſpect of ſome Kinds of Sea Sand; that is, that it contains a great deal of decay'd Animal and Vegetable Matter, from the Bodies of Fiſh, Weeds, and other Things that die and rot among it. 'Tis only ſuch Sand as lies quiet that can have this Advantage, but it is very great, for nothing is ſo rich as decay'd Plants and Animals.

The Sea Sand that is taken from a plain Shore, is commonly no Way enrich'd but by the Salt it contains: that which lies in Creeks and among Rocks, where it is leſs diſturb'd, and where more Weeds grow, and more ſmall Animals live, is commonly of the rich Kind laſt mentioned; and that which is taken up on Beaks and Points of Land, uſually conſiſts almoſt entirely of Shells. The Point of the Iſland of SHEPEY in KENT, is cover'd to a great Depth with broken Shells in this Manner. At the Surface there lie whole Shells, and large Fragments; but under theſe is a Quantity of them broke ſo ſmall, that they paſs for Sand, and are called ſo by the Fiſhermen, though the Point itſelf is called SHELLNESS.

For the Farmers more perfect Information, I ſhall ſpeak of theſe three Kinds of Sea Sand ſeparately.

Firſt, of that which has its peculiar Virtue from the Salt only, having few or no Shells, or Fragments of Shells among it: this is beſt when it is ſofteſt. The Harſhneſs of common Sand is a valuable Quality in it, becauſe it is uſed principally to cut and break the Clay: but as this Sea Sand is employ'd to enrich, there needs not in it this Sharpneſs: and the Sand of the ſmalleſt Grain is obſerv'd always to be the ſalteſt.

Of this Kind of Sand the redeſt is prefer'd to that of other Colours, by the Farmers upon the SUSSEX Coaſt and elſewhere. This they have learn'd from Books: but what is there written has been founded only on particular Inſtances, and ſhould not have been made general. The People of CORNWALL were the firſt that uſed Sea Sand as a Manure: and they found the red Kind the beſt; the Reaſon of which is, that the red happens to be the fineſt grain'd Sand on the Coaſt of CORNWALL; but this is not the Caſe every where: on the contrary, they have on the SUSSEX Coaſt a pale yellow Sand, which is much finer and better than the red; but they prefer the red, becauſe they have been told it is beſt.

This may ſhew the Benefit of our Method in this Work, of explaining every where the Reaſon, as well as laying down the Fact. Otherwiſe what is meant for Inſtruction often miſleads.

The Farmer who has his Choice of Sea Sand, will know for the future that the ſofteſt and fineſt Sand of this Kind, is the beſt without having any regard to its Colour.

N° 5.

They ſay in SUSSEX the largeſt grain'd Sand gives the moſt laſting Fruitfulneſs, though the fine ſmall-grain'd Sort I have named, has the ſpeedyeſt Effect; and the greateſt at firſt. They fancy the other gives this more laſting Benefit, becauſe they can ſee it longeſt in the Ground. This may be true when it is a clayey Soil that it is uſed upon, but that's a particular Caſe. Otherwiſe the Salt that is among the Sand is the great Enricher; and it is of no Uſe that the Sand remains when that is gone.

Some drag up this Sea Sand from under pretty deep Water, where it is always cover'd by the Sea: but that which lies on the Shores, and is wet and dry as the Tide is in or out, is much ſalter and better. I write this from Experience. But it ſhould always be taken up wet for the Uſe of the Huſbandman, and carried to his Land as ſoon as it is a little drain'd; and then the ſooner it is plow'd in, the better.

The Sand from deep Water coſts moſt, becauſe of the Trouble of getting it up: it commonly coſts twice, ſometimes three times as much as the other. The Farmer naturally thinks it better becauſe it is dearer; but I have certain Proof from repeated Trials, that it is worſe. I have ſeen as much Effect from ten Ton of the Shore Sand, as from fifteen of the deep Water Kind.

The Soil which this Sea Sand beſt ſuits, is a poor clayey or loamy one: the Quantity to be laid on is from eight to eighteen Tun to the Acre: I have ſeen five and twenty Tun laid upon an Acre, where it was ready and came cheap; but this is too much. In other Places where the Sand has been a great Way to fetch, I have known a Farmer ſatisfy himſelf with two or three Tun to the Acre: but he might as well have done nothing.

From theſe ſmall Quantities there can come no good: and from the laying on an Overload, it is eaſy to ſee what Damage may be done. For firſt, the Quantity of Sand may be too much, and the Soil may be injur'd in the End, by being made too ſandy. Then as to the Saltneſs, that may be over-done; eſpecially when the Sand is laid on very wet, as it uſually is where they lay on ſuch great Quantities, and that for the ſame Reaſon becauſe it is near. And we know by all Experience, that although Salt in a due Degree enriches Land, yet in too large a Quantity it cauſes Barrenneſs.

I would adviſe the Farmer to manage this valuable Manure, when he has it conveniently, in this Manner. Let him dreſs his worſt Lands with it: for I have ſeen barren clayey Grounds which produced nothing but Fern, brought to yield very good Crops, by this Uſe of Sea Sand, with a very little Dunging afterwards.

As to the Quantity, I adviſe in general nine or ten Tun to an Acre, and as this Manure takes Effect immediately, I would have the firſt Crop Wheat. In marled Lands it is better to have the firſt Crop, Oats, becauſe the Land does not come to its Strength the firſt Year. But after this Manure, the firſt Crop being Wheat, the Farmer may have three other good Crops of Corn, and after that it is adviſeable to lay it down for Paſture for about five or ſix Years; mowing it

the firſt Year; and afterwards feeding Cattle on it. For it is obſerv'd by all the Farmers, when this Manure is uſed, that the Graſs rais'd from it, exceeds all other Kinds in Sweetneſs.

The Warmth this Manure gives to Land is ſurprizing. The Snow ſcarce ever lies upon thoſe Grounds that have been well ſanded; and partly the Warmth, partly the Richneſs of the Manure, makes a Spring even in Winter.

We now come to the Conſideration of the Sea Sand, taken from ſtill Places among Rocks, and in Creeks: this, beſide its Salt, has ſuch a vaſt Richneſs from the decay'd Plants and Animals, that a little of it goes a great Way; and there is no Land whatſoever that will not be improved by it. Even in ſandy Soils the Addition of the Sand, unleſs it be a very dry one indeed, will do little Harm in Compariſon of the good of the Animal and Vegetable Part.

This is uſed in many Parts of Cornwall with ſurprizing Benefit: beſide the Advantage of Salt and Sand, it contains the richeſt of all Manures, and ſucceeds in a very moderate Quantity: five Tun to an Acre is a very fair Allowance; I have ſeen Crops from it that were aſtoniſhing; it ſuits very well with Wheat, but beſt of all with Barley, and it gives a Richneſs to the Ear. The Stalk of Barley ſown on this Ground is remarkably ſhort, but the Ear ſurprizingly long and thick; 'tis often two thirds of the Length of the Stalk or more. This has been ſaid of the Manure by Sea Sand in general, but in Cornwall where this Barley is ſo fine, I have obſerv'd that it is where the foul Sea Sand, for ſo they call it, has been uſed. In other Places it is very fine, but it is this enrich'd Sand that gives it the great Fruitfulneſs.

The Graſs that grows upon thoſe Lands, that have been manur'd with this Creek Sand, is like the Corn, preferable in Richneſs to any other. This is found by the Graziers, for none feeds Cattle like it: 'tis like the Barley, ſhort but full: it does not run to Stalk, but the Leaves are numerous, and the Head rich. It is always full of white Clover, which is a very nouriſhing Graſs, and there is ſuch Heart in the Land, that the Growth is very ſpeedy, and the Sward always freſh, however it is eaten.

Other Sands may agree with particular Soils; but the Farmer who has this within any moderate Reach, is ſure of a Treaſure: for let his Land, be of what Soil it will, this agrees with it; and it need not be renewed oftener than once in ten or twelve Years.

In the laſt Place, I come to conſider that Sort of Sea Sand which contains a great Quantity of Sea Shells, or which is altogether made up of Pieces of broken Sea Shells, and is thence called Shell Sand. This has the common Advantage of Sand, even tho' it be that conſiſting of Shells only, for it will break and divide a tough Soil: but it has the farther Benefit of enriching it in a very conſiderable Manner.

There are two different Accounts on which Sea Shells enrich a Soil. In the firſt Place, theſe Shells are in their Nature ſomething of kin to Marle, eſpecially when they have been well calcin'd; and that is the Condition of thoſe which are thus broken, and expos'd on the Shores. In the next Place, as they have been a Part of Animal Bodies, they partake of an Animal Nature: and all Things whatever that do ſo, are rich.

This Sand agrees excellently with barren heathy Land, that has a clayey Soil, and is naturally over-run with Fern and Fuzzes. The common Hazel Mould is alſo greatly enrich'd by it; and the Fruitfulneſs which it gives continues a long Time. The Corn which grows on theſe Lands has always a ſhort Stalk, and a large Ear; and the Graſs is ſhort alſo, but it is always thick, juicy, and ſweet.

The Colour of this Sort of Sand may give ſome Rule for judging of its Quality. The more Shells or ſhelly Matter it contains, the richer it is; and the leſs that ſhelly Matter is calcin'd, the longer the Improvement made by it laſts; though on the other hand, the whiter it looks, the ſooner the Effect is ſeen. This is very natural, becauſe the white Shells are calcin'd already, and give out their Virtues at once. The others are to be calcin'd by the Sun and Air as they lie on the Ground: this is done gradually, and the Improvement advances in the ſame Manner.

This is ſeen very evidently in the Effect of the ſhelly Sand in Sussex, and that in Cornwall. The Sussex Kind in general conſiſts of a good deal of yellowiſh Sand, with a great Quantity of broken Shells in white Pieces among it. Theſe are Cockle Shells for the moſt Part, broke by the Daſhing of the Water, and calcin'd by laying on a flat Shore. The Corniſh ſhelly Sand is blueiſh or aſh-colour'd; for it conſiſts of ſome white Sand, with a Quantity of broken Muſcle and Limpet Shells: theſe not being expos'd in general on ſo flat a Shore, are leſs calcin'd by being left dry to the Sun and Air.

The Sussex ſhelly Sand enriches Land immediately in the Manner of Dung; but it does not well ſupport more than three Crops of Corn; after which they have five or ſix Years good Graſs, and then repeat the Dreſſing.

On the other hand, the Corniſh Kind does not ſhew its Effects at once, but the four or five ſucceeding Years it yields excellent Crops of Wheat or Barley; and after that, affords a much ſtronger Graſs, though as ſweet as the other.

CHAP. XIII.

Of the Uſe of Gravel as a Manure.

I AM ſenſible that many Things are mention'd here to be conſider'd as Manures, which will ſurprize the unexperienced Reader; and this of Gravel is one of them. But 'tis from Practice all that is here written on them is deliver'd. Thoſe very Things which of themſelves make very bad Soils, ſerve to improve others. Sand and Clay are two Inſtances of this, and Gravel, as will be ſhewn, is a third.

Gravel making of itſelf a hot Soil, is good to be uſed to thoſe which are naturally cold: this is a firſt general Principle. Cold Lands are moſtly tough: now the Gravel at the ſame Time that

that it warms, breaks them; and gives way to Rains, and to the Roots of Plants.

As breaking the Toughneſs of the Soil is uſually one Point to be aim'd at in the Uſe of Gravel as a Manure; the beſt Kind for that Service, is that which is full of rough and ragged Flints, and other Stones. This will warm a Soil as much as that Gravel which conſiſts only of round ſmooth Pebbles; and will break it a great deal more.

As they are uſually clayey Grounds that are improved by Gravel, the Farmer muſt take Care there is no Clay hanging about the Stones, as is the Caſe naturally in many Pits: and he will do well to have all the large Stones pick'd out, they being only hurtful.

In Buckinghamshire I have ſeen a Clay Field manur'd with a rough Gravel firſt, and afterwards with Dung: and the Conſequence was a very good Crop. The Dung had been thrown away upon it many a Year before; but the Gravel made way for it, at the ſame Time that it warm'd the Soil from its own Nature.

But I muſt inform the Farmer that this was a ragged flinty Gravel, and there were few Stones bigger than a Walnut.

Another Improvement I ſaw by Gravel in Northamptonshire, in a different Way, but this was alſo in a clayey Soil. The Farmer had thrown away a great deal of good Dung upon it, as is often done upon Clays, when at length an Accident relieved him. The Soil was very ſhallow in his Grounds, and underneath it lay a flinty Gravel with a great Quantity of petrified Oyſterſhells among it. He one Year plowed deeper than ordinary, and turn'd up a good deal of his mix'd Gravel with the Soil, and the next Crop was four Times greater than the Land ever produced before in the Memory of the oldeſt Inhabitants.

It is to be obſerv'd, that the Gravel in this Place was improved by the petrified Shells, in the ſame Manner as Sea Sand often is, by the broken Shells that are mix'd among it, as named in the laſt Chapter. Many other Sea Shells when petrified, become abſolute Stone; or there is nothing but a Lump of Stone bearing their Reſemblance; but in Oyſterſhells it is often otherwiſe, and in none ſo much as thoſe of this County: they are turn'd up very frequently, and though in part ſtony, they have always ſomething of the Shell remaining. They are flakey, and ſplit and moulder to Pieces, after being a little expos'd to the Weather, and act entirely as calcin'd Shells. For I have obſerv'd, that wherever there are Sea Shells found in the Earth, if they are not petrified, they are always brittle, and as it were calcin'd.

The only Kind of Soil beſide the clayey, in which it can ever be proper to uſe Gravel as a Manure, is that which is the moſt nearly allied to it, the loamy Soil. I have ſeen where the Sand in this Soil has been ſo little in Proportion to the Clay, that the Earth always roſe in great Clots from the Plow, and got into Cakes with the Wet. In ſuch a Soil I am certain Gravel would be a good Addition.

I don't ſpeak this from Experience, but only from Conjecture, but it is a Conjecture founded on Reaſon. For the Gravel would prevent the Soil from running into great Cakes and Clods; and the Sand would then be able to keep the leſſer Lumps a little divided.

CHAP. XIV.

Of the Uſe of Stone as a Manure.

EVEN after treating of Gravel as a Manure, I ſhould be afraid of naming Stone on the ſame Occaſion, were not ſuch uſe of it ſupported by Practice, and confirmed as to the Benefit by frequent Experience in Oxfordshire, and ſome of the adjacent Counties.

The Practice, however ſingular it may appear, has its Foundation in Reaſon. In ſpeaking of the Soils in the firſt Book, I have nam'd ſome of the ſtony Kind, which the Farmer likes better than the ſame Kind of Grounds where there are no Stones among the Earth.

I have alſo in treating of Gravel, adviſ'd the Huſbandman to preſer ſuch as has rough and irregular ſhap'd Flints among it, to that which conſiſts entirely of round and ſmooth Pebbles: and that for a very plain Reaſon.

Now on theſe two Obſervations, the Uſe of Stone as a Manure, is ſeen as ſupported both by Experience and Reaſon. If of two Fields otherwiſe the very ſame in Soil, the one having Stones among it, is more fruitful; and the other not having any, is barren; it is plain that Stones being laid on a barren Ground of that Kind, will improve, and make it fertile.

In the ſame Manner Reaſon ſhews, that if that Kind of Gravel is beſt for Manure which is fulleſt of rough Stones, they being more apt to break the Toughneſs of a Soil; then a Parcel of ſuch rough Stones without any Pebbles at all, muſt be better than any Gravel whatſoever, for that Purpoſe.

Again, as the ſecond Uſe of Gravel is warming the Soil, it is certain that Pieces of Lime Stone, and the like, will anſwer that Purpoſe better, than the Pebbles of which Gravel is uſually, for the moſt part, compos'd, becauſe theſe Stones are in their own Nature warmer than Flints and Pebbles.

Having in this Manner ſhewn the practical Huſbandman the Reaſon of the Thing, I ſhall now add what is known from Practice.

In Oxfordshire it is no uncommon Thing, to meet with large Tracts of a cold, tough, and very indifferent Soil. They beſtow a great deal of Manure of the common Kinds, upon this in ſeveral Places to very little Purpoſe; but about Banbury, particularly at Hornton, they have found a Way of manuring it with the Chippings of Stone to great Profit.

There are Quarries of Stone in that Neighbourhood; and the Pieces that fly off in hewing out the Blocks, are ſpread upon theſe plow'd Lands, and work'd in by Degrees, mixing thoroughly with the Soil, and giving it a laſting Fertility.

It is no wonder the Benefit ariſing from theſe is laſting, for the Manure muſt remain a long Time, and though theſe Pieces of Stone break

by Degrees with the Weather, they ſtill retain their Power of dividing the tough Soil.

We have a very antient Record of the Uſe of Stones, in rendering the Earth fertile. Some Foreigners who came to Syracuse, and practis'd Huſbandry, intended great Improvements in all the neighbouring Lands. The firſt Step theſe indefatigable People took was, to pick out all the Stones from the plowed Lands; and this they did ſo carefully, that after three Plowings there was not a Pebble of the Bigneſs of a Nut to be found any where. They then went to Sowing, but the Lands produced ſcarce any thing. The Crops were nothing to what they had been before. And the new Farmers could make nothing of their Undertaking, till they had laid the Stones on again.

After this they continued their other Labours of deep and often plowing, weeding, and the like; in which they were more induſtrious than any People, and they then ſucceeded. The Manures they had uſed when the Stones were off took no Effect; but as ſoon as they were laid on again, they enriched the Land according to their Nature.

This ſeemed a Sort of Miracle to the People of that Time. They made Nature a Goddeſs, and ſaid ſhe would not be put out of her Courſe. But the Farmer who has read this Work hitherto with Care, and underſtands the Nature of cold Clays, and the Reaſon of their Barrenneſs; as alſo the Effect of Stones in breaking and dividing ſuch Soils, and giving way to the other Manures to enter into their Body, and for the Corn to ſhoot out its Stalks, will be able to give an Account of this impoveriſhing the Land, by removing the Stones, and enriching it again, by laying them again in their Places, without having Recourſe to Goddeſſes and Miracles.

It has pleaſed God, the Creator of the Earth, to cover it with different Soils, and in ſome Places to leave them more barren, in others naturally improved. We are to uſe our Underſtanding in obſerving what is the Kind of that natural Improvement; and our Induſtry in imitating it: for imitating Nature is obeying God.

We ſee from the old Inſtance at Syracuse, and the modern Obſervations in Northamptonshire, that Stones, eſpecially the rough Kind, being in a Corn Land, are a great Advantage to its Fertility. Nor is the Practice of that Part of Oxfordshire I have named, either new or particular. It is not new, for it is mentioned as in common Uſe by Dr. Plot, who wrote near eighty Years ago; ſo that, doubtleſs, it is there a Practice of more than a hundred Years ſtanding; nor is it particular, for I have ſeen it done in Sussex in more than two or three Places. They there lay on the Bits of Stone with the Dung; but the other is the better Practice.

CHAP. XV.

Of the Uſe of Chalk as a Manure.

I HAVE been ſpeaking of ſome uncommon Manures, I now come to one which is well known, and frequently uſed; but which never can be too much conſidered; or when rightly underſtood too much employ'd.

Chalk is one of the moſt diſtinguiſhable Manures in its Effects, which laſt a great while, but are apt to leave the Land poorer than it was at firſt, unleſs ſome Care be taken to prevent that Miſchief.

A great Benefit of Chalk is, that it agrees perfectly well with the two worſt Soils we have. A tough Clay, or a bare Sand, are both greatly improved by it. But of this it muſt be obſerved, as of other natural and earthy Manures, that it makes way for other Dreſſings; and prepares the Ground that it improves, for being enriched by every other Means.

Chalk is a general Name, as has been obſerved before, comprehending many Kinds of this white Subſtance, of different Degrees of Hardneſs, and fit for various Purpoſes; the Farmer is therefore to take Care that he chuſes a right Kind.

The common Servants will be able to inform him, that his Chalk muſt be crumbled to Powder by the Weather, before it is fit to anſwer his Purpoſe. He will therefore naturally and juſtly prefer that Chalk, which is beſt ſuited to receive the Effects of the Air; that is the ſofteſt.

Chalk burnt into Lime, is uſed with great Benefit as a Manure; and this Effect of the Air, in breaking and mouldening it to Powder, is a Sort of Calcination, though in a leſs Degree. It is preferable to the other in the End; for as it is leſs violent, it leaves more Heart in the Chalk, which is the Occaſion why the Effects of Chalk laſt, by many Years, longer than thoſe of Lime, though the Effect of Lime is more ſpeedy.

The Farmer may be ſure that the Chalk which is ſofteſt and fatteſt, is the moſt free to take the Influence of the Sun, Air, and Rains. This will not only break much ſooner, but breaks alſo more perfectly than the ſtony Kind; and it is therefore always to be prefer'd, though brought farther and at more Expence.

The hard ſtony Chalk will ſcarce break at all. I have known many a Farmer make a great Miſtake, by ſuppoſing it would mellow and break when in his Land. He has therefore plowed it in, in Lumps, after its being expoſed the uſual Time to the Air. Such have more than once complain'd, that their Chalk took no Effect; and I have ſhewn two or three of them the Reaſon, by taking them to their Ground, and making them ſee the Lumps of Chalk lying quite unalter'd in the Soil after two or three Years.

There are Chalks ſo ſtony that they will hardly break with the Weather at all. Theſe the Huſbandman is to reject, unleſs he intends to burn them to Lime. The Chalk he is to chuſe is the ſoft mellow Kind, which uſually lies at a ſmall Depth in the Ground, under a Coat of yellowiſh marly Clay. I have found Beds of this Chalk in many Counties; and always cover'd in this Manner.

This Kind really approaches to the Nature of Marle, and a Winter's Froſt and Rain never fail to reduce it to a Condition of mixing thoroughly with the Soil. Being mix'd in this Manner with the toughеſt Clays, it brings them into a light and hollow Condition, in which the Rains and Weather penetrate them thoroughly, all rich

Manures enter perfectly well into their Substance; Corn can easily shoot through them, and they yield with Freedom to all the Instruments of Husbandry.

What an Advantage is this to the Husbandman, to have a Soil that works easily, takes Dung well, and gives free Growth to his Crop, at the same Time that it has a sufficient Body to hold up the Stalk. This is a Benefit he can only have from his Knowledge and Industry. It is the Soil he makes out of a Clay well chalk'd and well dung'd, for there is no such in Nature.

Indeed there is no Instance wherein the Mixture of Soils so plainly shews its Advantage, as that of Chalk and Clay. Both are naturally barren; but being mix'd they are capable of producing any thing.

Chalk takes the greatest Effect upon those Lands, which have no Mixture of it in their own Nature; nor have ever had any of it laid on them before. In these Cases it changes the very Nature of the Soil. One plowing upon a Clay Land that has been chalked, will go as far as three upon one that has not; and such a Soil, instead of being slow in its Produce after this chalking, pushes so fast, and if not preserved by rich Manures, or recovered by due Rest, after a proper Time, will be perfectly exhausted.

To prevent this Accident, which has cast a Reproach upon chalking of Land, that it enriches the present Possessor, but ruins the next; I advise the Owner who dresses his proper Land, or the conscientious Farmer, not to lay on his Chalk, as is the Custom, alone, but to mix one Load of mellow Chalk with three Load of Dung, and a Load of River Mud, in order to spread upon his Land. This will keep it in heart, as well as give it that pushing Quality: and it will, after the Power of this is over, receive another Dressing of Chalk with the same Benefit as the first, without any Time of Rest.

The chalking of Lands in this Manner, will answer like the marling of them in some Parts of England, where they renew the Dressing once in ten or twelve Years, and keep working the Land from one Generation to another.

The Fault therefore that is charg'd upon Chalk, is rather to be laid at the Door of the Husbandman. There are many Ways of ruining a Piece of Land, and this is one. But the Chalk may be so manag'd, as to enrich it for ever.

I have observed that Chalk does best upon those Lands, which have nothing of it in their own Nature; and that the Farmer generally succeeds best with it, who brings it fartheſt. This must not appear an idle Report, for it is founded on Experience. In Buckinghamshire they bring Chalk from Pits, opened for it in particular Places. In many Parts of Hertfordshire, where the Chalk runs in a thick Bed, at some Depth under the Soil, they dig for it in the Middle of the Field where they intend to use it: Chalk, upon a proper Soil, will do great Service any where. But I have found, by a careful Observation, that although of great Service in both these Counties, it is of much the greatest in the former.

The Quantity of Chalk laid on in these different Places, may also shew that it takes much more Effect in Buckinghamshire, where it does not lie under the Land on which it is laid, than in Hertfordshire where it does: for the Farmers are always guided in their Quantity of Manures by Experience. In Buckinghamshire they lay fourteen Load of Chalk upon an Acre; in Hertfordshire the common Allowance is twenty-five or thirty Load; and the Effect in the former County, allowing the Lands to be the same, is considerably greater, as observed already.

This greater Effect from a smaller Quantity of Chalk, I take to be owing to their not laying a Bed of it under the Soil in Buckinghamshire, for I suppose if there did, the Farmers would not go farther to seek it, any more than their Neighbours. The Soil, it has been shewn already, usually partakes of the Nature of the Beds of Matter that lie under it.

In Hertfordshire the Effect of a good chalking lasts twenty Years, if the Farmer understands his Business, and does not over-work it: in Buckinghamshire, where but about half the Quantity is used, it must be allowed, it does not last above fourteen or fifteen Years: but then the Land, in the former Instance, is ruined; whereas, in the latter, if a little Care has been taken, as directed already, in the first Dressing, it is ready to receive another, with the same Advantage.

The Farmer must dig his Chalk in the Beginning of October, and let it be exposed to the Rains and Frost all the Winter; in Spring it must be beat and spread about, and plowed into the Ground. After this the Corn is to be sown, if Barley, and a fair Allowance of Soot spread over it. This is the common Practice where this Manure is best understood, and the Profit they reap from it is more than can be imagined.

This is the general Rule, but the practical Reader is to suit it to his particular Occasions. If he have a very fine and soft Chalk at hand, he may lay it on immediately from the Pit in Spring. Nay it is the best Method for a Chalk that is so very mellow; for the Sun and Air during the Winter, only exhaust such a Chalk as this; and are not needful for the reducing it to Fineness.

On the contrary, if he can get no other than an hard and stony Kind of Chalk; let him break it tolerably small, and expose it upon a Lay a Year or two before it is plowed up: this will give it Time to soften, so that it may the better mix with the Soil when plowed in; and, at the same Time, the Rains will be washing some Virtue out of it, which will be gradually received into the Land whereon it has lain.

The Use of Chalk is, in a Manner, confined to Arable Lands; but I shall give the Farmer a Piece of Advice, with regard to the laying it on his Pastures; and in this I shall speak from what I have try'd on my own.

The first Year I used Chalk on my Pasture Grounds, I was afraid I had thrown away my Labour, and perhaps many have been discouraged from the Use of it in the same Manner, by a Trial the Effects whereof they did not sufficiently regard. I perceived that my Grass was not a whit the taller or fuller for it; and therefore I at first thought it did no good: but I soon found by my Cattle, and in my Dairy, that Chalk

gives a Body, or Richneſs, and Sweetneſs to the Graſs, though it does not encreaſe the Quantity: my Cattle fatten'd better upon this than I ever knew them upon any Paſture of the ſame Kind without chalking; and I never ſaw ſo rich Milk as I had from the Cows fed upon that Cloſe.

I recommend chalking of Paſture Grounds therefore, from my own Practice and Experience, to every Farmer, as much as laying it on his plow'd Lands: but herein I muſt give him a Word of Advice.

Chalk muſt be very mellow and crumbly before it is laid on a Paſture, otherwiſe it does more harm than good. If it be ever to mellow in its own Nature, it muſt lie a while expoſed to the Weather; and the harder it is, ſo much the longer it muſt lie. In a Word, Chalk is never fit to be laid on Paſture Grounds, till a Man can crumble any Lump of it to Pieces by treading it, or rolling it about a little under his Foot.

In ſome Parts of ENGLAND the Farmers ſpread Chalk upon their Lands, after they have marled them: but this is quite unneceſſary. It is one of the Practices of the antient Huſbandry, and we know how difficult it is to beat the Country People out of the old Tract. It is recommended by MARKHAM, and others of that Time, who always adviſe the mixing many Dreſſings; and often direct every Sort of Manure whatſoever, to be laid one over another upon the ſame Field.

Theſe Writers may often aſſiſt the Farmer; and it would be better for the Country in general, if they were more obſerved than they are: but the Practice of ingenious and induſtrious Perſons ſince their Time has greatly improved the Art of Huſbandry.

CHAP. XVI.

Of the Uſe of Salt as a Manure.

SALT affords the Farmer one of the ſtrongeſt Inſtances of that excellent Rule, that Things may be good in Moderation, though deſtructive in Exceſs. We read of Fields ſown with Salt, in order to make them barren: but we alſo know by Experience and Obſervation; from what we ſee in Nature, and what we are able to effect by Art, that Salt in a due Proportion is a great Cauſe of the Fertility of Land.

Accident, which is as often the Mother of Improvement, as Neceſſity is of Invention, firſt led the Way to the Uſe of this rich and excellent Manure. But it was Accident attended with Obſervation: for without that, Heaven and Earth point out Advantages to Mankind in vain.

There had long prevailed an Opinion, that Salt gave Barrenneſs to Land, and none would ever have diſputed the Fact, much leſs have thought of Salt as a Cauſe of Fertility, but for the Obſervation of what follow'd where Salt had chanc'd to be thrown upon Lands in a moderate Quantity.

In DEVONSHIRE a Piece of plow'd Land happen'd to be overflowed by a Spring Tide, that roſe higher than any other had done in the Memory of Man. The Farmer who rented it at a ſmall Price, had loſt by it every Year: but the Seaſon ſucceeding this Overflowing, he found his Crop ten-fold; though he had uſed no other Methods of dreſſing or preparing that Field than uſual. This was an Accident, the Conſequences of which were ſo plain, every body muſt ſee them. If Salt added to Land by Accident made it fruitful, the Farmers were ſenſible it would have the ſame Effect if added purpoſely with that Intent. On this plain Reaſoning they began the Practice, and it ſucceeded happily.

This was the Introduction of Sea Salt as a Manure in DEVONSHIRE, which is the Place, by all I can learn, where it was firſt uſed in ENGLAND.

WORCESTERSHIRE appears to be the next Part of this Kingdom where it came into Repute, and that alſo from the Obſervation of an Accident, though of another Kind. As in DEVONSHIRE, they were in the Reach of Sea Water, in WORCESTERSHIRE they have Salt Springs. The Water of theſe is a perfect Brine. It is much ſtronger of Salt than Sea Water is any where, and the Salt is of the ſame Kind.

It had been long obſerved in that County, that when this Water dribbled to waſte, the Ground was quite barren over which it ran; but that all about thoſe Places, the Graſs grew much fuller and finer than elſewhere. Upon this they began to uſe Salt, or weak Brine, in moderate Quantities; firſt on their Paſtures, and afterwards on their plow'd Lands; and the Conſequence was, the enriching of them both in a Degree not to be obtained by any other Manure, which they could command in that Part of the Kingdom.

After this, People obſerving the Growths upon thoſe Salt Marſhes that lay at a favourable Diſtance from the Sea, and had the Benefits without the Miſchiefs ariſing from Salt Water, began on comparing them with what was practis'd in the before-mentioned Counties, to underſtand truly the Nature of Salt as a Manure, and have ever ſince uſed it accordingly.

This was the Introduction of that Manure into the Practice of Huſbandry, which has now ſpread very far; and it were to be wiſhed would extend itſelf univerſally.

We find the old Writers on Huſbandry in our own Language, acquainted with the Uſe of Salt much better than thoſe who condemned it at all Adventures, as a Cauſe of Barrenneſs. They underſtood the Advantage of Sea Sand over River or Pit Sand, and they were ſenſible that this was owing to the Salt it contain'd.

On this Principle they proceeded when they adviſed thoſe Farmers who lay too far from the Sea, to have the Advantage of Sea Sand, to ſprinkle Salt upon their Corn Lands. They preſcribe the ſpreading of this in the Manner of Corn, thinly and evenly over the Ground: they call it ſowing of Salt, the Quantity they direct the Farmer to uſe is two Buſhels to an Acre.

One

One Thing farther I muſt obſerve to the Credit of theſe Authors. They all direct Bay Salt, and it is certain that Bay Salt is more of the genuine Nature of Sea Water than any other. This Kind is made by expoſing the Sea Water to the Sun and Winds in ſhallow Pits dug in the Earth: and the common white Salt is made by boiling Sea Water over the Fire. This laſt Method evaporates every Thing that was in the Water, except the Salt and ſtony Matter only; and it is plain enough perceived, becauſe this has no Taſte but Saltneſs: whereas the Bay Salt which has had no other Heat but that of the Sun, has a ſenſible Taſte, and contains more of the natural Principles of the Sea Water. This is plainly diſcovered in eating; and not leſs palpably by its Effect on Land.

The ſteeping of the Grain that is to be ſowed in Brine, is a Practice known all over ENGLAND, and the Advantages of it are well underſtood. Of this more in its Place hereafter; but it is not amiſs to obſerve here, that this Practice confirms the Account, that Salt in Moderation is uſeful to Land. It was a Thing diſcovered by the ſame Means, by perfect Accident. The Loading of a Ship that was caſt away was Wheat: the Wheat was afterwards ſowed, and being ſown, it was found to thrive better than any other.

This ſoon brought into Uſe the ſteeping Seed Corn in Brine, and Practice confirms that it not only makes it grow ſtronger, but prevents Smut.

The Mud out of Salt Water Ditches has been of late brought into Uſe in ESSEX; they mix it with Lime and mellow Chalk, and it makes an excellent Dreſſing for the pooreſt, and moſt barren Lands.

Upon the whole: The Farmer can never do amiſs who uſes Salt in the Deſign of fertilizing his Corn Lands, except he uſe too much. Moderation is the great Rule of Life: he that can't practiſe it will thrive in nothing. I would adviſe in the firſt bringing barren Lands to Fruitfulneſs, to uſe at leaſt three Buſhels to an Acre: aftewards one Buſhel to an Acre is ſufficient. It ſuits all Soils whatſoever, and the beſt Time of laying it on is with the Corn in ſowing; for the firſt Rain thoroughly diſſolves it: it then penetrates the Surface, and is of Uſe to the Shoot as ſoon as it is made.

CHAP. XVII.

Of the Uſe of Sea Weeds as Manure.

WE have not yet done with the immediate Products of Nature as Manures. I would have the Farmer perfectly acquainted with the Effect of every Thing that has been, or that reaſonably may be uſed for this Purpoſe: for on theſe more than on any Thing, next to his Induſtry, depends his Succeſs.

The Uſe of Sea Weed is confined to thoſe Parts of the Kingdom which are near the Sea Coaſt, for it muſt be uſed in ſome Quantity: but it is an Advantage too many neglect, who have it thrown as it were into their Mouths: and few that can be offered, are greater.

The Uſe and Value of Sea Weeds as Manure, depend upon the plaineſt Principle in the World. All Vegetables whatſoever are rich Manures when in a State of Decay: Salt we have alſo ſeen is a very rich Dreſſing: now Sea Weeds have the double Advantage of their own Vegetable Nature, and of the Sea Water in which they grow.

Nay, there is ſomething yet more than this in favour of their Richneſs. Curious Perſons who have examined them according to Chemiſtry, have found that they contain much the ſame Principles as Animals: and it has ſince that been diſcovered by the Help of Glaſſes, that they are always crowded with little Inſects, that live upon their ſlimy Surfaces, or in their little Hollows. This is ſo ſtrongly viſible in many of them, that ſome ingenious Perſons both in ENGLAND and elſewhere, have ſuppoſed them not to grow as Plants, but that they were made by thoſe little Creatures.

Now to conſider the Sea Weeds in this Light, which is conſidering them truly, what a Right have they to the Huſbandman's Regard as a Manure. Firſt, from their Vegetable Nature; for they are really Plants, whatever thoſe Perſons may fancy: in the next Place, from their Saltneſs; and laſtly, and above all, from their Animal Nature; for every Thing of the Animal Kind is rich in fruitful Qualities.

Let us examine by Practice, whether theſe Reaſonings are right; for all the Reaſonings in the World are to be rejected that are not ſupported by Experience and Fact. Let us look into the Places where this Manure is uſed.

In DEVONSHIRE, upon and near the Coaſt, they uſe the Ouze and Mud dragged up wherever they conveniently can get at it, as a Manure. They take this, Weeds and all, and let them rot together, before they ſpread them on the Ground: this is a very rich Manure, but in this Caſe the Benefit is laid to the Mud; the Weeds are not much regarded.

In CORNWALL, where the Shores are ſandy or ſtony, and they cannot have this eaſy Advantage of Salt Water Mud, they tear off the Sea Weeds from the Rocks and Stones; and rake together ſuch as are caſt up by Storms. Theſe they lay upon the Ground without any Preparation, plowing them in, and they enrich it to a ſurprizing Degree.

The firſt Year many of the tough Kinds remain almoſt entire in the Soil; but they give a great deal of Fruitfulneſs to it notwithſtanding: the next they generally break and rot, and they continue nearly equal in point of Fertility that, and the ſucceeding Year.

The firſt Year, the Salt and the little Animals that are about them, fertilize the Ground; the next, and the third, 'tis their own vegetable Subſtance which decays, and enriches the Soil; the ſmaller and tenderer Kinds, the firſt Year, with the leafy Part of the others; and the toughſt, and the remaining Stalks, the laſt.

In ſome Parts of CORNWALL they pile theſe in Heaps, and cover them, that they may rot before they uſe them. This makes them take Effect in a prodigious Manner the firſt Year, but

but they do little the ſecond, and the third leſs. I would adviſe the Farmer to uſe them juſt as he takes them up: for their firſt Effect in this Way is ſufficient to ſatisfy his warmeſt Expectations; and the Benefit laſts longer.

Of all the Manures I ever ſaw uſed, I know none that is ſo quickly ſpent as rotted Sea Weed; but none takes a quicker Effect.

CHAP. XVIII.

Of Sea Shells and their Spawn as a Manure.

THE Farmer who has conſider'd the Nature of ſhelly Sea Sand, as explain'd in its proper Place, will readily imagine that Sea Shells in any State may be uſed as a Manure. They are ſo in moſt Places where they can be had conveniently, and that in different Manners according to their preſent Condition.

Some are taken up freſh on the Shores; others have lain in Heaps expoſed to the Weather: ſome are hard and firm, others ſoft, brittle, and as it were, chalky; and theſe ſeverally require a different Treatment.

Shells in a double Manner have Title to be uſed as a Manure. In the firſt Place, they have belong'd to Animals; and whatſoever has been a part of an Animal, or has any way belonged to one, is ſure to be uſeful to this Purpoſe: in the next Place, they are, after Expoſure to the Air, of a limey Nature, and every one knows how rich a Manure every Kind of Lime is found.

The Shells taken freſh out of the Sea, or from the Shores, have a bright gloſſy Look, eſpecially on their Inſide, and ſhew frequently ſeveral Colours. Thoſe which have lain to be calcined upon the Shores, are all over whitiſh, and have a dead Aſpect, ſo that they are eaſily diſtinguiſhed: they have ſomewhat the Appearance of Lime; and a Calcination by Fire in the common Way, ſoon brings one or other to real Lime.

Theſe are the three Conditions in which we are to conſider Sea Shells as a Manure. 1. The freſh Shells; 2. The Shells that have lain on the Shores till they are calcined by the Sun and Air; 3. Shells calcined by Fire to Lime.

The Farmer is to uſe one or other of theſe according to the Nature of his Ground: the firſt and ſecond are uſually found in the ſame Places, ſo that he has his Choice: and he may make Lime of either at his Pleaſure.

The Progeny or Spawn of Shell Fiſh, is a yet richer Manure than the Shells themſelves. This is found under Rocks, and ſometimes in vaſt Plenty in the Beds of Salt Water Rivers; and is full of diminutive Shells. It diſſolves eaſily: and is ſo great an Enricher of poor Land, that ſcarce any Thing is ſuperior. It is found to be ſo much above Dung, that the Farmers always, where it is to be had, reckon one Load of it equal to three of the other.

When the Ground is poor and heathy, Sea Shells are to be uſed in their natural State: and the freſh and lively Shells are for this Land better than thoſe which have lain expoſed on the Shore till they are bleach'd: but when a tough Soil is to be dreſſed with them, the beſt Way is to calcine them to Lime. If natural Shells are uſed to a ſtiff loamy Soil, thoſe which have lain till bleach'd, are better than the freſh: for they are reduced to a Condition reſembling that of Lime.

No Shells are to be laid on the Ground whole, for in that Caſe they would obſtruct the ſhooting of the Corn, and it would be many Years before they could give out their Virtue. The Farmer muſt break them with Hammers, or in a Mill before he lays them on the Ground, the ſmaller the better: for then the Air takes quick Effect upon them. Moſt Shells are made up of Plates lying one over another, and when the Air can get freely at the Edges of theſe, they ſplit and ſhiver to Pieces; and then give out their Virtue to every Part of the Ground.

I have ſeen the Proof of this in Sussex; where Shells are uſed both Ways. I have taken up a Shell tolerably entire and ſound, that has been laid on the Land three Years, by one who has laid them on whole: and this in all that Time had obſtructed the Growth of the Crops, and given no Virtue, for it was ſtill tolerably firm. Whereas on a neighbouring Farmer's Ground, who had ground his Shell in a Mill before he laid them on, nothing was to be found remaining of them but a few thin Shivers; theſe were as brittle and crumbly as the thin Shells we find in Marle Pits; and doubtleſs they are as rich as thoſe.

Theſe broken Shells had been laid on no longer than the whole ones in the other Man's Field; and I doubt not but in another Year, there was not a Scrap to be found: whereas the others would probably remain whole for the Man's Life.

As the Shells that have lain to be bleach'd on the Shores, fall to Pieces much ſooner than the freſh ones: it may be right where the Nature of the Soil renders Lime improper; and where only freſh ones can be had, to calcine them a little. Half an Hour's gentle Fire will do as much to this Effect, as ſome Years lying upon the Shore: and the hardeſt Oyſterſhells, and the like, may be thus made ſoft and crumbly. They will then eaſily break under the Hammer, or in the Mill, and will diſſolve upon the Ground in a Seaſon or two, though their Effect will be ſeen in the Crop for a great many Years.

Thoſe who have underſtood beſt the Nature of Manures, eſpecially thoſe of the richer Kind, have agreed, that they cauſe the great Fertility which always follows their Uſe by raiſing a Ferment in the Land; and ſo dividing the Lumps, and looſening and mellowing the Soil. If this be the Caſe, as appears very probably, then Experience ſhews, that Sea Shells, properly manag'd, are the richeſt of all Manures, for none looſen and mellow the Earth in ſuch a Manner.

A thorough Dreſſing of Shells enriches the Land for many Years, and indeed too much at firſt; for after a few Seaſons when they are well diſſolved, they make a Soil that was before ſtiff, ſo light and looſe, that like the moory Land in Lincolnshire, or the fine black Mould in other Places, it is not able to ſupport the Roots

of the Corn. In this Caſe the Farmer is to lay it down for Graſs for a couple of Years, and then plow it again. It bears excellent ſweet Graſs in the Time it is lay'd down, and afterwards has Body enough to ſupport a Crop of Corn which before it could not.

The Allowance in general where they can be had in Plenty, is twenty Loads of Shells to an Acre: when they are burnt to Lime they take Effect the moſt ſuddenly, but it does not laſt long. When they are calcin'd a little ſo as to make them crumbly, they affect the Land gradually, and their Virtue will laſt very well twelve or fourteen Years: when they are uſed in their natural Condition, the Effect is ſlower: thoſe which have lain expos'd till they are bleach'd, exert themſelves quicker than the freſh ones; and theſe laſt, as before obſerv'd on ſome Lands hardly ever take Effect at all.

My Advice to the Farmer is always to uſe this Method of half burning the Shells, unleſs upon thoſe barren and cold Soils where they do beſt as Lime: the other Way they take Effect too ſlowly, and in this Manner, though ſpeedy, they are laſting enough in Reaſon.

In Cornwall they uſe the bleach'd Shells moſtly, and their Effect is very ſtrong for ten or twelve Years; in Devonshire they have principally ſofter and brittler Shells than in Cornwall, as ſmall Cockles and Razor Shells: they ſpread theſe as they find them, and they do very well. Abont Plymouth the Shells are moſtly of the Muſcle, and other thin Kinds, and they uſe them freſh as they find them, only breaking them with an Iron Stamper, and they do well enough; but in all theſe Places they would anſwer a great deal better with a little Calcination.

In Ireland they uſe the freſh Shells from Lough Foil, or the Bay of Londonderry, beſtowing fourſcore Barrels on an Acre, and the Archbiſhop of Dublin has given a ſurprizing Acccount of their Fertility; which is publiſh'd in the Philoſophical Tranſactions. He alſo obſerves their Effect in hollowing and looſening the Ground in the particular Manner already mention'd.

The Advantage that the Farmers about our Sea Coaſts in ſome Places, make by this Shell Manure is ſo great, that I hope nothing is wanting to tempt all thoſe who are within the Reach of it, to uſe it. I have ſeen this as well as the other Benefits offer'd by Nature, neglected ſo often, that I think too much cannot be ſaid to ſpirit up the Farmer to employ them. Of this I am ſure, more cannot eaſily be ſaid in their Favour than is true.

CHAP. XIX.

Of Parts of Trees and Plants uſed as Manure.

IT has been obſerv'd in a general Way already, that all vegetable Matter when it rots and decays, becomes a Manure greatly enriching Land, and feeding the Crop that is ſown upon it. In this Chapter I ſhall for the farther Aſſiſtance of the practical Huſbandman, mention the ſeveral Particulars which are moſt ready and moſt uſeful in this Kind.

All large Weeds are excellent to mix with Dung in the Yard, or in a Pit, as already mention'd; and the moſt juicy are the beſt. They muſt be cut up before they run to Seed; and the more perfectly they are rotted, the richer they prove, and the readier for the Farmer's Purpoſe.

Dead Wood, which is found in ſome Quantity in Foreſts, and is ſo rotten that it will ſnap, and almoſt crumble between the Fingers, is an excellent Manure. The Branches of Trees that lie cover'd with Leaves, and the decay'd Stumps of others that are reduc'd to a blackiſh Matter, which is light and ſpungy like Touch-wood, which are not uncommon in damp Places, ſhould be collected by the careful Farmer for this Purpoſe.

I have never ſeen theſe uſed alone except in Lincolnshire, where I ſaw a Piece of Corn Land upon the Edge of the Fens, manur'd with decay'd Willow Stumps beat to Pieces with a Beetle: but about Charlton Forest in Sussex, the Farmers buy the rotten Branches of the Trees, as before mention'd, of poor People, who pick them out of the lower Parts of the Foreſt, and mix them with their Dung.

The Sussex Farmers agree, that nothing enriches their Soil ſo much as theſe dead Branches; and I am a Witneſs in the other Inſtance, that rotten Willow Wood alone is a prodigious Improver of Land, for I ſaw the Crop, which was a very fine one, though the Land was naturally but indifferent.

The Farmer ſhould at leiſure Times employ his People in getting together Weeds and decay'd Wood to add to his Dung, if it were only to encreaſe the Quantity; for there is hardly an Article of more Concern to him in all his Buſineſs, than the making up enough of his Manure. But beſide the Advantage of encreaſing the Quantity, theſe Things certainly add to the Richneſs; and that for two Reaſons: as decay'd Vegetables are themſelves a very fine Manure; and as a Mixture of Manures of theſe Kinds always adds to the Strength of both.

The decay'd Leaves of Trees are worth his Regard alſo: they add but little to the Quantity, but they very much enrich the whole.

The Barks of Trees are as ſerviceable for Manure as any other Part, and their Virtue laſts longer. Not only the naturally rotted Bark is excellent for this Purpoſe; but that which has been uſed by Tanners: this give a very great Fertility, and its Effect will continue ſeveral Years.

Wood that is any Way brought to a State of Decay, will equally anſwer the Farmers Purpoſe. For this Reaſon Saw Duſt is always uſeful; for a little Wet, or a ſhort Effect of the Weather perfectly decays it; and the Effect is more ſpeedy than that of Tanner's Bark; but it is not ſo laſting. Malt Duſt; and Oil Cakes are alſo uſeful in the ſame Way; and when the Farmer can get them, he never ſhould neglect the Opportunity.

It depends upon Accidents whether the Farmer can have theſe laſt mention'd Articles in any Quantity; but whereſoever they fall in his Way, they are a great Benefit, and he knows little of his own Intereſt if he neglects them.

CHAP. XX.

Of Parts of Animals uſed as Manure.

FROM the Parts of Plants we naturally come to thoſe of Animals: all which, as they are of a rich and fertilizing Nature, deſerve the Farmers Regard as Manure. A proper Attention has been ſhewn to ſeveral of theſe of late; and many Things never before thought of, have been introduced as Manures, eſpecially in the Neighbourhood of London.

Indeed the Convenience of having Manures of particular Kinds, is a very great Article; ſome fall in the Way of one, ſome of another; but he who would make the beſt of his Land, muſt have a thorough Knowledge of all the Kinds, that he may take what he can procure: and in this never let him concern himſelf whether the Thing have ever been uſed by his Forefathers, or their Neighbours. For what is good Manure in Kent, is ſure to be the ſame in Somerſetſhire, or elſewhere, provided it be applied to the ſame Kind of Land.

In particular as he will here ſee a Detail of a great many Parts of Animals, which are in different Places uſed as Manure, let him lay hold of any that he can, though never uſed in that Country before. Nay farther, as he finds ſo many different Parts of Anima's are uſed, let him in general be ſenſible that any other may. He may be aſſur'd, that every Thing of the Animal Kind will enrich his Land; and therefore let him freely uſe any that falls in his Way, for whatever it be, he may reſt aſſur'd of Succeſs.

He will find that whether Chance or Judgment directed People at firſt, they do in all Places uſe as Manure ſuch Animal Subſtances as come in their Reach; and let him do the ſame, whether any others have done it or no.

Upon the Coaſts of Norway they dreſs their Land with the Refuſe of the Fiſhermens Boats, who cure great Quantities of Cod and Herring for Exportation. In Newfoundland they do the ſame: and in both Places the Succeſs is very great, no one Thing in all the Liſt of Manures being richer. Theſe People have not learn'd of one another: but Accident, or Knowledge of the Nature of Things, has inſtructed both. Let the Farmer who lives in the Way of this Manure, from theſe Inſtances know its Value. Perhaps one of the Advantages of the preſent nobly eſtabliſh'd Herring Fiſhery, may be the enriching ſome of the worſt Lands in theſe Kingdoms by means of this Refuſe.

The Farmer who lives in the Neighbourhood of a large Market Town, may with great Profit traffick with the Butchers, and all other Perſons who can furniſh him with the Refuſe and Offal of Oxen, Sheep, and other Animals; the Blood, Hair, and every other Kind of rejected Matters being rich for his Purpoſe.

Wool-nippings, the Refuſe of Rabbits Skins, call'd Coney Clippings, and the Hair of any Creature whatſoever, are fine Manures.

Theſe laſt named Articles are of that Kind that do not give a very laſting Richneſs, though great for the Time. The Farmers in many Counties, however, know the Value of them ſo well, that though their Virtue is quite ſpent in a couple of Years, they find it worth while to buy them at ſeven, eight, and ſometimes nine Shillings a Buſhel.

The Way of uſing theſe is to ſpread them thinly and evenly over the Ground, at the Rate of about thirty Buſhels to the Acre. The firſt Rains waſh in their Virtue. And the Crop ſufficiently ſhews its Excellency.

Next to the Hair it may be proper to mention the Hoofs of Cattle, and other tough Parts, which may be had as Refuſe. No matter what Creature they belong to, they are all equal in Riches.

The old Writers on Huſbandry ſay the Farmer is to uſe only the Hoofs of ſuch Creatures as chew the Cud; but that is an idle Fancy, all Hoofs are of the ſame Efficacy, and the only Difference is, that the thinneſt, and thoſe of the youngeſt Animals enrich the Ground the quickeſt, and the thicker and tougher have the more durable Effect: though they are all very laſting Manures.

The beſt Way of uſing theſe is to ſpread them upon the Land, ſome Time before plowing, that the Weather may diſpoſe them to part with their rich Parts; they are then to be plowed in, and the Land will have the Advantage of them fifteen or twenty Years.

Theſe Manures agree with all Sorts of Soils.

The Horns of Cattle are too tough and cumberſome to be laid upon the Land, in their natural Condition, but they have the ſame enriching Quality. Shavings of them are to be had at the Horners and Lanthorn-makers in London, and theſe are ſo thin that the Weather is able to affect them. The Hertfordshire Farmers are well enough acquainted with the Value of theſe Shavings, and where to get them. Though they pay a large Price for them, they go a great Way, and laſt a great while, ſo that it anſwers very well.

The Way of uſing theſe is to ſtrew them thinly and evenly over the Land, and after a Time plow them in; they mellow the Earth gradually, and encreaſe the Produce in a Manner that is ſurpriſing.

CHAP. XXI.

Of Dung in general, as a Manure.

HAVING, in the laſt Chapter, treated of the Parts of Animals, as they may be made uſeful in the Improvement of Land; we naturally come next to their Excrements, or Dung; which furniſhes the great ſtanding Article of Manure throughout the Kingdom.

However ſenſible the Farmer may be of the general Uſe of Dung already, there is a great deal to be ſaid of the particular Kinds; and their diſtinct

distinct and separate Uses: for there is as much Difference between one Dung and another, as between Chalk and Marle, or many others of those already mentioned: and there requires as nice a Judgment in suiting the Kind to the Soil; and in the proper Time and Manner of using it, as in any Branch of Husbandry.

The Dung of different Creatures, though it be all rich and valuable to the Farmer, yet is rich in different Degrees; and suited, according to its Kinds, to different Purposes. I shall endeavour to inform the Farmer thoroughly in this Article of his Profession, under its distinct Heads. But first, it may not be amiss to give him some general Notion of the Nature of this capital Manure, and the Manner wherein it enriches or operates upon the Land.

And first, the very Purpose of all plowing and all manuring of Land, is to divide and break the Body of the Soil, which is, in most Kinds, naturally too compact: for the more the Body of the Soil is broke and divided, the more free Passage the Roots of Plants have; and the more they have the Advantage of it.

In plowing, this breaking and dividing of the Body of the Land, is done altogether by Labour; but in the Use of Dung it is done by a Kind of Fermentation. We know that all Dung is naturally disposed to ferment; and we are sensible also, from Experience, that what is liable to ferment of itself, will ferment and work up a large Quantity of any proper Matter among which it is mixed.

We see a little Yeast ferment a great deal of Dough; puffing it up and rendring it lighter: and in the same Manner Dung works up and loosens the Ground. This is what makes the Soil mellow; and this is the natural and real Use of Dung; and the Way in which it makes Land fruitful.

We see an Instance already recited, of the Way in which the Use of Shells mellows the Soil; making it sometimes so loose and crumbly, that it has not Body enough to hold the Roots of the Grain. The same is the Effect of Dung, only more moderate; as we commonly use it: Experience having, in general, guided Men pretty well in the Quantity, though not sufficiently in the Choice.

We may perceive this is the true Use of Dung by this, that Plants of all Kinds grow much better upon Land that has been dung'd; than they will upon an Heap of the Dung itself. So that it is plain the Dung does not directly nourish the Crop itself, but it makes the Earth more fit to nourish it. This is done by breaking and dividing the Earth, and no otherwise.

This may set the Farmer right in one essential Article; that is, the Manner wherein he is to dung his light Soils: of this I shall speak particularly hereafter, but in general, pure Dung, laid upon a sandy Soil has no Effect, because dividing the Soil is not what is there required. The little Stones of which Sand is composed, are not joined together; and Dung has not the Power of breaking or dividing each separate Grain.

Even in the Gardeners Grounds about LONDON, where they force their Herbs to grow, in a Manner, in Dung, we see the bad Effect it has on them. A Gardiner's Turnep has not half the Sweetness of a Field Turnep: and it is well known that the Water which has boil'd one of these Dung Cabbages stinks, whereas there is no ill Smell, but rather a musky Sweetness, in that wherein a Cabbage has been boil'd that has grown in a more natural Soil.

The Farmer will never dung his Fields in that abundant Manner, but if he should, even the Corn would have a Taste of it; this suffices to shew, that the true Use of Dung, as said already, is to fit the Earth to afford Nourishment, in the fullest Manner, to a Crop; and not to yield that Nourishment itself.

But beside this natural Effect in breaking and loosening the Soil, there is another very considerable one in all Dung, when properly laid on the Ground; that is, the giving a Warmth to the Land, and cherishing the young Shoot. This is owing to the same Cause, the Fermentation of the Dung, for that is the Occasion of the Heat it has in itself; and which it so freely communicates to every Thing about it. This may afford a Hint to the Farmer, as to the Time of laying on his Dung, of which more hereafter.

But as Dung thus naturally renders a Soil warmer than it would otherwise be, it may also make it colder; and it has been observed, that whole Fields of Wheat have perish'd by Frost on dung'd Lands, when they have liv'd through the Winter on those Lands of the same Soil, that have had no Dung that Year. It is possible this may have arisen from the Cause to which it has been attributed, that is, to the Hollowness of the dung'd Ground in which Water lay about the Roots of the young Corn, and then freezing, kill'd it: But more Observations ought to be made before this be received as an universal Fact.

It must be farther observed, that Mr. TULL is the Person who delivers this Account, and his Prejudice to Dung might carry him too far. He wrote to establish the Use of a particular Kind of Tillage instead of Dung, so that he may be considered as a prejudiced Person. I shall add, on this Occasion, an Observation which the Farmer will do well to carry with him on all others. That is, that we are to read what is written by Persons who propose Systems, with great Allowances for Partiality. Well supported Facts may be received, whoever relates them, but Men may have been blinded by their Prejudices, when they argue from single Experiments of their own. I am sorry to see, the few who have meddled with this Subject since Mr. TULL's Book, all take up his violent Prejudices against Dung. They have considered him as an ingenious, but they should also have considered him as a prejudiced Writer.

Some Lands bear Dung better than others; and in the same Manner certain Soils require particular Kinds; or a proportioned Quantity of that Manure. In this Part of his Business it is that the Farmer wants to be instructed, not as to the Nature of Dung itself, which he full well knows; and which I hope he will continue to esteem his own Way, and as his Fathers used to do, in spite of all the Charge of Folly and Obstinacy brought against him by partial Writers; who, while they accuse

accuſe him of Ignorance, often know much leſs than himſelf.

Let him continue to eſteem Dung the readieſt and moſt univerſal of all Manures, for ſuch it certainly is: and in order to uſe it to the fulleſt Advantage, let him obſerve the Cautions and Directions that will be here laid before him. He may then tell theſe Enemies to Dung, that all the Accidents they lay to the Charge of that Manure, are owing either to a wrong Choice of the Kind, to a wrong Proportion of it to the Land, or a wrong Management of it in preſerving or laying it on. And theſe are the Errors againſt which I ſhall attempt to guard him, by what I have ſeen in my own and others Experience.

To ſay Dung often does Miſchief is to ſay true, but then it is in unſkilful Hands: but to rail at Dung as always hurtful, were to fly in the Face of all Authority, and all Fact; and to reaſon againſt Experience.

I am ſorry to acknowledge this has lately been done by too many, but they are all blameable for it: they have all done it in Favour of ſome other Manures, or of ſome particular Kind of Tillage. This is to write partially. I have already given a very full Account of many, and ſhall, in the ſucceeding Chapters, of all the other Manures; and the ſame of every Kind of Tillage; but doing them Juſtice, let us do Juſtice alſo to this. The preſent Faſhion of railing at this Manure is enough to miſlead half our Farmers.

It is certain that all Soils do not equally require, nor will all equally bear Dung. This Reaſon dictates, and this Experience affirms. For Inſtance, if the Effect of Dung be to divide and to warm the Soil, Reaſon will affirm that it is not ſo needful on thoſe Soils, which are hot and looſe already, as on thoſe which are cold and compact, or tough. And Experience confirms Reaſon: for ſpeaking in general, Dung is not ſo uſeful on ſandy as on clayey Lands.

In the ſame Manner all Times are not proper for the laying it on, nor is every Condition of this Manure proper for every Occaſion. For if Dung be left, when rotten, upon the Surface of the Ground, the Sun and Rains will exhauſt all its Virtue: and, in the ſame Manner, if it be bury'd too freſh, and in too large a Quantity in rich Soils, it will occaſion Weeds.

All this is true; and from this have ariſen the general Complaints and Cautions againſt Dung. But as that Manure is uſeful, in the higheſt Degree, I ſhall, inſtead of condemning it in general, for the Sake of theſe particular Miſtakes which may happen in the Uſe of it, ſhew the Occaſion of thoſe Accidents which ſometimes attend it. I ſhall point out to the practical Farmer, the Soils to which the ſeveral Kinds of Dung are fitted; and the Manner of preſerving, and the Seaſons of applying them: by this Means teaching him how to prepare his Manure for his Soil, that he may reap its Benefit, and eſcape the Misfortunes others ſuffer from its ill Management.

Having thus led the practical Huſbandman through a general Conſideration of Dung, as a Manure, I ſhall treat ſeparately of the particular Kinds.

CHAP. XXII.

Of Horſe Dung.

HORSE Dung, though the Name expreſs but one Thing may be divided into ſeveral Kinds: and it muſt be ſo in Order to give the practical Huſbandman a full Information of the Uſes to which it will ſerve.

The Differences between the Dung of various Animals, which are very great, as will be ſhewn in the ſucceeding Chapters, depend principally upon the Food on which the Creatures live: the Dung of thoſe which feed only on Fleſh being of one Kind, that of thoſe which feed on Herbage only, of another, and that of thoſe Creatures which eat both Kinds, being of a middle Nature between the other two; and ſufficiently different from both. It is natural Dungs ſhould thus differ, becauſe the Office of Digeſtion is of the ſame Kind in all Creatures: ſo that the Matter digeſted muſt make the Difference.

Now tho' Horſes feed altogether on Herbage and Vegetable Products, yet there is a great deal of Difference between the green and moiſt Graſs they eat on Paſtures, and the dry Hay in the Stable. The Corn alſo is another great Article in the making of his Dung: but this is not all the Difference. If we ſpoke only of the Dung pure, and as it is voided, we ſhould eaſily conceive there muſt be theſe Variations; but we generally mean by Horſe Dung, that which is mixed with the Straw or Litter; and we are alſo to conſider it as it may accidentally have other Mixtures.

To come to a perfect Knowledge of this Manure, we are to conſider it then in three Conditions. As picked up pure and entire; as taken out of Stables, and as ſwept and ſhovelled up from the Roads; which laſt, though not a common, is an excellent Practice. In theſe three States we find the Dung pure, mixed with Straw and Urine, or mixed with Urine and Duſt.

Theſe ſingle Circumſtances make a great Difference; but a great deal more is alſo made by the Time when it is uſed, whether that be while it is freſh, or after it has been dropp'd, or lain mixed ſome Time.

To give the Farmer a general Notion of this Difference, pure Dung is moderately warm; Dung from the Stable, when it has got into a Ferment with the Straw and Urine, is hotteſt of all; and the dry Dung of Roads, though it has little Heat, has yet a great deal of Fertility.

There is alſo a vaſt Difference between the Dung of the Stable, (which is the moſt commonly employed) when it is in a State of Fermentation, and when it has gone through that, and is well rotted. In the firſt Condition it is often too rank, and leſs than the uſual Quantity ſhould be given when it is taken at that Time; but when mellow, it has ſufficient Fertility. Of all theſe Accidents and Conſiderations, we hope to give the Reader the Means of judging fully: and we are aſſured that when the ſeveral Conditions of this Manure are better under-

understood, and more regarded, there will be few Complaints of its ill Qualities.

The Phyſicians when they order Horſe Dung as a Medicine, always particularly direct that of Stone Horſes to be uſed. They have Reaſon for what they do; and the Farmer will have the ſame Reaſon for giving the like Preference in his Uſes of it as Manure.

It is not only that Stone Horſes are uſually more vigorous and ſpirited than Mares or Geldings, that makes their Dung preferable: but in general there is a Difference in the feeding; the Stone Horſe being moſt commonly kept up to dry Meat in Stables.

The Dung of any Animal conſiſts of the groſſer Parts of its Food, mix'd with the Juices of the Mouth, and Stomach, and the Gall. It is therefore a Mixture of well ground Vegetable Matter, and Animal Juice, which muſt make it very rich. And it is plain from this, that the ſtronger and heartier the Food, the better and richer will be the Dung.

Therefore the richeſt Horſe Dung is that of Stable-kept Horſes, well fed with Hay and Corn; and this gets great additional Richneſs from the Urine, which in a well-contriv'd Stable mixes among it. The Stable for this Purpoſe ſhould be well paved, that the Moiſture may not ſoak into the Ground, but mix with the Dung and Litter.

It will be found upon a critical Enquiry, that every Thing the Farmer ſees in the Nature and Effects of Dung, agrees with and ſupports this Account. The Dung of Cows is colder than that of Horſes, becauſe Cows in general feed on Graſs: that of Horſes is warmer becauſe of their Hay and Corn, and the Dung of Fowls is the warmeſt of all, becauſe they feed in a Manner on Corn only.

For this Reaſon Horſe Dung is fitteſt for cold Lands, and Cow Dung for hot: and in the ſame Manner, Experience will always confirm right Reaſoning.

The Dung of our own Species is by many extolled beyond all other; and doubtleſs it exceeds all in Strength and Richneſs, becauſe of the Fleſh we eat: and Swine's Dung is alſo extreamly rich, becauſe of the Animal Part of their Food; they eating partly one Kind, and partly another, as it is offered to them.

Notwithſtanding that it has been ſo much a Faſhion of late to rail at Horſe Dung, all own that it has great Effects. The old Writers attribute the Fertility it gives to Lands, to its being of a Nature fit to attract the Nitre of the Air: and Mr. TULL attributes it altogether to its Fermentation, which breaks and divides the Ground: and this Fermentation he ſays is owing to the Salts with which it abounds

Mr. TULL's ſeems the plaineſt Account; but perhaps there is Truth in both. Whatever be the ſecret Cauſe of the Operation of Dung in making Land fruitful, for a Secret it is yet, notwithſtanding all that has been written about it, it is plain from all Accounts, as well as from Experience, that it has ſuch an Effect; and it will become the Farmer to know exactly in what Manner to regulate it to his Occaſions. To this I hope he will be led reaſonably, by

what has been here written of Horſe Dung, which is the Kind that is commonly underſtood by the Word Dung, when uſed generally; and by what has been written of that Manure in general in the preceding Chapter; ſo that after ſuch Preparation, we may advance to the Manner of treating and uſing this Manure.

Horſe Dung may be too poor from its having too much Litter among it; and from its having lain expos'd too long to the Sun and Air. In this Caſe a great Quantity of it is required to anſwer any Purpoſe; and the beſt Way is not to uſe it alone, but to mix it with other Dung, where it may get into a new Fermentation.

It may alſo be too rich, as when the Litter is well proportion'd, the Urine all ſoaked into it, and the Fermentation high. In this Caſe it will occaſion Weeds and Inſects wherever it is laid; it ſhould therefore be tempered with a proper Quantity of Earth well mix'd among it before it is ſpread. This at once encreaſes the Bulk, which is a material Article, and takes off its Rankneſs.

From what I have ſeen in my own Experience, I prefer the mixing of Earths with Dung upon every Occaſion, to the common Method of laying the Dung on alone. I am ſure every Farmer will find the Advantage who will try.

But in this let him take Care to ſuit the Earth he mixes with his Dung, to the Land on which it is to be laid. I have already ſhewn, that one Soil may always be a Manure to another. Let the Huſbandman keep that in his Mind; or turn back to thoſe Pages. He will there find, that if it be a ſandy Soil on which his Dung is to be laid, a clayey Earth is beſt for him to mix with it; and if it be a clayey Soil, a ſandy Earth, and ſo of the reſt. Carefully minding this, he will at the ſame Time, by mixing Earth with his Dung double or treble the Quantity of his Manure, take off the Rankneſs of the Dung, and give a double Dreſſing to the Land; the earthy Part of which will remain in great Effect, long after the Dung has ſpent itſelf.

I know that the common Method is to adviſe the Farmer to mix Waſh, Weeds, and many other Things with his Horſe Dung in the Heap; and to add Earth to Sheep Dung, by laying it under them in the Hovel; as will be obſerved hereafter. But I am for extending the Practice of mixing Earths to both Kinds, for I have found it as uſeful with one as with the other.

Dung in itſelf is too rich for any Soil. I believe Mr. TULL is right in attributing the great Advantage that ariſes from the Uſe of it to its fermenting with the Soil; and I have found by Experience what is very natural to conclude from Reaſon, that it will ſpread this Fermentation farther, by beginning with a little Earth firſt. The Soil that is already mix'd with the Dung, gets into a State of Fermentation before it is laid upon the Ground; and as ſoon as it is plow'd in, that works upon the reſt.

A great deal is to be conſider'd in the keeping and preparing, as well as applying of Horſe Dung. As to the three Kinds already diſtinguiſh'd, the Farmer will find the moſt frequent Uſe for the Stable Dung, or that mix'd with

Litter and Urine. For the others, the Uſe of pure or entire Horſe Dung muſt be on Grounds that require but moderate heating, with the Addition of their Fertility. The Road Dung is to be uſed where Fertility is wanting, and not Heat; for of the latter it has very little.

CHAP. XXIII.

Of Horſe Dung uſed ſingly.

THE Uſe of pure Horſe Dung is in a Manner confined to paſture Grounds; and that of the Roads to Corn Lands of a clayey Soil. On theſe two Heads I have ſome Things to add from my own Practice, which I hope will be the more agreeable to the practical Huſbandman, as they have not been enough regarded by others.

In the firſt Place, as to entire or pure Horſe Dung, I one Year made my Man take up all the Dung they drop'd as they went along, and lay it up in a Place under Cover. When a large Heap of this was collected, I had it crumbled to Pieces and ſtrewed thin over my Meadow and Paſture Grounds, in the fair Hours of a driping Spring; the Rain waſh'd it in, and the Encreaſe and Richneſs of the Graſs was ſurprizing.

The next Experiment I made with it was, by ſtrewing a large Quantity of it over a Field of Corn, in the Manner the Farmers call ſowing of Dung, and as they uſe Pigeons Dung in many Places: but I muſt own this did not at all anſwer my Expectations. I apprehend that its light and dry Nature, where it lay expos'd upon a naked Field, made it loſe all its Virtue without entering the Soil. But I ſet down both the Experiments juſt as they are: that the Farmer may know what it will not do, as well as what it will.

Now as to Horſe Dung taken from Roads, I have experienced that two Ways, and ſhall in the ſame Manner relate the different Effects. I have a Field not far from a Place in the great Road, were the Horſes ſtand to ſtale, and they drop their Dung often in the ſame Place. I have got the Shovelings of this Part of the Highway for my Field two Ways; and the one it was prejudicial, the other very advantageous.

Firſt of all I had it taken up at a dry Time, when it was almoſt all like Duſt. This taſted ſaltiſh, and I could perceive it was a gritty Powder, with a great deal of dry Dung among it, and ſome Remains of the Urine. The Land I laid it on was a cold clayey Soil, and it anſwered in great Perfection. The Grit breaking the Clay, at the ſame Time that the Remains of the Dung, and the Salt of the Urine, warm'd and enrich'd it. At another Time I had it taken up when it was rediſh colour'd, and as ſoft as Pudding. It was ſpread directly over my Land, which was plow'd in upon it, and Rains coming on, the whole Virtue was kept in, and waſh'd into the Soil: but this did great Harm to my Crop, being too ſtrong of the Urine. Many Things aſſiſt the Growth of Plants in a moderate Way, but will deſtroy them in too great a Quantity. From that Time I have kept to the Uſe of the Road Dung tolerably dry, and have always found great Advantage from it. And I have kept my Heaps of pure Dung for my Paſture, moiſten'd by having the Chamber Pots emptied upon them: and I have found this anſwer to my own great Satisfaction, and the Surprize of all the Neighbours.

CHAP. XXIV.

Of Horſe Dung made into Compoſt.

HAVING now done with theſe two Conditions of Horſe Dung, I come to ſpeak of it practically, in the Way wherein it is ordinarily uſed; that is, as mix'd with Litter and Urine: and indeed the more Ingredients are for this Purpoſe mix'd with it, the better. The antient Writers on Huſbandry have laid down a Plan for the improving Horſe Dung in this Manner, which the lateſt have very prudently copied from them.

The Benefit of Dung in the uſual Way, is not owing to the Richneſs of the Excrement of the Horſe alone, but to its State of Ferment with Straw and Urine. Now this Ferment, and this Richneſs, may be both encreas'd: nor is there any one Article in all the Farmer's Practice, that is more neceſſarily to be thoroughly conſi er'd.

The Virtue of Dung may be improved, and preſerved: to both theſe Things the Farmer is to attend. It will be improved by mixing with it all Kinds of Things that have an Animal Tincture, or Vegetable Matter that will rot with it, or that contain any Salt; and it will be preſerv'd by keeping it cover'd.

Markham very properly adviſes the Farmer to pour continually upon his Heap of Dung, all his Beef Broth, Brine, Soap Suds, and the like; by which Means, he ſays, truly, one Load will be worth five; and in general theſe Writers condemn with Juſtice, the naked and expoſed Manner wherein the Dung is kept; by which Means the beſt Part of its Virtue is loſt before it is carried to the Ground.

On theſe Principles the intelligent Farmer will readily follow the prudent and common Advice to keep his Dung cover'd, and to add to it every Thing he can, which will in general give new Virtue, as well as encreaſe the Quantity. I hope to ſhew him how to uſe Dung to twenty Times the common Advantage; and to avoid all the Miſchiefs that frequently happen from its improper Uſe.

Firſt, for the preparing of it according to theſe Principles, let him dig a Pit of Depth and Bigneſs proportion'd to his Quantity of Soil.

This muſt be well paved, and wrought up the Sides, that no Moiſture can get through and arched over at the Top to keep all cloſe; with a Door for taking out and throwing in the Dung. The draining of the Stable and Cowhouſe ſhould run into this Pit, and into it all the Dung and Litter from the Stable is to be thrown; and the Bottom of the Stable and Cowhouſes paved hard, that the Urine may not ſoak

in,

in, but run through the proper Channels into the Pit; and if the Chamber Pots be daily empty'd into it, ſo much the better.

Beſide the Horſe Dung, all the Cow Dung, Hog Dung, and that of all other Kinds, if not enough to be ſav'd alone, or not wanted alone, is to be thrown into this Pit; and all the Refuſe of the Garden, Cabbage Stalks and the like; and the Aſhes from the Kitchen; the Earth cut up in cleaning of Ditches, and the like: and into it ſhould alſo be emptied, the Waſh, Soap Suds, and all other Refuſe. The whole is to be kept of ſuch a Degree of Moiſtneſs as to aſſiſt in the Fermentation, and no more: and thus every Thing will be made uſeful. The whole Spirit of the ſeveral Materials will be kept in, and the Mixture will be mellow'd in a ſurprizing Manner.

Old Markham who laid the Plan of mixing theſe Matters with Dung, ſays, one Load will be equal to five; later Writers ſay, one will be equal to twenty, but the Farmer muſt take Care how he depends too much upon theſe large Promiſes.

I ſhall propoſe to the Farmer upon the foregoing Principles, an Addition to this, which will be of more worth than all. When he has got his Quantity of Dung thus rotten and mellowed, let him throw in at leaſt three Times its full Quantity of Earth. Thus the whole is made four Times what it was, and every Load will be as good as a Load of entire Mixture. Let him not ſpare the Expence or Trouble of mixing the Earth well with the reſt: when that is done, let it lie together about a Week, in which Time it will ferment and mellow, and will then be fit to lay upon his Land to the greateſt poſſible Advatage.

I will not ſay this Compoſt is not ſubject to breed Worms, for all rich and mellow Soils will have them; but it will breed fewer Weeds than any.

CHAP. XXV.

Of the laying on of Dung.

NOW whether it be this, or any other Kind of Dung that is uſed, there is a great deal of Benefit, or Loſs, from the Time and Manner of laying it on the Ground. Some beſide expoſing it to the Weather while in the Heap, let it be ſpread out upon their Lands a Month or two before it is plow'd in: but this is a great Error; for by this Management, the Sun and Air exhauſt almoſt all its Virtue, before it gets into the Ground; ſo that a large Quantity has very little Effect.

Others lay it on in little Heaps, and let it remain ſo a good while before they ſpread it. This is not ſo weak a Practice as the other; but it is throwing away a vaſt deal of the beſt Part of the Virtue.

In Land that has three Plowings for a Corn Crop, the Time of laying on the Dung is juſt before the ſecond Plowing: and in the Way I have advis'd, let it be carried from the Pit after ſix or eight Days mellowing with the Earth: and let it be ſpread as ſoon as it is laid on; and plow'd in as ſoon as it is ſpread. This is the Way to preſerve all its Virtue; and when manag'd this Way, it is amazing to ſee what Effect it takes upon the Soil. And the Farmer will hence know how to uſe it on all plow'd Lands.

When it is for Paſture Grounds, another Method is required. To the Mixture of the Dung and Earth let there be added an equal Quantity of River Mud; and let a Heap of this be cover'd with freſh Turf, that it may ſweat and mellow together. When it is thoroughly mix'd and ſhort, it is to be ſpread thin on the Grounds before Rains, and it will all diſſolve, and be carried in to the Soil in ſuch a Manner, that only a few Straws ſhall remain.

Theſe are the general Rules for the Management of Horſe Dung, whether uſed of itſelf, or made the Foundation of a Compoſt: but general Rules cannot ſuit all Particulars; and that Advice which is uſeful to one Farmer may be injurious to another, unleſs proper Cautions be added.

Thus if the Farmer who uſes Horſe Dung in the common Way, fears Weeds; let him lay it on his Ground when a little cooled. If he want its utmoſt Warmth and Strength, he is to uſe it freſh, and in all its Vigour; and in this Manner his own Prudence will adviſe him on a great Variety of Occaſions, remembring the general Directions.

When Dung is to be laid upon a Summer's Fallow, the proper Time is juſt before the twy Fallow, ſpreading it juſt before the Plowing, that it may be cover'd in, and be buried to mellow the Ground about it till the twy fallowing, when it will be rais'd again, and mix'd by this Care in a due Proportion. The great Misfortune attending the Uſe of Dung is, that it affects only a ſmall Part of the Soil: but this Practice is a Remedy for that, twice the Quantity at leaſt of the Land falling under its Influence, in this Method of uſing it.

CHAP. XXVI.

Of the Virtue and Quantity of Horſe Dung.

WHEN the Farmer who has been us'd to fill up his Field with Weeds by his dunging it, lets that Manure lie till it be rotten before he lays it on, he avoids that Miſchief: but at the ſame Time he loſes a great Part of the Virtue of his Dung. However, the Land that is ſo ready to be over-run with Weeds is rich, and therefore requires the leſs Aſſiſtance: ſo upon the whole this will do. Thus the conſiderate Man is to take a View of the Matter before he judges any Thing.

There is another Fault in Dung which the Farmers in general are leſs aware of, though it happens in the ſame Kind of Lands. When Dung is improperly laid on a rich Soil, it not only promotes the Growth of Weeds, but it makes the Corn itſelf rank in the Stalk, and thin in the Ear. Nothing is ſo eaſy as to do

Miſchief

Miſchief with Dung. In this Caſe mellow Dung, uſed in Moderation, is the right Practice. The Farmer ſhould never lay his Dung on this Kind of Land till it is rotted to mould, and then not more than fifteen Load on the Acre.

'Tis for this Reaſon that old, mellow, and rotten Dung is ſo often mentioned in the preceeding Chapters. It is oftener required than freſh, on many Lands. And for want of this Knowledge, the Farmer who follows, as he thinks, the Practice of his Neighbours, without regarding his Soil, often injures his Land by the great Expence of dunging it improperly: and knowing no other Method of aſſiſting it, he has Recourſe to Dung again, and ſo ruins it entirely.

The Expence of Dung is very great; and the Farmer often fooliſhly makes it much greater than it need be. He thinks if Dung be right, why then the more of it the better: but Dung is a Medicine that kills in an over Doſe. Neither is there any Uſe in encreaſing it, when it does not amount to a miſchievous Quantity: for three Crops will exhauſt the Virtue of any Quantity of Dung whatſoever. Twenty Load to an Acre is the full Proportion that ever need be allowed.

There is no Grain with which freſh Dung ſo well agrees as Barley, it is ſo natural to this that it does better pure than with any Mixture, and it does beſt of all upon an Etch Crop. In the ſucceeding Fallow the Dung will be perfectly mix'd with the Soil, and have Time to ferment with it. After this the Land will be fitter for Wheat than by any other Management whatſoever.

CHAP. XXVII.

Of Cow Dung.

THE ſeveral Dungs have their particular Natures, and ſeveral Uſes, the latter depending on the former. As Horſe Dung is the Manure for cold Lands, Cow Dung is the proper Dreſſing for hot Soils, this is the common Doctrine, and there is ſome Foundation for it in Truth: not but that all Dungs are, according to the Senſe of the Word, hot; only the Degree is different. They all act upon the Soil, by fermenting with it; and theſe Fermentations are always attended with Heat. The Chemiſts mention ſome Fermentations in their Liquors, that are attended with Cold, but none of thoſe in the Dung made with the Soil are of that Nature.

In ſpeaking of Horſe Dung I have already explained the Occaſion of Heat and Coldneſs in the Effect of Dung in general. As the higheſt fed Horſes afford the richeſt and warmeſt Dung from their dry Food and Corn; it is natural, by the ſame Rule, that Cow Dung ſhould be cold in Proportion, becauſe the Creature feeds, in general, upon green Paſturage: yet ſtill, as Dung, it has ſome Heat and Virtue.

Under the common Article of Cow Dung, the Farmer includes that of the Ox, and others of the ſame Species.

The beſt Uſe that can be made of this Dung is, the mixing it into a Compoſt with the Horſe Dung and other Refuſe, as before deſcribed. And though it has leſs Effect than almoſt any other Kind when uſed ſingly, yet nothing enriches a Mixture more. Let me acquaint the Farmer with what I have learnt from Experience.

I have ſaid before that, on many Occaſions, Dung which has lain together till it is mellow and rotted, is better than ſuch as is freſh. This gives a more ſlow but more general Fermentation to the Soil, than hot freſh Dung; and at the ſame Time that it feeds the Corn in the Ear, it keeps down its Rankneſs in the Stalk, and prevents Weeds.

This may ſeem ſtrange to the unexperienced Reader: but the practical Huſbandman knows there are Soils which do this naturally; and others may be made to do the ſame by Art. He ſees ſome Lands on which Barley in particular has an Ear almoſt as long as the Stalk; and he may give the ſame Virtue to others.

This he is to do by manuring a tolerably warm Soil with rotten Compoſt, and the beſt Ingredient in this is Cow or Ox Dung. The Way I have practiſed it is this. I have made up an Heap proportion'd to the Bigneſs of the Field, of Horſe Dung, Cow Dung, and River Mud; laying them in Layers one over another; a Layer of Horſe Dung, then of Mud, then of Cow Dung, then a Layer of Mud, and then of Horſe Dung again, and ſo on. This Heap I cover with freſh cut Turf, and leave it in that Manner to mellow and rot together. When they are thoroughly rotted I mix all well by frequent turning, and then ſpread it over the Land juſt before plowing, that it may be cover'd in, and yield all its Richneſs.

I have met with very few who know the real Value of Cow Dung, and that becauſe its Nature is not thoroughly underſtood. It has not the ſudden Effect that Horſe Dung has, becauſe it does not ferment ſo briſkly: and therefore it has been ſuſpected of having much leſs than it really poſſeſſes. What Virtue it has alſo very freely evaporates, and is loſt if it be uſed without due Care. So that the Method in which I have found it ſo excellent is, perhaps, the only one whereby its full Virtue can be given to Land.

CHAP. XXVIII.

Of Sheeps Dung.

I COME now to treat of one of the moſt valuable Articles in the whole Claſs of Manures: For the Dung of Sheep is, for many Purpoſes, better than any other whatſoever. It has not that violent Heat which is in Horſe Dung, from the high Feeding of the Creature; but there is a Richneſs in it that exceeds almoſt any other.

Sheeps Dung is not to be managed as Horſe Dung is, becauſe of the Smallneſs; but the Farmers have two Ways of uſing it very familiar, and very advantageous: and theſe are employ'd according to the different Occaſions. The one is folding them upon the Land; the other by ſaving the Dung, together with the Urine, under a cover'd Fold. The former is the more ready and the more common Method, but the latter is by much the moſt advantageous: and is what many have laboured very wiſely to encourage.

But beſide the Uſe that is made of Sheeps Dung theſe two Ways, a great deal is loſt, which might be ſaved to great Profit. When the Sheep are fed on Downs they drop their Dung about, and it does very little Service to that Soil. The wiſe Huſbandman may have great Quantities of this daily pick'd up, at very little Charge; and he will find it more valuable than ordinary Dung, by many Degrees. This I mention as a Hint to the induſtrious and prudent, and ſhall now proceed to the two Methods by which Sheep are made to yield their profitable Manure to moſt Advantage.

The Method of folding them upon Lands is ſufficiently known, and when there is a good Flock, well managed this Way, the Advantage is very great. But here let me adviſe the Farmer to take Care, that their Dung be not left expoſed to the Air and Sun, upon the Surface of the Ground, for that will exhauſt its Richneſs with no Value to the Land. The Dung ſhould be plowed in as ſoon as poſſible: for it is, of all Dungs, the moſt free to loſe its Virtue: and I will maintain it, from what I have ſeen, that ſuch Earth as is plowed up immediately after the Fold, while the Dung is yet freſh, and the Earth is moiſt with their Urine, will have ten Times the Benefit of that where the Folly and Careleſneſs of the Farmer leaves it any Time expoſed.

The Richneſs of this Manure depends, in a great Meaſure, upon the Mixture of the Sheeps Urine with the Dung; and this is evaporated preſently by the Sun, if the Earth be not plowed up to mix and bury ſuch Part as is moiſtened by it: and in hot Seaſons the Dung itſelf will, on a little Expoſure to the Sun, be rendered dry, and of very little Value.

The Dungs, in general, ſuit all Kinds of Soils; but a cold Clay is what receives moſt Benefit from the Folding of Sheep. When the Dung is ſaved in the cover'd Fold, of which I ſhall next treat, the Mixture being what the Farmer pleaſes, he may, at his Diſcretion, ſuit it to all Lands, and there is no Soil whatever whereon it will not be uſeful.

This Method of the cover'd Fold has been ſo long propoſed, that it is a Wonder it has not come more generally into uſe. It is familiar, cheap, and eaſy: It yields a vaſt Quantity of Manure, which is a great Conſideration: and the Farmer, as already obſerved, ſuits this to his ſeveral Purpoſes at Pleaſure: the Advantage therefore is univerſal.

The Method of preparing this is delivered by all the old Writers on Huſbandry, and 'tis ſurpriſing that it is not as univerſally practiſed as it is adviſed, for not one of the new ones but has recited it. Our firſt Promoters of it learned it from FLANDERS, where it is ſtill practiſed to the greateſt Advantage; nor is there any thing that more accuſes the Farmers of our Country in general of Backwardneſs in Improvements, than their Neglect of this excellent Method.

Mr. BLITH recommends Sand to be uſed for receiving the Dung and Urine of Sheep in the cover'd Fold; and others have mentioned other particular Kinds of Earth, but any Kind will receive the Enrichment; and therefore the Farmer is to ſuit that to the Purpoſe for which he wants it, uſing Sand, poor Earth, Loam, or whatſoever elſe will beſt agree with his Land, according to the Directions already given on that Head.

The Manner of doing it is this. Let a large Sheep Houſe be built of a long ſquare Shape, boarded at the Sides, thatch'd at the Top, and open at one End. Let there be Cribs put all round it, for fothering the Sheep when neceſſary; and a Crib may be alſo placed in the Middle. Let the Floor of this Sheep Houſe be cover'd a Foot and a half deep, with a ſandy, loamy, or other Earth, according to the Nature of the Land which is to have the Manure, and let the Sheep ſtand to feed, and lie on it.

At a Week's End let a freſh Quantity of Earth, of the ſame Kind with the firſt, be brought in: and the Dung the Sheep have made, cover'd with it: and let this be repeated every Week, each Covering of new Earth being ſpread to the Depth of three or four Inches. The Sheep will thus lie higher and higher every Week, and all the Earth that thus makes their Bed, or the Floor of the Sheep Houſe, will be mellowed and enriched with their Dung, Urine, and the Fatneſs and Perſpiration of their Bodies; in ſuch Manner that the whole will be one of the richeſt Manures the Art of the Farmer can poſſibly procure.

A Part of it may be taken away from Time to Time, as it is wanted, and freſh Earth laid in its Place, ſo that there will be a continual Supply.

This Method may be uſed for the folding of Sheep all the Winter, that are folded open on the Lands in Summer: and thoſe Sheep that are kept on the Downs may be houſed at Nights all the Year round, in the ſame Manner. The Quantity of Manure thus made is vaſtly great; and the Expence almoſt nothing. And we are to add this farther Conſideration, that as ſandy Soils are a Manure for thoſe which are clayey, and ſo of the reſt, the Farmer will all the while that he is enriching them with Dung, be breaking or giving them a Body, or altering them in whatever other neceſſary Way their Kind requires, with the oppoſite-natured Soil, which is carried on with the Dung; and which will never be ſo well mixed with thoſe Lands any other Way. A Courſe of Years manuring the worſt Soil in the World, in this Manner, will thoroughly alter its Nature, ſo that it never can relapſe into its original Barrenneſs again, and the Farmer will be gathering great Crops all the while.

Even the barren Downs may be, in Time, brought to good Land, by the Continuance of ſuch a Practice: and it is no unreaſonable Expectation that a late Author forms, of ſeeing ſuch an Improvement take Place, if the People concern'd can be prevailed with to have theſe cover'd Folds on their Sheep Walks, and to take the Manure as it riſes, for the Improvement of encloſed Pieces of the Land.

CHAP. XXIX.

Of Hogs Dung.

HOGS Dung has been condemned by ſome of the antient Writers; who have been follow'd in their Cenſure by ſome among the later; as unfit for Corn Lands: but the very Nature of that Cenſure will ſhew the reaſonable Huſbandman, that the Manure to which it was applied, deſerved Praiſe. The Fault they attributed to Hogs Dung was, that it produced Weeds. We know that whatever forwards the Growth of one Plant, will promote that of another: and it is our Purpoſe to oppoſe Reaſon and Truth, to Prejudice and Error.

The whole Fact is, that Hogs Dung is a very rich Manure. Any good Dreſſing will forward the Growth of Weeds, if it be laid on in too large a Quantity. Hogs Dung, as it is the Excrement of a Creature that feeds partly on Animal, and partly on Vegetable Food, is, according to the Principles before laid down, richer than that of any Creature can be which feeds on Vegetables only. This Richneſs was underſtood by the antient Huſbandmen as a Fault. Experience ſhews, that one Load of Hogs Dung will go as far as two of the beſt Horſe Dung. The antient Farmers who did not know this, laid it on in the ſame Quantity they did the other, and then condemned it for the Effects of its great Richneſs, becauſe they had not the right Management.

Any Dung will forward the Growth of Weeds when laid too thick; and they always laid Hog's Dung too thick, becauſe they did not know its Virtue.

The Mixture of Hogs Dung and Urine, as before obſerv'd, heightens the Virtue of common Dung extreamly: and this is a very good Way of uſing it; indeed for Corn Lands no Way is better: for it does not mellow ſo well in the Earth, when laid in a Heap, as Horſe Dung does; and it is ſo rich, there is no ſpreading it thin enough ſingly.

But though it cannot be conveniently uſed alone for Corn Lands, there are other Purpoſes for which it ſerves excellently in its entire State: and among theſe I ſhall name one by which it is ſaid to prepare Ground for Corn better than any other Method.

Hogs Dung uſed entire and alone, is excellent on Meadow and Paſture Ground, producing a large, and at the ſame Time a ſweet Blade.

It is alſo preferable to any other Dung whatever for Trees. It has been obſerv'd of old, that Pigeons Dung was the beſt of all others for the Culture of Fig Trees; but I have try'd it with Hogs Dung in a fair Compariſon: and I have found that the Pigeons Dung is uſeful for other Trees as well as the Fig; but that the Hogs Dung is preferable to it both for that, and all other Kinds.

No Dung yields its Virtue ſo readily as Hogs Dung: but then none loſes it ſo quickly by an improper Management. The Time of laying it on ſhould be carefully regarded; for a gentle Rain coming on, will entirely waſh it into the Ground in a few Hours; and, on the other hand, a dry windy Day will carry away all its Efficacy, and the Land will be no better than if it had been ſprinkled with ſo much Chaff.

The Farmer who chuſes to uſe Hogs Dung on his Corn Lands, muſt remember not to ſpread it in a dry Seaſon; and not to lay on too much. He will do well to make it up with other Matters, and ſo at once encreaſe its Quantity, and render it more convenient for Uſe in the Field. This is to be done in this Manner.

Let the Hogſtyes be well paved, that nothing can ſoak into the Ground, but the Dung and Urine together may mix with whatever is thrown in. Then let all the Refuſe of the Garden, Bean Stalks, Peaſe and Bean Cods, dead Plants, and all other Sorts of waſte Matter, be thrown in, and ſtir'd about from Time to Time, that the Dung and Urine may thoroughly mix with the reſt.

The Hogs will be very well pleas'd with this; and it will raiſe a Quantity of Dung twenty Times as great as naturally would be had from the ſame Number of Swine. This is to be cleared away and uſed as there is Occaſion, throwing in freſh Matter to be mix'd with the Dung and Urine, and converted into Dung in the ſame Manner.

I have obſerv'd that in ſome Parts of Kent, they have imitated the Cuſtom of cloſe folding Sheep, in the Management of their Hogs. They lay the Bottom of the Stye deep with Chalk; and after that has received the Dung and Urine for ſome Time, they dig it up and dreſs their Lands with it to great Benefit; laying in a freſh Pavement to be enrich'd in the ſame Manner for ſome ſucceeding Opportunity.

Earth, Sand, and other Materials, may by the prudent Farmer be in the ſame Manner laid in at the Bottom of his Styes, and dug out once in ten Days or a Fortnight; and the Styes again ſupply'd with freſh. This Earth will be vaſtly enrich'd by the Dung, Urine, and Perſpiration of the Creature, and will make an excellent Dreſſing for Lands. The Quantity alſo will this Way become very conſiderable.

In Staffordshire they underſtand the Value of Hogs Dung ſo well, that they will ſow Lands purpoſely to feed them. There is a particular Kind of Pea they keep for this Service. It is a ſmall white Kind. They ſow the pooreſt Lands with this on Purpoſe for their Hogs, turning them in to fatten; and letting them lie Day and Night upon it. By this they have a ſufficient Advantage from the Swine; and at the ſame Time the Land is ſo enrich'd by their Dung, that it will yield a good Graſs many Years.

This has perhaps given the Hint to a late Author, who has not ſet his Name to his Work, for his Propoſal of ſowing Clover for Hogs. He propoſes the keeping a proper Number of Sows that are ready to Farrow, in Styes made in the Corners, and along the Hedges of a young Clover Field. They are to be fed with boil'd Turnips at firſt, and afterwards with raw ones, rais'd for that Purpoſe, till they have farrow'd, and the Clover is of a Height to feed them.

They are then to be turn'd looſe, where they will thrive in a ſurprizing Manner, grazing without rooting up the Ground.

This Practice, the Author ſays, may be followed upon the ſame Land for three Years with great Profit; and at the End of that Time the Land will be ſo enrich'd by their Dung and Urine, that it will yield vaſt Crops of Corn without any other Dreſſing. It is ſtrongly recommended, but we cannot ſay that we have any where ſeen it try'd, it reſts upon the Faith of the Perſon who propoſed it.

CHAP. XXX.

Of Pigeons Dung.

I Come now to a Dung celebrated by all Writers, and valued by all Huſbandmen with the greateſt Reaſon. 'Tis a Misfortune that it is not to be had in much larger Quantities. I have obſerv'd already, that Swines Dung is better for Trees, and from what I have carefully obſerv'd, I believe that is becauſe the Dung of Pigeons is too hot for that particular Purpoſe. But this, which is a Fault on that one Occaſion, is a great Merit on many others.

This particular Heat which it has in a Degree beyond all other Dungs, makes it ſuperior to them all on cold clayey Soils; on which it promotes the Fullneſs of the Ear in Barley and Wheat in a ſurprizing Manner, while the Stalk and Blade of the Corn are not ſeemingly encreaſed by it. I have ſeen a Field on which the Farmer ventured to beſtow a large Dreſſing of Pigeons Dung, where the Barley ſeem'd half Ear. The Stalk was ſhort, firm and ſtubby, and the Blades ſmall and trifling, but the Head ſurprizing in the greateſt Degree.

It is a very dear Manure where the Farmer is to buy it; but then as a little goes a great Way, it will bear Carriage better than any other Kind, when the Farmer cannot get his Dreſſings on the Spot.

The Farmers in HERTFORDSHIRE will give ten pence a Buſhel for it by the Waggon Load, and ſend fifteen or twenty Miles for it into the neighbouring County of BEDFORDSHIRE; and notwithſtanding this great Price, it has anſwer'd extreamly well in the End.

Forty Buſhels of Pigeon's Dung will be ſufficient for an Acre of Land, but there is to be a great deal of Care taken in the laying it on. The beſt Way is to ſprinkle it at top of the Ground immediately after the Barley is ſown, for this is the Corn it favours moſt of all. The firſt Rains in this Caſe waſh it entirely into the Ground; and the Corn as it ſwells and ſoftens for ſhooting, takes it up almoſt wholly, and has the Advantage of its Warmth from the beginning.

Sprinkled in the ſame Manner upon the Land juſt after the ſowing of Wheat, it has alſo an excellent Effect. They call this Manner of ſpreading, ſowing of the Dung; it is to be harrow'd in with the Seed, and its Effect begins immediately with the Shoot. It continues viſibly during the whole Growth, to Ripeneſs; for no Corn ſwells in the Ear like that which has had a bad Dreſſing of Pigeons Dung. But this is all. Its whole Virtue is exhauſted by one Crop, ſo that in this Reſpect it falls much ſhort of Horſe Dung, and the common Compoſts, which enrich the Earth very well for three.

Pigeon's Dung is excellent on moiſt as well as tough Soils. The Farmer depends on the Effect of its Warmth, which anſwers equally on theſe two Occaſions; but it is more frequently uſed on the black Clays than any other Land.

When temper'd with other Dung, it is excellent for Trees: and alone it is ſuperior to all other Manures for a Hop Ground. It enlarges the Hop upon the Plant juſt in the ſame Manner as it does the Ear upon the Corn, and gives it a particular Strength and Spirit.

To cloſe this Chapter I ſhall make two Obſervations. The one is, That as the Value of Pigeons Dung is ſo very great, it is extreamly adviſeable for a Farmer to have a Pigeon-houſe wherever it can be done with Conveniency: the other, that I have found by Experience, Pigeons Dung may be encreaſed in Quantity in the ſame Manner as ſome other Kinds, without impairing its Virtue, provided it be done with Prudence and Moderation.

The Method I have follow'd is this. I have cover'd the Bottom of my Pigeon-houſe three or four Inches with a fine mellow black Mould well ground to Powder; and this when it has been taken out, mix'd with the Dung and other Matters from the Pigeons, and the Sweepings of the Walls, has been a Manure of prodigious Virtue.

There are many Reaſons for the Farmer's having his Dovecoat where he can with any Convenience, as will be mention'd in its Place; but this of their Dung eſpecially, when rightly manag'd, and made the moſt of, is not the leaſt conſiderable.

CHAP. XXXI.

Of the Dung of Poultry.

UNDER this Head I ſhall conſider the Dung of Hens, Turkeys, Geeſe, and whatever other Fowls the Farmer keeps about his Yard. If we were to give heed to all the idle Traditions on this Head, each of theſe Kinds of Dung would demand a particular Chapter, for they are ſaid to be of perfectly different Natures: that of the Gooſe being a Poiſon to Graſs, and the Dung of the Peacock burning up Corn.

A better Syſtem however is at this Time eſtabliſhed: Experience has given the Lye to Tradition, in theſe and ſeveral like Articles; and we find by Trial, that the Dung of all theſe Kinds of Poultry is very nearly the ſame, and all very rich.

I have propoſed mixing Pigeons Dung with Earth in a ſmall Quantity, and I ſhall for a double Reaſon recommend the ſame Practice with that of Poultry in general; and particularly with

with Hens Dung. In the first Place this is as rich, or nearly so, as the Pigeons, and therefore it will bear a small Mixture of Earth as well. Then it is in its Nature so tough and clammy, that it cannot be spread alone upon the Land so regularly as the Pigeons Dung is.

My Custom has therefore been, to have the Dung of my Hens stir'd up with about an equal Quantity of fine rich Mould, which divides and breaks it so well, that it will freely spread like the other, in the Way of sprinkling or sowing.

I must farther add, that I think, from what I have seen, it gives its Virtue better this Way than when used alone. For the little Quantity of Earth that is mix'd with it, being already in a Condition of fermenting, spreads the Effect very freely through the Land; and ferments the whole, when harrowed in, not only more speedily, but more perfectly than when it is used alone.

This is the best and most profitable Use of Hens Dung, and when thus sown, as they call it, upon Corn Lands, just after the sowing of the Corn, it perfectly well answers the Purpose of Pigeons Dung, where that cannot be had.

I have known Farmers who, to break the Clamminess of Hens Dung, mix'd it with Pit Sand, or with Ashes, and then spread it on the Land. This is a Practice recommended in Books; but the mixing it with Mould is much better: for it ferments with the Mould, which I never found it would do with the Ashes at all, and very little with the Sand.

Hens Dung, properly manag'd, is excellent for Pasture and Meadow Grounds, as well as Corn Lands. I am for the Method of breaking its Clamminess with Earth, and sprinkling it by way of sowing, on this Occasion also; but the Earth I have always used, on this Occasion, is a particular Kind.

I take the Opportunity of the Bottom of some old Hay-stack for this Purpose; the Soil is always mellowed by being so long cover'd with the Hay, and a great Quantity of the Seeds are sure to be mix'd among it. This is the Earth I use for mixing with Hens Dung for Pasture Ground, and I give it in a double Quantity.

This Mixture spread properly in Spring upon the Grounds, makes them yield a Growth beyond any thing else whatever. I have observed before, that these Bottoms of Hay-stacks are of great Value for this Purpose: but they are not to be compared to this Mixture with Hens Dung, when used any other Way.

Hens Dung, when used on Corn Lands, does most good of all upon a cold clayey Soil: but it may be used on any.

Bad Consequences have sometimes arisen from the Use of it, when that has been done without Consideration; and hence it has fallen, in some Places, into Disrepute: but every thing that can do good, may, in a foolish Hand, do harm. Thus some ignorant Farmer, taking the Dung from his Hen-house, and scattering it irregularly on a burning Soil, parched up his Crop; but if he had first mixed it with Earth, and then bestowed it regularly; there is no Soil on which it would not have done Service, though more on some than on others.

Hens Dung is not only excellent on Corn and Pasture Grounds, but for Trees. We frequently see those Trees on which they roost exceed all the others of the same Kind and Standing, in the Strength and Bigness of their Shoots: and Mr. Worlidge gives an Account, from his own Knowledge, of a Quince-tree on which the Hens roosted, which, from the Virtue of their Dung drop'd near the Roots, and wash'd in by the Rains, bore always an incredible Quantity of Fruit.

Peacocks and Turkeys Dung is exactly of the same Nature and Virtue with Hens Dung. These several Kinds should be all gathered up together and mixed with Mould, as I have already mentioned, and they will make a Quantity much greater than might be supposed, till try'd; and will be of great Value.

The Dung of Geese, Ducks, and all other Water Fowls, differs in some Degree from that of the Land Kinds already mentioned. The Dung of Ducks is particularly rich, but neither that nor the Gooses are so hot as the Pigeons. I speak from my own often-repeated Experience.

The Dung of Poultry is not so much minded by the Farmers, as it ought to be. And that of Geese is vulgarly supposed to be a Cause of Barrenness, but on the contrary, it is rich in the highest Degree. It is excellent on Corn Lands, and may be laid on any Soil.

As it is difficult to spread it thin enough it may be mix'd like the others with Mould, with which it will ferment gently, and mellow in a surprising Manner. After this it will be all wash'd into the Earth, Mould and all, and will stir up a general soft Ferment, which breaks the Soil excellently.

I have examined very strictly, and I think all the Effects of Dung may be referred, as before observed, to the double Effect of its Fermentation; in dividing and in heating the Ground: and what I have here to add is, that the violent and hasty Fermentations that are occasioned by the Dung of these Fowls used alone, and other such Materials, soon goes off; and the Earth which was made hollow by it falls close again, before the Crop is half grown; whereas, when they are thus mix'd with Earth, and the Fermentation comes on more gradually, it lasts the longer. I have been led to name this Opinion by what I have seen in the Effect of Goose Dung mix'd with Mould; and I am confident that the Warmth and Hollowness of the Ground, occasioned by this Manure, has lasted in a Barley Field from the Time it was lain on, which is just after the sowing, to the very ripening of the Corn in the Ear.

One Caution, however, let me give the Farmer on this Occasion, with respect to his rolling, which will hold good universally: that is, that he never roll the Ground in wet Weather, for it cakes and clods the Soil, as I have seen, and it has prevented the whole Effect of a Goose Dung Dressing, which was never able to recover the Land to Hollowness after such Usage.

Rolling in dry Weather, on the contrary, at the same Time that it smooths the Ground, flattening the several small Clods, bursts and breaks them: and it is now sufficiently known, that

breaking the Soil is of vaſt Uſe in giving Fertility. Even the beſt Dung, with too little plowing and other Tillage, will anſwer very little Purpoſe; and the worſt in the World, with a great deal of turning, will produce Crops not deſpicable, from the repeated Tillage without Manure.

One Thing more let me add, with regard to Gooſe Dung, before I cloſe this Chapter. The greateſt Difficulty attending it, is the getting it together conveniently, and ſpreading it on the Land. Now I would propoſe to ſome bold Farmer, to take the ſame Method with his Geeſe as with his Sheep, folding them, if I may ſo expreſs myſelf, upon the Land.

To explain this exactly and practically, let him turn in his Geeſe upon his Wheat Field in Winter, and ſuffer them to lie upon it till they have eaten it off cloſe to the Ground, which they will readily enough do, being fond of the young Blade. They will leave in return their Dung very plentifully, and well enough ſpread upon the Land, the Froſts and Rains will ſufficiently break and waſh it in; and his Wheat will riſe, in Spring, not at all the worſe for the Croping, and the Earth will be ſo enriched by that excellent Manure, that the Crop muſt feel the Advantage.

I have never try'd this, or known it try'd. It is propoſed therefore, only as an Experiment worth trying, becauſe the Hope of Succeſs from it is founded on Reaſon. There are alſo in Books many Accounts of accidental Advantages obtain'd from the ſame Cauſe, which are ſufficient to lead a conſiderate Perſon to the Attempt.

The old Notion that Gooſe Dung was deſtructive to Graſs, has been found, by Experience, to be utterly falſe and groundleſs. On the contrary, it is ſeen where ever Gooſe Dung is drop'd in a tolerable Quantity, on a Paſture Ground that has any natural Heart, the Graſs riſes finer, richer, and ſweeter than it does from the Uſe of any Manure whatſoever.

This is Experience, and it is vain to oppoſe againſt it the idle Tales of old Tradition. Of this the Farmer may be aſſured, that Gooſe Dung is as good for Paſture as for Corn Lands; and that if he have Convenience of dreſſing them with this Dung, mix'd with the Bottom of an old Hay-ſtack, as before-mentioned of the other, there is no Manure in the World that will yield him a fairer or fuller Crop.

We learn indeed from Experience in other Countries, as well as our own, where the vaſt Numbers of Water Fowl come in the breeding Time, that their Dung is ſo far from hurting Graſs, or from making it injurious to the Cattle that feed on it, as has been idly imagin'd, that nothing produces ſo rich, or ſo wholeſome Paſturage.

Upon the Coaſt of NORWAY there are ſeveral little Iſlands, where theſe Water Fowl ſettle in ſuch vaſt Flocks, at the breeding Time, that the very Surface of the Ground is cover'd with them. Their Eggs, and their Feathers, are a Merchandize for the People of the Neighbourhood; but this is not all they get by their Viſits. As ſoon as they are gone, the Earth that had been cover'd with their Dung begins to ſhoot up a Sward, that is not equal'd any where in the World; and they ſend in Cattle to feed upon it, which though Carrion when put there, are, in a very little Time, fatten'd to Aſtoniſhment.

Some of the SCOTCH Iſlands are yearly viſited in the ſame Manner, by the vaſt Flocks of theſe Birds that come, from none knows whither, to breed there; and the ſame Effect follows, where there is any Depth of Soil. But we are not ſo ready to take Advantage of the Benefits of Nature as our Neighbours; however, on ſome of the like Places in LANCASHIRE, they have the Diſcretion to feed Cattle upon theſe Spots, after they are cover'd with this rich Sward from the Dung of the Fowl; and they find ſo much Profit from it, that 'tis a Wonder the Practice does not extend every where.

CHAP. XXXII.

Of Human Excrement.

THERE is ſomething diſguſtful in the Thought of uſing the Excrements of our own Species for the Dreſſing of Lands, as it is putting them again down our Mouths: but this particular Kind of Dung, is not without its Efficacy; nor muſt we cloſe an Account of Manures of this Kind, without ſaying ſomething of it. There will be no Harm in the Farmers underſtanding its Nature, as to the uſing or not uſing it, that muſt depend upon his Choice.

It has been obſerved already, that the Excrements of all Animals are rich, conſider'd as Manure, according to the Nature of their Food. The higher fed upon the vegetable Kinds, the better; and that the Dung of Fleſh-eating Animals is richeſt of all.

Upon this Account the Excrements of our own Species muſt needs be very rich, as our Food is, in great Part, of the Animal Kind: there is alſo another Reaſon, which is, our drinking fermented Liquors, which never fail to have their Effect afterwards in the fermenting whatſoever they chance to be mix'd among.

The Dung and Urine of all Animals is beſt mix'd together for Manure, and the Spirit that is in the human Urine is well known to the Curious. Chymiſts make a Liquor from it that is as ſharp as Spirit of Hartſhorn.

The famous burning Subſtance which they call Phoſphorus, is alſo made from human Urine; and the Practice of thoſe who have ſucceeded beſt in the making it, ſhews that the Addition of Excrement to the Urine helps the Effect.

I have named thus much to ſhew what vaſt Spirit and Warmth there is in the human Dung. As to its Uſe, as there is ſomething ſo diſtaſteful, not to ſay ſhocking, in the Thought, and as we have every where Manures enough, of one Kind or other, without it, 'tis more decent and better to let it alone. However, it has been and is uſed in ſome Parts of ENGLAND; and in many Places Abroad oftener than is thought.

This is a Practice every where carry'd on clandeſtinely, for nobody would care to buy that Farmer's Corn, who ſhould be known to uſe it: but there are thoſe in ſeveral of our Southern Counties, who, if they thought proper to tell Tales, could ſay a great deal of the Profits riſing from it.

In FLANDERS it is regularly ſold; and profeſſedly and avowedly laid on Corn Lands; and 'tis well known that they uſe it freely in the Vineyards of LANGUEDOC; where it has been employ'd with us, and the Uſe of it known, the Advantage has been known alſo. The Cuſtom, wherever it is us'd to this Purpoſe, is to ſpread it, for a Time, upon a Bed of Mould, and let it be expoſed to the Sun; after this it loſes a great deal of the ill Smell, and of its hot Quality; and is mixed with a larger Quantity of Mould, and then ſpread on the Land.

People are cautious of talking of this; but ſo far as can be collected that is the Practice. Perhaps if it were let into the common Mixture of the Dung Compoſt, it might add to its Virtue: but 'tis not needful there, nor finally with us, on any Occaſion whatſoever.

The Writers on Huſbandry adviſe the Farmer who ſhall chuſe to employ this Manure, to mix Straw with it in the Manner of Litter: but thoſe who have try'd this declare, that it does not ſucceed as is pretended. The Fermentation riſing from the Mixture of Straw, with the Dung of the Horſe, is very ſudden and very great, but the ſame does not follow on mixing it with the human Excrement.

Upon the whole, though a rich Manure, it is a filthy one, and is the leaſt manageable of any whatſoever, and, of all others, the moſt offenſive to the Servants employ'd in ſpreading it, as well as to the Thoughts of thoſe who are to feed upon the Corn that riſes from its Richneſs.

CHAP. XXXIII.

Of Urine.

URINE has naturally been named in the laſt, and ſome other preceeding Chapters, together with the ſeveral Kinds of Dung; with which it is always mix'd by the prudent Farmer; and which it aſſiſts greatly in its Office. However, it may be proper, at the End, to mention its Effects ſingly; and the more, becauſe they may very naturally, and are very generally miſunderſtood.

The Urine of our own Species, as well as of Cattle, is ſeen to turn any Plant brown upon which it frequently falls; and finally to kill it. And from this there grew an early Prejudice againſt it, as an Enemy to the Growth of Plants of all Kinds; and ſome of the antient Huſbandmen were, for that Reaſon, as careful to keep it out of their Dung, as we are to get it mix'd with it at preſent.

But this ſhould have been conſidered, that many Things which, in their natural State, or being uſed alone, are deſtructive of Plants, yet, in a proper Management, promote their Growth in the greateſt and moſt obvious Manner.

Lime alone is not a Soil for Plants, nay it may be made to kill any. Yet nothing gives Fertility to many Kinds of Soil equally with Lime, when properly applied, as has been hinted already, and will be ſhewn more at large hereafter.

In the ſame Manner Salt prevents the Growth of Vegetables, if ſpread thick over the Ground; and will kill them as certainly as Urine, if laid about their Roots, or ſprinkled over them frequently in a ſtrong Brine. The Effect it takes is juſt the ſame with that of Urine, making the Leaves turn brown and fall off, and, at laſt, the whole Plant to periſh. Yet we find Salt, properly uſed, is a great Promoter of the Growth of Plants; and exactly the ſame is the Caſe with Urine. Theſe Things are too violent in their natural and naked Condition, but, when properly ſoften'd by Mixtures, they are excellent.

Urine has alſo another Advantage over many of the other hot Manures, which is, that it is of itſelf, capable of Fermentation: and by this Means becomes quite a different Thing. The Uſe of fermented Urine is not enough known in ENGLAND. In HOLLAND they have found it; and they know it to be one of the richeſt Manures in the World. They are always very careful of the Urine of their Cattle, which they ſometimes let run among the Dung, to aſſiſt its Fermentation, and ſometimes uſe ſingly.

Even Urine, in its natural Condition, is not ſo fatal to Plants as is commonly imagin'd. If it be repeatedly thrown upon them, it will, doubtleſs, kill them; but Experience ſhews, that after it has made them brown or yellow, if no more be thrown on, they will not only recover, but grow much finer than before.

Dung will deſtroy Plants, as well as Urine, if it be pil'd up about them in the Time of its Fermentation; and it will hurt the Growth on many Soils, if laid on in too great Quantity: and Urine, like Dung, will promote their Growth, when it is uſed with Diſcretion and Moderation.

It is better for Corn Land than Paſture: as to its Uſe in the manuring Soils for Trees, 'tis at preſent unknown, but there was a Time in which People were acquainted with it; and they aſſure us it is excellent for this Purpoſe. The antient Writers in Latin, upon Country Affairs, adviſe the frequent Uſe of it; and they direct that it ſhould be old, or long kept Urine, ſo that it is plain they very well knew the Difference between freſh Urine, and ſuch as had been fermented.

An Inſtance which has been mentioned already of a Perſon procuring a vaſt Crop, by dreſſing the Ground with Woollen Rags ſoaked in Urine, is a Proof, at leaſt, that Urine, in a diſcreet and moderate Uſe, is no Enemy to Vegetation: but in the Eye of Reaſon it declares yet more in its Favour: for, probably, the Effect was as much at leaſt owing to the Urine as the Rags.

There has been alſo another Particular mentioned, of the Uſe of the Cleanſings of Roads where Horſes ſtale. This, more than any thing, confirms the Truth of what has been ſaid here concerning it: for it appears, that when theſe Cleanſings were quite wet, and the Urine of the Horſes among them was freſh, rank, and in great Abundance, it did Miſchief: but, on the contrary, when that Matter was dry'd, and the firey Parts of the Urine were evaporated, though its Salts remained, as was plain to the Taſte, it proved of excellent Service, and occaſioned a very happy Growth.

CHAP. XXXIV.

Of Rags.

THINGS that ſerve to no other Purpoſes whatſoever, generally are uſeful to the Farmer as Manure. We have an Inſtance of this in Rags, which when too bad for the Service of Paper-making, uſually fall to the Share of the Farmer. And he has his Advantage even in their Faults on the other Accounts; for the naſtier they are, that is, the dirtier and the more rotten, the better they ſerve him for enriching his Land.

The Reaſon of this is very plain, for their Naſtineſs ariſes from the Perſpiration of the Bodies of thoſe who have worn them; and all Animal Matters are good as Manure. In the other Reſpect, the rottener they are, the more readily they diſſolve with the Weather, and are waſh'd into the Ground.

The Original Reaſon why Linnen Rags ſhould be uſeful, is, in the Nature of their Compoſition; they are made of Vegetable Matter, and it has been ſhewn already, that all Vegetable Matter when it comes to decay, aſſiſts in the Growth of other Vegetables, enriching the Land for that Purpoſe. Now Vegetable Matter can never be in a more perfect State of Decay than when it is rotting from Rags; unleſs we ſhould name old Paper, which has been made of Rags, and which would doubtleſs prove an excellent Manure if it could be had in ſufficient Quantity.

Linnen Rags got into uſe upon this Principle; and they were found to anſwer beyond all Expectation, which was owing to the before mention'd Addition, their Naſtineſs; which being owing to the Sweat of the Perſons who wore them, could not but enrich the Ground greatly.

Theſe dirty and rotten Linnen Rags were what came firſt into the Hands of the Farmer, and are what he ſtill gets; for the cleaner and better Kind go to the Paper-mills, only the Refuſe coming to him. This in general conſiſts of ſuch as have been worn by the pooreſt and miſerableſt People, and conſequently have been as fully as poſſible impregnated from their Bodies.

This is a diſguſtful Matter to conſider as a Manure; that is, as a Subſtance which is to furniſh the Corn we are to eat: but the Farmer finds his Account in it. It is indeed more diſtaſteful, if rightly underſtood, than the Uſe of human Excrements. Whoever ſhall paſs by thoſe Cellars in which Rags are ſorted for the Uſe of the Farmers, will perceive a Smell from their Doors worſe than that of Bog-houſes by many Degrees: it is indeed ſo horrible, that the Wonder is, it does not breed a Peſtilence. But this is all a Proof of the Fruitfulneſs of the Materials; for all this Smell ariſes from the ſame Cauſe that will raiſe a Ferment in the Soil; and as to the Stench itſelf, it is either loſt in the Air, or left behind by the fine Veſſels of the Plant; never getting into the Corn. This is certain, for HERTFORDSHIRE is the County where theſe filthy Things are moſt us'd as Manure, and no Corn is ſweeter than theirs.

After Linnen Rags had been famous many Years, Woollen began to be thought of; and they are at this Time uſed in ſome Places, but not univerſally. Of their Effect when ſteep'd in Urine, I have ſpoken already; but without it they are very rich. Nor is this at all wonderful: for as the Linnen Rags enrich Land as they are of Vegetable Origin, theſe Woollen ones do it as they belong'd originally to an Animal Body, ſuch Things being known to be richer than Vegetables, on this Occaſion.

In thoſe Places where they have got into the Uſe of Woollen Rags, they buy the Refuſe of Taylor's Cuttings; and they find them anſwer very well: but the proper Woollen Rags for the Farmer's Uſe muſt be thoſe to be bought of the Ragmen in LONDON; and this, for the Reaſons given already about Linnen Rags, which hold true more largely here; becauſe they are rotten, and becauſe they are full of Animal Matter from the Perſpiration of thoſe People who have worn them.

I doubt not but Woollen Rags of this Sort, will be found upon Trial, a richer Manure than any Thing of the Kind: and they may be had cheap enough, being of leſs Uſe in any other Reſpect than the others; and for that Reaſon pick'd from them.

Rags are of the Nature of thoſe rich Manures that ſuit all Soils, but thoſe on which they are found moſt beneficial, are the chalky and clayey. They warm, looſen, and enrich beyond moſt Things, and none ſhew more ſpeedy Effects. LONDON is the great Market for them; but the Farmers in the neighbouring Counties often ſend for them thirty or forty Miles, and find good Account in the Expence.

The Way to uſe them is the ſame which they take with Pigeon's Dung, and ſome other of the rich and light Dreſſings. They are to be chop'd very ſmall, and ſprinkled evenly over the Land juſt after the ſowing of the Corn, ſo that they may give their Virtue to it from the very firſt ſhooting.

About five and twenty Buſhel is the Quantity for an Acre.

In the ſame Manner that they uſe Rags in ſome Places, the Farmers in others uſe old Rope, untwiſting and chopping it fine, and then ſprinkling it over the Land. This is ſerviceable as it is the decay'd State of ſome Vegetable Matter; but it is inferior to Rags, becauſe of the Virtue they have got in the wearing. It is reaſonable to ſuppoſe this ſhould be the Caſe, and it is found ſo in Practice.

In ſome Parts of BUCKINGHAMSHIRE, and the neighbouring Counties, they uſe Linnen and Woollen Rags on their binding Soils in a larger Way; not laying them on as a top Dreſſing, but plowing them in as common Manure. In this Caſe they chop them, but not ſo ſmall as for the other Uſe, and ſprinkle them by hand evenly over the Ground, allowing a much larger Quantity than the other Way: they plow them in about Midſummer, and leave them to enrich the Land againſt the Time of ſowing Wheat.

Mr.

Mr. ELLIS ſays, they have of late got this Practice alſo into HERTFORDSHIRE, where they uſe it on Chalk and chalky Loams, allowing five hundred Weight of the Rags to an Acre. This is a more laſting Advantage to the Lands; for the other only ſerves the ſingle Crop over which it is ſown.

The Uſe of Woollen Rags ſeems to have begun in OXFORDSHIRE, where at this Time it is more general than any where elſe in the Kingdom. The Farmers here buy at a ſet Price the Refuſe of the Taylors for this Purpoſe, and it has been a Traffick in the Days of their Anceſtors, ſo far back as they have any Tradition. The Effects are plain enough, altho' not uſing the beſt Kind of Rags, they have them not in the greateſt Degree: and it is aſtoniſhing, that a Manure ſo well known, and ſo beneficial in one County, ſhould not Ages ago have ſpread itſelf from thence alone through every Part of the Kingdom.

BOOK II. PART II.

Of ARTIFICIAL MANURES.

CHAP. XXXV.

Of Lime.

Its various Materials, and the Manner of making it.

THE employing Lime in Huſbandry, has been one of the great Articles of modern Improvement in that Science: and it is now ſo well underſtood, that there is Reaſon to believe, the Uſe of it will ſoon be univerſal. As there is a great deal of Difference between one Kind of Lime and another; and many Niceties to be obſerv'd in the Uſe of it, nothing can be more needful than a regular Account of its Nature and Effects. Lime is one of thoſe Things that are able to do great Good; and in Conſequence it is capable alſo of doing a great deal of Harm in the Hands of the unſkilful. It would be well that every Farmer in ENGLAND were acquainted with the Virtue of Lime; but it is neceſſary at the ſame Time that he perfectly underſtand how it is to be uſed.

In the firſt Place, Lime is of ſeveral Kinds; for it may be made from a great many different Materials; and it partakes of their ſeveral Natures.

Lime may be made of Lime-ſtone, Marble, Chalk, Sea Shells, and many other Things; but the two principal Kinds are thoſe made of Lime-ſtone and Chalk. Theſe differ very much in their Nature; but we cannot ſay properly that either is beſt; for they ſeverally are fitteſt for different Kinds of Lands: the true Knowledge the Farmer ſhould have of theſe Kinds is, to what Purpoſe each is ſuited.

I would adviſe every Huſbandman to burn his own Lime; and for that Purpoſe ſhall give him ſome very eaſy Rules for the Choice of his Materials. In ſome Places he may find both Lime-ſtone and Chalk upon his Ground: he ſhould then make both Kinds; but if only one Sort of Materials can be had, he muſt make amends for that Defect, by a more careful Study of the Way to uſe it.

Chalk every one knows at Sight: of this I ſhall only ſay, that the hardeſt makes the beſt Lime; and this is for the Farmer's Advantage; for the ſoft marly Chalk is fit for his Uſe in its natural Condition, and the harder he can make fit by this Practice of burning it.

Lime-ſtone is much more common than the Farmer may imagine. It is of various Colours, and Degrees of Hardneſs; but inſtead of referring him to the Skillful for chuſing it for him, I ſhall give him one eaſy Method of doing this for himſelf.

Let him take a ſmall Bottle of Aqua Fortis with him when he goes over his Land to look after Lime-ſtone, and let him pour a little of it upon every Stone that looks fit for the Purpoſe; it will hiſs and bubble up when it falls on Lime-ſtone; but it will run off from all others like Water. This the Farmer may depend upon as an infallible Rule, that every Stone which make Aqua Fortis bubble, is fit for Lime; and no Stone but what does, will ever make Lime freely, or fit for his Uſe.

Having thus found what Materials his Land affords for this excellent Manure, let him build his Kiln for preparing it. This is beſt done in a ſquare Hole dug for that Purpoſe in the Ground, in ſome waſte Place that lies conveniently for the Materials. The Kiln is to be in Shape like a Funnel, wide at Top and narrower all the Way to the Bottom. It muſt be firmly built, and lin'd on the Inſide with a Wall of Lime-ſtone.

Toward the Bottom of this Kiln there is to be a Hole to let out the Aſhes of the Fuel: and above this there muſt be an Iron Grate on which to lay the firſt Parcel of the Materials. Some ſupply the Place of a Grate by an Arch-work of Stone, the ſame with the Lining of the Kiln, but the Grate is very much the beſt Method.

When the Kiln is thus prepared, the Farmer is to get together in two Parcels, his Materials for the Lime, whether that be Chalk or Stone; and his Fuel.

This Fuel he may ſuit to his beſt Convenience, for almoſt any Thing that will burn will do. Coals or Wood ſerve equally well: or very good Lime may be made with Furze Buſhes, Peat, or Fern; which laſt, though ſo light a Weed, burns with a ſurprizing Force.

When all is ready, he is to begin by laying a Layer of the Stone or Chalk looſely upon the

Grate, and over that a Layer of Fuel: thus he is to continue putting a Layer of one, and a Layer of another, till the Kiln is quite full, taking care that the uppermoſt Layer be of the Fuel, not of the Stone or Chalk.

All being thus prepared, Fire is to be given to the Fuel at the Aſh-hole, and it is to be left to burn up, and the Lime will be made of itſelf, without farther Trouble. This is the general Method.

As to the Quantity of Fuel, a Hundred of three Foot Faggots will burn forty Buſhel of Chalk. If Sea-coal be uſed, ten Buſhel will ſtand for the Hundred of Faggots; and the Lime will be made in four and twenty Hours.

Lime-ſtone, according to its Hardneſs, takes more Time, and a larger Quantity of Fuel; but, in general, it anſwers very well to the Expence; being, on moſt Occaſions, very much preferable to the Lime that is made of Chalk.

As to the Quantity of the Lime, Chalk loſes about one third of its Bulk in burning; Stone loſes alſo in Proportion; thirty Buſhels of Chalk make twenty of good Lime, and ſo in Proportion, according to the Nature of the Stone.

Where Chippings of Marble can be had, they make the fineſt and richeſt Lime for Manure in the World: but theſe can ſeldom be in the Farmer's Reach.

In DERBYSHIRE they throw out, among the Refuſe of the Lead Mines, a Kind of ſhining Stone, which they call Spar. It looks ſomewhat like Cryſtal, only not ſo clear: or like large Lumps of Bay Salt. It is whitiſh or browniſh, or of other Colours, and ſome of it that riſes in ſquare Lumps is uſed for ornamenting of Grottoes. This is an excellent Stone for the making of Lime. They burn it wherever it is to be had, and dreſs their barreneſt Lime-ſtone Lands with it: they find one Buſhel of this Lime as good as two of any other Kind whatſoever.

The ſofteſt Kind of Chalks, and ſome Sorts of Marle, may be alſo burnt to Lime with great Profit. As to the Marle, one Buſhel of it in Lime, is of equal Virtue with five in the common Way: and in the Choice of what Kind to uſe, the Farmer muſt have Recourſe to his Aqua Fortis, ſome will ferment and riſe in Bubbles with it, and ſome will not. That which ferments is fit for Lime, and the other is not.

Theſe ſoft Subſtances are beſt burnt with Fern, or other light Firing, and eighteen Hours generally bring them to Lime.

We will now ſuppoſe the Farmer in Poſſeſſion of his Lime; he is to conſider next in what Manner, and on what Sorts of Soils, he is to uſe it.

CHAP. XXXVI.

Of the Manner of uſing Lime as a Manure.

LIME is not one of thoſe univerſal Manures, which do equally well on all Soils. Its Effects are very great, but they are limitted. In general it does well on all light and dry Lands, but does not ſucceed on heavy and moiſt Grounds.

All ſandy, gravelly, and ſtony Grounds are improved in a ſurprizing Manner by Lime: but Clays get very little good by it. Many of the moſt barren Tracts of Land in this Kingdom, are of the ſandy Kind; and Lime has been uſed with ſuch Succeſs as an Improver on many of theſe, that it is ſurprizing it has not been try'd every where.

There is no ſaying what Fortunes might be made by encloſing heathy Grounds, and dreſſing them with Lime; but Huſbandry is not yet an univerſal Science; he who ſhall make it ſo will do more Service to his Country than all her Generals and Commanders, ſince the Time of her becoming a Nation.

Inſtances might be produced of Lands, at this Time, letting for the full Price of the beſt in their Neighbourhood, which fourſcore Years ago would not bring half a Crown an Acre; and the Beginning of theſe Improvements has been by Lime, which has alone rais'd Crops upon them at once, as good as thoſe on the moſt improved Fields.

The common Cuſtom is to uſe Lime alone, but from what I have ſeen, I ſhall venture to affirm, that it takes greater Effects when mix'd with other Matters. This is a Way of uſing Lime that will turn greatly to the Farmer's Advantage.

There have been thoſe who have ſent for Lime many Miles by Waggon Loads, and have found it anſwer very well: but in this there is a double Diſadvantage; not only the Price is greater, but the Lime is certainly the worſe. For when Lime is uſed alone, the beſt Way is to take it hot from the Kiln, in which Caſe the Land has all its Virtue. The Part which is loſt in keeping, is the beſt of all. This ſhould always be the Practice upon the moſt barren and deſperate Lands: for others it does very well a little cool'd, and in Mixtures.

The Way of uſing Lime alone, to the greateſt Advantage of all, is by laying it, in a proper Manner, on the Lands ſometime before it is intended to plow them up; and this I would adviſe to be done in the following Manner.

Let the Lime be carried hot from the Kiln, in the Quantity of about an hundred and fifty Buſhels to an Acre. Let it be laid in ſmall Heaps, and each of theſe cover'd with Earth. In this Manner let it remain to receive the Dews and Showers, till thoroughly ſlak'd: it will then eaſily mix with the Earth, and may be conveniently ſpread and plowed in.

This, though it appear a Way of uſing the Lime alone, really has the Advantage of a Mixture, which incorporates better with the Ground, than it ever would do alone. But in the plaineſt Way of uſing it ſingly, it does more than any other Manure whatſoever.

Stone Lime, ſprinkled over a bare Piece of poor, ſandy, barren Ground, and left to ſlake, will render it fruitful without any farther Care or Trouble, nothing need be done but the common Plowings and Sowing, and there will be a Crop: but not ſo large as if the ſame had Lime been uſed with better Management.

Stone Lime is the beſt for Gravels and ſtony Soils: Chalk Lime does better on the looſe barren Waſtes, where there is only Sand and a poor

Earth. And on light Soils that have ſome Heart, or ſome good Mould among them, the beſt Kind of all is that made by a ſlight burning of the ſofteſt Chalk, or of the chalkey Marles before deſcribed; or that light Kind of Lime which they make in ſome Places, of broken Chalk wetted and moulded like Bricks.

This is what Experience ſhews of the ſuiting the different Limes to different Soils; and the Farmer ſhould attend carefully to it: for by obſerving it he may reap at leaſt double the Advantage that he could from a random and inconſiderate Uſe of this Manure.

Nature, in this Reſpect, is kind to the Farmer, as in many others, if he will but lay hold of the Advantages ſhe offers. Where there is a ſtony Soil that requires Stone Lime for its Improvement, he will commonly find Lime Stone for the making it, ready at hand.

I now come to ſpeak of the ſeveral Mixtures that may be made with Lime, for the uſing it to moſt Advantage, and theſe are three; 1. Dung; 2. Mould or Mud; and 3. Aſhes. Of all theſe Trials have been made, and the Succeſs that has followed, ſhould encourage the prudent and ſpirited Huſbandman to imitate them.

For a very barren ſandy Soil, although Lime alone will anſwer well, yet Experience ſhews the very beſt Manure is a Compoſt of Lime and Cow Dung. The Cow Dung ſhould be double the Quantity of the Lime: it muſt be mix'd with it hot from the Kiln, and then laid up in Heaps, cover'd with a thin Cruſt of the Soil par'd from the Surface. Let this be done a Year before the Ground is broken up. But as ſoon as the Rains and Dews have thoroughly ſlack'd the Lime, let the Heaps be broken, and after mixing thoroughly the Lime, Dung, and Earth, let the whole be ſpread as even as poſſibly over the Land. The Produce upon plowing at a proper Seaſon will be very great, and the Ground will have a more laſting Benefit, than it would have received from Lime alone.

Some have mixed Horſe Dung with Lime, and dreſs'd their light Soils with it; and it has ſucceeded very well, but Experience ſhews Cow Dung is better.

For a dry gravelly Soil that is lean or hungry, the beſt Way of uſing Lime is, mix'd with fine black Mould or River Mud.

If Mould be uſed there ſhould be four Times the Quantity of the Lime, if it be Mud three Times as much is ſufficient: but let the Farmer always obſerve, that if he uſe Mud it muſt not be freſh from the River, for that would ſlack the Lime too ſuddenly; but ſuch as has lain ſpread out, 'till it is crack'd on the Surface, and tolerably dry. Either Mixture is excellent, giving a laſting Heart to ſuch Land, as well as the Warmth and Spirit for the preſent Crop.

For a moſſy Ground the beſt Way of uſing it is with Aſhes; and no Aſhes are ſo good for this Purpoſe, as thoſe of the Land itſelf. The beſt Way of doing it is thus.

If the Land be very ſedgy, as ſuch Ground often is, ſet Fire to the dry Stuff on the Surface, and let it take its own Time to burn. This will often burn away two or three Inches of the Soil, ſometimes a great deal more, leaving the Aſhes ſpread very evenly and well. The Lime is then to be ſprinkled over theſe Aſhes, about an Hundred Buſhels to the Acre, and all plowed in.

If the Surface will not burn, the Turf muſt be pared off, as will be directed hereafter, under the Head of Burnbaiting; and the Aſhes, after the Turf has been burnt, are to be mix'd with Lime, and plowed in as before. In either Caſe the Mixture of the Lime and Aſhes takes an Effect much greater than either could have done alone; and the worſt Kind of moſſy Land will be thus improved, to ſuch a Degree, that a firſt Crop ſhall pay all the Expence of Dreſſing and Encloſure. Of this there are indiſputable Inſtances upon Record.

With reſpect to the Time which the Benefit ariſing from Lime laſts, there is great Difference from the Nature of the Soil, of the Lime itſelf, and from the Manner of uſing it. One great Complaint is, that Lime is expenſive, and that its Good is not laſting: but this may be remedy'd both Ways, by due Care and Management, added to a Knowledge of the Buſineſs.

In the firſt Place, a great deal of the Expence of Lime may be ſaved, as the Farmer is now taught to find the Materials, and burn it for himſelf; and in the next, the Benefit ariſing to Lands from its Uſe may be made much more laſting, by the proper Mixtures and Management; and by a proper Care of the Land itſelf.

The worſt managed dreſſing with Lime of the weakeſt Kind, ſuch as that made from ſoft Chalk, will have the ſame laſting as Dung, that is, it will enrich the Land for three Years. Good Stone Lime well made and well laid in, will very well laſt Five Years. With Horſe Dung its Virtue will hardly hold out quite ſo long; but with Cow Dung it will afford two good Crops more. But then it muſt be allowed, that the firſt Crops from Horſe Dung and Lime will be richer.

Lime, with Aſhes made by burning the Land, laſts but three Years in its full Effect: but then the Land is not left ſo impoveriſhed, as it is where the Burnbaiting has been practiſed on it alone.

The Dreſſings of Lime and Mould, are the moſt durable of all: and with a little Refreſhment of the Land, at Times, will laſt ten or twelve Years.

This is what Experience confirms, and the Farmer ſhould regard it accordingly.

Additions to the Article of Lime, from a Correſpondent; containing an Account of making and uſing it in Staffordshire *and* Derbyshire.

There are ſuch great Improvements made by Lime of late Years, and ſuch prodigious Quantities now burnt, in compariſon of what was within the Memory of many now living, that it may deſervedly be called, A general Improvement; and perhaps, if all Things be duly conſider'd, it will be found the moſt uſeful artificial Improvement in the whole Kingdom; and conſequently deſerves to be conſider'd in a very particular Manner, from the Method of getting it in the Stone Pit, to the Manner of burning it into Lime, and ſo carried on through the various Ways it may be uſefully applied in, as well as the ſeveral great Improvements produced by

by it when properly applied, to almoſt all Sorts of Corn Land, and Graſs Grounds, both natural and artificial.

But before I enter into theſe Particulars, it may be proper to obſerve, that Lime-ſtone Ground, is generally of a ſweet and rich Nature, and the Waters which run from it, very much improve the Lands they flow over; whereas thoſe Waters which come from barren Heaths, and ſeveral other Sorts of hard Land, are frequently prejudicial, and do great Damage to the Grounds they flow over.

The Richneſs of the Dove Bank Lands in Staffordshire, which have been eſteem'd equal to any in England for feeding, is certainly owing to the Waters running from the Lime-ſtone Hills, and the Sheep Dung they carry along with them; ſo that they who have proper Opportunities of turning Lime-ſtone Water over their Grounds, may know how to apply it for their particular Benefit; and alſo to avoid ſuch Waters as are prejudicial. And the Waſh of plowed Fields and rich Meadows are alſo frequently very advantageous, where they can be properly applied, as well as the Waſh of Rivers paſſing near great Towns.

And indeed Lime-ſtone itſelf which has not been burnt, will alter Ground for the better, as is evident from ſeveral Places on the Moors, where Loads of Lime-ſtone having been ſhot down, and lain there ſome Time, it has quite alter'd the ſame from a coarſe ſour Graſs, to that of a kind ſweet Sort.

There are two Sorts of Lime-ſtone commonly to be met with, one a beddy Sort lying almoſt in Courſes, and in ſome Places almoſt as even as Bricks, which is generally got pretty eaſily, eſpecially if Beds of Earth lie mixed with it; of which a Man will then get a great Quantity in a Day, ten or a dozen Ton or more; and this Sort is commonly of a yellowiſh Caſt, and in general makes the whiteſt Lime; and a ſolid ſquare Yard is commonly computed a Ton.

The other Sort is uſually of a more rocky Nature, and much harder to be got; ſo that we are often forc'd to blaſt it with Gun Powder; and if the Rock be very firm, it is ſcarce to be thought what large Pieces of the Stone will ſometimes be blown into the Air, and how a little Powder in an Augur-hole, at about ten or twelve Inches deep, cover'd with Sand, will pierce the moſt ſolid Rock, ſhake it, and open the Joints ſo that it may be got by Wedges: but if the Rock be jointy, the Blaſts will generally have little Effect, as the Powder then finds a Paſſage through the Joints.

Stone of this Sort is in Reality the ſame as Peak Marble, and where it will bear poliſhing, is got and uſed for that Purpoſe, and very large Pieces are met with in ſome Places proper for it.

This Stone is commonly of a blueiſh Caſt, and ſpecifically heavier Foot for Foot than the other Sort, and conſequently muſt turn out more Lime when burnt, and is generally eſteemed ſtronger for Land than the other, though the former is whiter: for which Reaſon I uſed to ſend for the former for the laſt waſhing a Room. And here I cannot but obſerve, That I never knew or heard that any Workmen, though employ'd for Numbers of Years, and almoſt conſtantly both Day and Night, engaged in the Smell and Smoak of a Lime Kiln, were ever any way prejudiced in their Health by it, tho' it is Death to all Vermin about them; and we have frequently Inſtances of Perſons loſing the Uſe of their Limbs, or their Lives, by going too ſoon into green Houſes, or Rooms new ſhot with Lime, before the Mortar made of this Lime and Sand, has been very well aired, and long ſeaſoned.

In this laſt mention'd Stone are found that infinite Variety of ſeeming Shells and Bones, which are viſible in the Peak Marble; and, to give any tolerable Account of which, has ſo much perplexed the Philoſophers.

I have ſeveral, and have ſeen Numbers of ſeeming whole petrified Cockles, Oyſters, and Bones of Fiſh; and have one which is in Appearance the petrified round Back Bone of a Fiſh, with fine riſing ſharp Edges, at equal Diſtances, not half an Inch Diameter; the whole of about three Inches long, faſt at each End in the Piece of the Lime-ſtone it is in.

There are two Sorts of Sale Lime Kilns uſed in different Parts of Staffordshire and Derbyshire; one of which they fill, and cloſe, or ſhut up, burn it, and let it cool; and then draw it all out, the Days being appointed for the Farmers to fetch it. Theſe Kilns generally hold thirty or forty Quarters of Lime, being ſix or eight Waggon Loads; ſo that Mr. Ellis muſt be miſinformed about a Load being a Kiln of Lime near Derby.

And indeed every new lighting a Kiln occaſions ſuch Loſs and Expence, conſidering the Quantity of Lime burnt in one, that few like it; for which Reaſon thoſe called running Kilns, commonly kept in from the Time they are lighted, as long as they have Cuſtom, and often from April to October, are generally choſe for Sale Kilns; and alſo by thoſe who burn for their own private Uſe.

The publick running Sale Kilns are generally about ſeven Yards deep, and contrived either at the Side of a Hill, or by ſinking the Ground, ſo that the Workmen may have Room at the Bottom under the Cover of the Kiln to draw out the Lime, and alſo Conveniency to lay ſome by, and to ſet ſome Loads ready for Cuſtomers, and the Top of it to be readily come at, to bring the Stone and Coals to burn it with, and to have Room to break the Stone, and fill the Kiln.

The Bottom ſhould be laid with a good Stone dipping toward the Mouth it is drawn at; and at about two Foot high, there is a Stone runs croſs the Kiln, called a Horſe, for the Lime to fall down on each Side of it, and to prevent the Lime falling down altogether; which Stone ought to be ſuch as will bear the Fire, ſince if it break, the whole muſt ſometimes be drawn out again not well burnt: and the Stone facing the inner Part ſhould alſo be of the ſame Nature, eſpecially toward the Bottom. Sometimes indeed Lime-ſtones are uſed alſo for the Inſide near the Top, and will laſt a Year, and may be eaſily repaired the following Spring.

The Kiln, here, widens gradually from the Bottom to nine or ten Foot high, to about nine Foot wide, for about two thirds of the Height, and then is drawn in again gradually to about ſix Foot wide, which makes it burn better, ſave Coal, and is eaſier cloſed up at the Night till Morning; ſo that the Fire gets not up too ſoon and waſtes, when the Stone is commonly heaped up high like a Pyramid.

At firſt lighting it, towards the Bottom, they uſe Wood or Gorſe (Furze) then half Coal and half Stone, and encreaſe the Quantity of Stone gradually, till they ſet on twenty Scuttle full of Coals to ſixty of Stone, which is called a Bed, which Stone is about a Ton; and when the Kiln is warm and goes well, one Horſe Load of Sleek, or Coals, will burn two and an half, three, and ſometimes, in good Weather, more Loads of Lime; and a Kiln will draw ſeventy or eighty Sale Horſe Loads a Day, which are generally about three Buſhels, even by the Wood, to the Load, or two and an half full up-heap'd Meaſure: two Buſhels which I burnt, of full Meaſure, was fourteen Stone Weight, and few Sale Carriers will carry more. What is called a Buſhel in the South, is called a Strike in thoſe Counties.

The Coals, or Sleek, they burn Lime with, are uſually an ordinary Sort of Coal, ſubject to ſmell and ſmoak very much, and conſequently are little burnt in better Families; the Price of them is about Two-pence per Load, and the Expence of Carriage, according to the Diſtance from the Lime Kiln, generally about a Penny a Mile in Staffordshire.

Theſe running Kilns burn Lime much cheaper, and full as well as thoſe that are only once filled, burnt, and let out again; and have not ſo much Waſte in Proportion, and, I think, few ſeem to have any juſt Notion of Lime burning, which makes me ſay ſo much on this Subject.

A running Sale Kiln employs four Men; one to get the Stone, one to wheel it to the Kiln, and the other to draw the Lime, fill the Bags, and help to load Horſes, and ſet on Beds of Stone and Coals above, in Proportion to what is drawn below.

The Wheeler has but common Labourer's Wages, the Stone-getter, according to the Nature of the Stone, but the two Burners, who ſeldom leave the Kiln, expect, one Way or other, near double Labourer's Wages, or more, eſpecially as they ſhould be experienced; and are generally tied to it from April or May, till October, according to the Seaſon and Cuſtom. So that any Perſon may pretty near compute the general Expence of burning of Lime, great Part of which depends on the Nearneſs and Cheapneſs of Coals and Lime-ſtone.

The building my private Kiln coſt me about three Pounds, and it would draw fifty, or near ſixty Quarters per Week of up-heaped Meaſure; and with very little Repairing has laſted, occaſionally, above thirty Years; and I had the Stone got and bedded, and gave a Man and his Boy One Shilling and Six-pence for each ten Quarter they burnt and delivered, but generally let him have ſome farther Advantages.

The Curious will excuſe my mentioning an Obſervation, made by ſeveral Lime-burners; that all the Art they have, about May they cannot keep the Lime from falling to Powder, though they can, for a conſiderable Time, at all other Seaſons; and ſome of them think the Return of the Heat and Spring has an Influence upon the Stone, as well as upon Plants and Animals.

There is one thing relating to Lime, it may be proper to caution thoſe concerned with it, to be careful about; which is, that they be very cautious how they lay it in Buildings, or near Wood, or any thing combuſtible, ſince it is very ſubject, on Wet coming to it, or even ſometimes with the Moiſture of the Air or Earth, to fire any thing near it. And on very wet Days Lime has ſometimes fired the Sacks on the Horſes Back, and the Carriages it is taken in from the Kiln.

The common Price at the Sale Kilns, near Buxton in Derbyshire, and at Caldon Grange in Staffordshire, is about Five Shillings and Six-pence the Sale Load per Score, and Four-pence per Load to Farmers, who generally carry three up-heaped Buſhels, there called Strikes: and from thoſe two Places, I apprehend, there are full a thouſand Loads a Day carried round the Country, beſides what private Perſons burn for their own Uſe.

Some of the preſent Lime Burners, at the publick Sale Kilns, now make uſe of Waggons, like thoſe uſed to run on wooden Frames, at the Coal Pits in Shropshire, and at Newcastle; which, going on low wooden Wheels, and on a Frame of Wood, are eaſily loaded, and drawn from one Place to another; and, when placed over the Boat, forty Hundred of Coals are unloaded into the Boat in an Inſtant, by opening a Trap Door at the Bottom of the Waggon, and the Coals drop down. And the Lime Burners load Waggons like thoſe with Stone, broken to the proper Size at the Stone Pit, and then draw the Waggon over the Kiln, on a Frame, and then unload it into it by the Trap Door; which ſaves all the uſual filling of Wiſkets, and then throwing them into the Kiln one by one. And by this Method two Men almoſt do the Work of four, to the great weekly Advantage of the Owners.

There is one Thing I have frequently obſerved, that old Stone is neither ſo eaſily burnt, or makes ſuch kind Lime as that which is new got, and even lying a few Days when got, expoſed to the Air and Weather, is to its Diſadvantage in the burning it into Lime, as well as the out Part of the Lime-ſtone Rock, which has been long expoſed to the Wind and Weather. And the ſame has been commonly obſerved of ſeveral Sorts of Free-ſtone, that they are much ſofter and eaſier worked when new got, than when they have been expoſed to, and hardened by, the Air, Sun, and Weather.

There is ſome Art and Care neceſſary in breaking the Stone in proper Sizes for the Kiln, and the great Hammers are made with Faces ſuitable to that Purpoſe; for a large flat Stone will be burnt well, when a round lumpiſh one will not, though of much leſs Size. And the throwing in much ſmall Stone is ſubject to choak the Fire, nor is it choſe but when they lay ſome round the Edges, to prevent the Fire burning too furiouſly there.

Before

Before I enter into the general or particular Uſes of Lime, there are two or three Things which, from my own and other Peoples Experience, I would particularly recommend to the Reader.

The firſt of which is, to Lime the Ground (I ſpeak chiefly here of Graſs Ground) as ſoon in the Year as conveniently may be; for I am ſatisfied that Lime laid on Ground before MIDSUMMER, is much more beneficial to it, than what is laid on ſome Time after. And the later it is laid on in the Year, it muſt conſequently be proportionably the worſe for it; though the Lime Burners will tell you it is equally good then.

But as to laying it on ploughed Land, the Courſe of Tillage muſt be obſerved; and as to Compoſitions, or Mixtures of Lime and Dung, and Soil, &c. the Seaſon of the Year is not ſo much to be regarded.

But in all theſe Caſes I would adviſe, not to let it lie and mortar (as they call it) before it is uſed, which is a great Miſtake, and very prejudicial, though I have known ſome old Farmers practiſe it; but by all Means ſpread your Lime while it is in the Flour, when it is laid on Graſs Ground.

And I think it not adviſeable to lay Lime on where there is much Graſs on the Ground, which certainly muſt prevent its having ſo good an Effect on the Ground, as it will when the Ground is barer; nor will a Farmer be ſurprized to find, that his Cattle will not touch the new limed Ground, until ſome Rain has fallen to waſh the Lime a little in. After which they will eat of it, and prefer the Graſs of the limed Ground to any Quantity of Graſs of the unlimed Part of the ſame Field; but in a long dry Time it would not be prudent to Lime a Paſture all at once, for the Reaſon above.

The moſt learned and judicious Perſons will not pretend to aſſign Cauſes.—"I confeſs (ſays "an ingenious Gentleman) that I am ignorant "of the Cauſe of this great Power (of Lime) "whoſe Effects are aſtoniſhing, as much as I "am of Elaſticity or Attraction; though per-"haps it is nothing but a Modification of thoſe "two conjoined, acting on, and exciting the "Fluid of Fire, which pervades, and is con-"tained in every thing." But however unknown the Cauſe may be, or whatever Diſputes there may have been amongſt the Learned, to what Sort of Land it is properly applicable, and to which not; yet all agree, That,

Lime is an excellent Manure, rightly and diſcreetly applied, though they differ as to its operative Effects, and the Manner of applying it.

But what I am at preſent concern'd in, is not now to explain the Nature of Lime, or its ſurprizing Effects, and the Manner of its working; but only to ſhew how beſt to preſerve that Power, and apply it beſt to the Ends deſigned, that is, the Farmer's Benefit; and not let its Virtue be loſt, or waſted to no Purpoſe; which will explain, and in ſome Meaſure, juſtify the Directions above given.

Now it ſeems very evident, that all the Benefit of Lime muſt ariſe from ſomething in the Nature of the Stone itſelf, or elſe from the Heat communicated to it in the Lime-Kiln, or from both, and the Effects they produce in the Earth. And therefore the ſooner it is applied the greater Effect it muſt have; for it is very evident, that it loſes of its Heat and Virtue by lying expoſed to the Air, and that if wet gets to it, it muſt cool the Heat of it, and will make it (as they call it) clotter in Lumps, which muſt not only weaken the Force of the Fire within it, but alſo prevent the fine Particles of it operating, as they would other wiſe do; and will prevent, or at leaſt leſſen, that Fermentation which is generally thought to produce that uſeful Vegetation occaſioned by Lime.

And certainly if Lime is laid on the Ground early, and when it is bare, whilſt fair warm Weather may reaſonably be expected, and ſpread whilſt it is the Flour, it will then enter the Pores of the Earth, and produce the deſired Effect there much better than when Rains fall, or cold froſty Nights leſſen its Goodneſs, or when much Graſs, or the Dews commonly on it cool the Lime, or abſorb the fine Particles of it, or at leaſt prevent its eaſy entering into the Ground.

It was before mention'd, that the moſt judicious in their niceſt Enquiries, do not pretend to aſſign Cauſes; that being in Truth out of the Reach of human Underſtanding, however vain and preſumptuous ſeveral are in their Pretences to explain every Thing.

Dr. WALLIS, Mr. DERHAM, and Mr. HALLEY, freely confeſs it in their moſt curious Treatiſes on Philoſophical Subjects; and Mr. HALLEY in his Treatiſe, Of the Effects of Gravity, mentions ſeveral pretended Explanations of it, and ſays, "This is ſo far from explaining the Mo-"dus, that it is little more than to tell us in "other Terms, that heavy Bodies deſcend be-"cauſe they deſcend." And after anſwering their Arguments, then adds, "Though the effi-"cient Cauſe of Gravity be ſo obſcure, yet the "final Cauſe is clear enough; for it is by this "ſingle Principle, that the Earth and all the "celeſtial Bodies are kept from Diſſolution, "which infinite Wiſdom ordain'd for their Pre-"ſervation."*

* *Philoſ. Tranſact. vol.* 1. *p.* 471.

The learned Dr. FREIND, after many Conſiderations on this Subject, is at laſt for reſolving this, as well as other Things of this Kind, into the Will of God; and adds, "It appears there-"fore that the true Method in which Philoſo-"phers muſt proceed in their Inveſtigation of "real Science, is

"Firſt, They muſt ſearch out the Natures "and Forces of Bodies by a Multitude of Ex-"periments; then neglecting to enquire into the "Cauſes from whence they proceed, they ſhould "purſue and explain the Phœnomena that reſult "from the innate Virtue of every one."

To apply what is before mention'd to the not being able to aſſign the Cauſes of Things, to this our preſent Subject of Lime; it appears hence very plain, that it would be of no Uſe to pretend to explain the real Nature of Lime, or the Manner how it operates on Bodies in reſpect to altering their Natures, or improving their Vegetation.

That it does ſo in numerous Inſtances is evident beyond Diſpute; and from the many Ex-

periments already made, we may naturally conclude, that the ſame Cauſes will generally produce the ſame Effects, and conſequently we may juſtly apply it in the ſame Manner, and thereby reaſonably hope to obtain the ſame profitable End.

And thus by duly conſidering the Strength of our Lime, the Nature of the ſeveral Soils, the different Graſs Grounds, the various Plow Grounds, the very different artificial Graſſes, Plants and Herbs, to which we may, or intend to apply Lime; we may learn to proportion it to them reſpectively in ſuch Manner, and in thoſe ſuitable Seaſons, as may beſt tend to their ſeveral Improvements to our great Advantage: and alſo thereby learn to avoid every Thing prejudicial or fatal, which the over-liming Lands, or liming them improperly, might occaſion.

To give an Inſtance from Mr. Ellis, as to the Strength of Lime. He concludes that Lime agrees beſt of all with the cold wet Clays, becauſe his Neighbour with the limy Rubbiſh of his Kiln, dreſſes his high Clay Grounds that annually returns him vaſt Crops.†

† *Vol* 8. *P* 332—5.

Now if I underſtand Mr. Ellis right, what he calls limy Rubbiſh at the Sale Kilns, is called Lime Aſſe, and is of ſo little value, that Mountains of it are thrown by, it not being thought worth the Carriage to any Diſtance, as being a Mixture of ſmall Lime, Refuſe of the Coals, and accidental Rubbiſh; and a Cart Load of it is not thought of equal Value for the Ground as one Horſe Load of good Lime; and accordingly it is laid as thick on the Ground as common Dung.

So that this limy Rubbiſh partaking much of the Nature of Aſhes, can be no good Argument for Lime being beſt for cold wet Clays, which it certainly is not; though this Rubbiſh might improve his Neighbours wet Ground, and ſuch will be of Service to Land of this Sort when laid on in great Quantities; and if Chalk was burnt by Mr. Ellis's Neighbour, it will be ſtronger againſt Mr. Ellis, as that is not equal to Lime-ſtone in Strength and Goodneſs.

Again, Lime is found very beneficial to dry Lime-ſtone ground, where there is a tolerable Depth of Earth, but ſhould you lay a great Quantity of it where the Soil is very ſhallow, you would not only loſe the Expence of the Lime, but prejudice the Ground that it is laid on.

No experienced Farmer would expect any uſeful Produce from Lime laid on an entire Clay, or on an Heap of bare dry Sand, without what we call Earth or Loam, or ſome mix'd Soil over it: and there are ſome Lands very near ſuch bare Clay and Sand, to be met with in ſeveral Places, and to lay Lime directly on either of them, would certainly be both Labour and Expence in vain.

Too large a Quantity of Lime alſo will be hurtful, and this is the Caſe in all Manures whatſoever, both natural and artificial. For if you lay on too great a Quantity of any of them, inſtead of improving your Land, you will certainly ſpoil the preſent Produce of it, and ſome times for Years; till different Huſbandry, or the repeated Operation of the Sun, Air, and Weather, have brought the Land again to a proper Temperament, fit for the Growth of the Vegetables expected from it.

Inſtances of great Faults of this Kind in Dungs are not very common, and where they are committed, the Land will generally ſoon recover of itſelf.

But there are other Inſtances in Marle, and particularly of Salt Water, frequently to be met with; where, if too much of the former be laid on, or too much of the latter lie long on, or come too frequently over the Ground, ſuch Land will not be of any tolerable Goodneſs for many Years; and in ſome of theſe Inſtances never, until the Cauſe be removed, or a Remedy applied.

There have been ſeveral Inſtances of over-marling Land in Cheshire, by which the Ground has been quite ſpoiled for many Years; which yet after the Sun, Air, &c. have reduced it to a proper Temperament, has been very fruitful for many Years after.

And as to ſuch-like Effects of Salt, though that is certainly a wonderful advantageous Improvement, when properly applied; yet there are numerous Inſtances where the Salt Water accidentally lying too long on, has ſpoiled the Ground for a Year or two, which nevertheleſs were very fruitful for many Years after.

This was the Caſe of ſeveral Meadows of a near Relation of mine after the great Storm, as well as of ſeveral others.

But what will make this Matter evident beyond all manner of Diſpute is, the Caſe of the Marſhes and Lands near the Sea, which if conſtantly overflow'd every Time, produce very little of any Kind of Value; and the Lands adjoining to the Sea, if too often overflowed (by the Banks being let down) by high Tides. The prejudicial Effects are very viſible, for a Stranger may ſee by the Sort of Graſs how far the Sea Water uſually or accidentally comes too oft.

But when theſe Lands are well banked againſt the Tides, thoſe Meadows ſoon come to be good, and thoſe very Sea Marſhes gradually improve without any manner of Additions, or Huſbandry, to very good Paſture Grounds.

The ſame Effects muſt be naturally expected, and are accordingly found where Land is over limed; which recovers not, as obſerved by theſe Gentlemen, till tendered and altered by the Application of Things of a different Nature, or it be mellowed by Time.

And is not this the Caſe of every one of the different Improvements above mentioned in general; and alſo in a Thouſand other Inſtances in particular; in which if too much of one Sort of Manure or Improvement for one Sort of Tree or Vegetable be applied, it hinders its Growth, and perhaps proves fatal: when this very ſame Quantity of Manure would encreaſe the Growth and Goodneſs of other particular Trees and Vegetables, after a very ſurprizing and wonderful Manner.

On all Ground where any one would offer to lay Lime, there is a Coat of Earth or Loam Soil, though ſometimes very thin, not even an Inch and an half, and in others to a very great Depth;

Depth; in both which Lime will be uſeful, if applied ſeaſonably and in proper Quantities, according to the Depth, the Tenderneſs, or ſtiff Nature of the Soil; and it is the proper proportioning the one to the other, in which the Art of making Lime, and indeed of all other Manures, beneficial conſiſts.

In ſeveral Parts of the Moor Lands in STAFFORDSHIRE, where the Ground is generally moiſt, and the Soil of a tender Sort, and often very ſhallow (much of it having been pared off for firing) yet even here, Lime ſpread on the Surface, without any further Care, ſweetens the Ground (and what they call there breaks it) generally in two or three Years, and produces a ſweet Kind of Graſs. This will continue good as other Lands, unleſs impoveriſhed by too much plowing, or carrying off the Produce, by which any Land may be prejudiced; but here, if you plow into the Clay, you ſpoil the Land.

I have limed Land of this Sort from four to nine Inches deep of Soil, laying on forty Buſhels, up-heaped, on an Acre; ſome of which brake and paſtured pretty well in two or three Years, whilſt other Parts of it were ſix or ſeven Years before it anſwered well; after which I plowed it up, and had very good Turneps, where I ſowed ſome, and good Crops of Oats on other Parts. And it will now paſture very well, and mow too after, provided it be not plowed above two or three Years, and it would be well then to give it a little Muck.

In moiſt Lands of this Sort the Lime is ſubject to ſink deep where the Soil is ſo; for which Reaſon it is oft convenient to plow it before it be gone too far, and the Benefit of it, in ſome Meaſure, loſt out of the Reach of the Corn and Graſs growing on it.

In the PEAK of DERBYSHIRE a great Quantity of Lime-ſtone Ground, with a coarſe Turf, has been improved with only liming it, and then letting it lie for Paſture Ground without any further Trouble or Concern about it, and it anſwers very well. Some Perſons have got good Eſtates by taking long Leaſes of Parcels of Commons, when divided, and then liming and ſetting them out again.

And here it may not be unuſeful to mention what happened to one of my Tenants, who was a very good Houſewife, yet found her Cheeſe bad, though made as uſual, the Year after the Ground was limed, which had ſo enriched the Milk, that it was neceſſary to break the Curd a great deal ſmaller than ſhe uſually had done, to make her Cheeſe then good; which ſhe thenceforward obſerved, and made exceeding good Cheeſe.

Theſe Inſtances confirm what was before mentioned, that Lime ſweetens Land, not ſours it, as Mr. SWITZER mentions; nor is it to be taken as one of its good Qualities, to abſorb the Wet, as Mr. ELLIS is pleaſed to imagine.

But the great Art in relation to Lime, and indeed to all other Improvements, is, how to proportion the Sorts and Quantity of the Manure to the different Soils, and to the Nature of the Things deſired to be produced; which, as to Lime, may be pretty eaſily collected in common Caſes, from what is before mentioned; and in any uncommon Caſe, may be readily brought to a Certainty, by a few Trials on ſmall Quantities of Land; and in moſt Caſes, eſpecially in good Land, with ſhallow Soil, it is better to repeat, than to lay great Quantities of Lime on at one Time.

O.

CHAP. XXXVII.

Of Soot.

WE come now to the Conſideration of another of the artificial Manures, which is alſo the Product of Fire; nor are theſe two all that the Huſbandman owes to the ſame Principle: Aſhes of various Kinds come in a natural Way, from the Effect of Fire upon our common Fuel, at the ſame Time that the Soot is formed: and they likewiſe are very beneficial to the Farmer.

Soot is of two general Kinds, the one, that which ariſes from Wood, the other that of Coal. Theſe differ very much in many Reſpects, but they are nearly the ſame in their Effects and Value to the Farmer. The Wood Soot is ſolid and ſhining, the Coal Soot looſer, and of a deader Colour. The Wood Soot ſells in LONDON at a great Price, in compariſon of the other, for the Uſe of Chymiſts and Apothecaries, becauſe it is ſcarcer, the Fuel of LONDON being, in general, Coal: but in the Country, where this is as common and cheap as the other, the Farmers rather prefer Coal Soot before it.

Thoſe who have written on Huſbandry, differ much in the Kind to which they give the Preference. MORTIMER ſays Sea-coal Soot is by much the beſt, and WORLIDGE tells us, that Soot is a good Manure, eſpecially ſuch as is made of Wood: theſe are both very honeſt and good Writers; but Experience is to be prefer'd to either. The Truth is, that neither Kind deſerves a general Preference, but that Wood Soot is better for ſome Soils, and Coal Soot for others. Indeed the latter is beſt on the greateſt Number of Soils, and therefore the Farmer is right in valuing it the more. However, this Difference is not ſo great, that any Danger can ariſe from a Miſtake about it, for ſuch Land as will do well with one Kind of Soot, will alſo with another: all that the beſt Choice can do, gives only a little Advantage.

As there are Soils which refuſe the Aſſiſtance of ſome of the moſt enriching Manures; there are others of equal Efficacy, which perfectly well agree with them. This is exactly the Caſe in the preſent Inſtance. Clayey Soils, as we have ſeen already, will not bear Lime; but Soot is the peculiar and appropriated Manure for theſe; and it will do for them, all that Lime does for the others. But in this the Soot has the Advantage of the Lime, that there is no Soil whatſoever but it ſuits.

As to the ſuiting the particular Kinds of Soot to the different Soils, the Rule is this. For all clayey, chalky, and moſſy Lands, the Coal Soot is beſt. And this is the Reaſon why the Coal Soot is moſt in Repute in LONDON for this Traffick, becauſe the HERTFORDSHIRE Farmers,

mers, who buy it almoſt entirely, have, for the moſt Part, clayey or chalky Soils to cultivate.

For gravelly, ſandy, and loamy Soils, the Wood Soot is preferable to that of Coal: and in its Nature indeed this Kind is better and richer than the other, becauſe, being made from a vegetable Subſtance, it is richer and warmer than that other which comes from a Mineral Origin; but the great Reaſon of the Difference which ſuits one Kind to one Soil, and another to another, is the Conſiſtence. The Wood Soot is in firmer and harder Lumps; the Coal Soot is crumbly; now in a clayey or a moſſy Soil, the Lumps of the Wood Soot would lie a long Time unbroken, whereas the Coal Soot breaks and mixes immediately. Experience ſhews alſo, that the Wood Soot will lie in large Pieces a long Time in a chalky Land; whereas the gravelly Sands, and ſandy Loams, cut and break it to Pieces in two or three Plowings, and ſpread and mix it thoroughly.

Perhaps it will be found, upon farther Experience, that the Benefit of Wood Soot is more laſting than that of Coal: but what the Farmer expects from Soot is, an immediate Effect upon the Corn. And in this he is not diſappointed, even on his coldeſt clayey Lands; for the Effect is like Magick. If the Soot be ſprinkled early over the Land, the firſt Shoot of the Corn will preſently be enough to preſerve the Root, and ſtand all Injuries; and the Virtue will continue with it to the full Ripening. A Field that has been dreſs'd with Soot may be diſtinguiſhed from one that has not, only by the Appearance of the Crop, at any Time. There is a Strength and Freſhneſs the Soot gives, that nothing elſe can.

Soot goes a great Way upon any Kind of Land. In general, a Buſhel of it, if it be tolerably good, is equal to a Load of Dung. Twenty Buſhels of Soot is a very fair Allowance for an Acre.

Sheeps Dung, as has been ſaid already, is, of all Manures, the very beſt for a dry Chalk; but the next in Value to that is Soot. For the ſandy Soils Lime and Soot are the two great Improvements; and the Advantage of Soot on Gravels would be much better known than it is, if it were not that the Practice of folding took its Place; than which indeed nothing is better.

The beſt Seaſon for laying on of Soot is toward the End of February, and as the Quantity that is neceſſary is ſo ſmall, in Proportion to that of other Manures, ſo much the more Care muſt be taken to ſpread it evenly and regularly: the Spring Rains perfectly waſh it in, when thus laid on; and the Effect is immediately ſeen.

The Benefit of Soot is not confin'd to Corn Lands; for it is of equal Uſe on Paſtures; and particularly on thoſe of a clayey Soil. When the Coldneſs and Hardneſs of the Ground has ſcarce ſuffer'd a tolerable Swarth to appear of many Years, a ſingle Dreſſing of Soot, ſprinkled on before the Spring Rains, has been known to produce inſtantly, as it were, a thick Covering of a fine ſprightly Green; with the Leaves full juicy and upright, and all the Signs of Health and Strength; and this has continu'd a long Time, though on Corn Land the Fruitfulneſs from the ſame Manure is ſhort.

Coal Soot is greatly to be prefer'd to Wood Soot for Paſture Grounds; for as there is there nothing to break the Lumps of the latter, they might lie a great while, and give up half their Virtue to the Air, inſtead of enriching the Land. The Coal Soot, on the other hand, waſhes all in immediately. After half a dozen Showers, if the Soot were pure and fine, it is not to be ſeen that any thing has been on the Ground. Aſhes are often mixed with Soot, by thoſe who ſell it for the Sake of greater Profit, but here the Cheat is at once diſcovered.

I would adviſe the ſprinkling a larger Quantity of Soot on Paſture, than the Allowance for Corn Lands: about thirty Buſhels to the Acre: and this is worth while, as the Effect is ſo much more laſting.

The Writers on Huſbandry direct forty Buſhels to an Acre of Corn Land; and though the preſent univerſal Practice allows but about twenty, perhaps the Farmer would find he got more, in the End, by this double Allowance, even to his plowed Fields.

CHAP. XXXVIII.

Of Aſhes.

ASHES of every Kind whatſoever, are of great Uſe to the Farmer, but in theſe there is a great deal more Difference ariſing from the Materials which yield them, than in Soot.

Aſhes as they come under the Conſideration of the Huſbandman, may be reduced to three general Kinds. 1. The Aſhes of his common Fires. 2. The Aſhes made by burning Stubble, Fern, Furzes, and other uſeleſs Produ[illegible] Land; and, 3. The Aſhes of the Land itſelf produced by what we call Burnbaiting; which laſt ſhall be treated of after the others as a diſtinct Article, and in a different Chapter.

The firſt of theſe Heads may naturally enough be conſider'd alſo in a double Light, for there is a great Difference ariſing from the Fuel; the Aſhes of Sea-coal being different from the Aſhes of Wood; and thoſe of Peat from both.

In general when the Farmer's Fuel is Wood or Peat, the Aſhes of his Hearth differ very little from thoſe of burning Fern or Stubble; but when he burns Pit or Sea-coal, they are quite of a different Nature.

I heard in Lancashire a very great Account of the Aſhes of what they call Cannel-coal; but upon examining ſtrictly into that Matter, I think them inferior to our common Sea-coal Aſhes: for they have no more Richneſs, and they want that Harſhneſs or Sharpneſs which the others have. So that they enrich no more, and they do not divide the Land ſo much as the common Coal-aſhes.

The Aſhes of Scotch-coal, which are alſo white and ſoft, are of a middle Nature between the Lancashire Cannel-aſhes, and thoſe of the London Sea-coal. They are better than the former, and not ſo good as the latter: and this for the ſame Reaſon, as the others are worſe, they want Harſhneſs to cut a tough Soil; and

this is one great Advantage arising from the Use of all the firmer Kinds of Manures.

Wood-ashes enrich a Soil more than Coal; the Coal-ashes divide a Soil more than they, and they enrich it also at the same Time, tho' in a less Degree: Coal-ashes are therefore best for a tough clayey heavy Soil, and Wood-ashes for a light, poor and barren; or a too wet Land. In general cold and damp Lands, are they which receive most Advantage from Ashes of whatever Kind.

Some Farmers think themselves very frugal in buying up the Wood-ashes, after they have been used in the bucking of Linnen; but they deceive themselves in this, for those Ashes have altogether lost their Salt, and are little more than so much barren Dust. I have seen great Disappointment from this Frugality.

Wood-ashes when they are fresh and full of their Salt, should be used alone. Coal-ashes having less Richness, are best mix'd with Dung: Horse Dung is fittest for this Service; or else the Compost of all Kinds of Dung together, which has been before describ'd; and this Way they make an excellent Manure. The Sharpness of the Ashes opening the Land in a surprizing Manner, and letting in the Virtue of the Dung.

Any Soil of whatsoever Kind that is too damp, will have Advantage from a good dressing of Ashes: and where the Dampness is the principal Fault, Coal-ashes are found to succeed better than those of Wood.

Soap Boilers Ashes after they have done with them have also great Virtue.

It is for this Reason of their correcting damp Grounds, that Ashes, and especially the Kind last mention'd, are so famous in Lancashire, and other Places, for the Improvement of their mossy Lands, and destroying Rushes.

As to the Quantity of Ashes to be us'd as a Dressing, four Load of Wood-ashes, and six of Coal-ashes, are the general Allowance for an Acre, but I think the Quantity may be increased with Advantage; and especially that of the Coal-ashes, which in Countries where Coal is the Fuel, are cheap enough, costing nothing but Carriage.

I have observ'd that the Ashes which have been us'd in bucking have no Virtue. We see by this that Wood-ashes may be robbed of all their Efficacy by Water; and for this Reason they must be laid up for use in some dry Place, and no Wet of any Kind suffer'd to come near them: otherwise the Farmer may chance to lay Dust upon his Land when he thinks he is giving it a rich Dressing.

Coal-ashes having a Salt also, though not so much as Wood-ashes, must be kept dry in order to preserve their Virtue; for if they lie expos'd to the Rains, they will be reduced to mere useless Matter: but it is found by Experience, that if these be moisten'd by emptying the Pots upon them from Time to Time; as also by throwing upon them waste Soap Suds, in which Cloths have been wash'd, or other such Liquors as have a Salt in them, they are enrich'd, and will go farther than alone.

The Ashes made by burning Weeds, Bean-stalks, Stubble, and other Vegetable Matters, are very little different from the common Ashes of the Hearth, where Wood is burnt, but they are somewhat lighter, and easily part with their Salt by the Rain. When they are burnt upon the Ground, they are also well scattered, and sprinkled equally, which does not always happen with such as are carried on in Loads.

To this Head are to be added Peat-ashes, which are of a particular Kind in this Respect, that they are lighter and softer than all others: but in general they are of the same Virtue with the Ashes of Vegetables; more like those of Stubble, and other light Kinds, however than Wood-ashes. All these give great Fertility both to Corn and Meadow Land; and the last nearer than any other, approach to that Kind which is made by burning the Surface of the Land, to be spoken of presently. But there is still this great Difference, that in the burning the Land the Soil is prepared to receive them.

The best Use of Wood-ashes is the strewing them by hand over Wheat Lands, in the very beginning of the Spring. This Purpose they answer best if they have been kept under Cover, and wetted gently with the emptying the Chamber Pots on them from Time to Time. The proper Quantity is about fifty Bushels to an Acre; and as they came cheap enough where Wood is the Fuel, this is no great Matter.

The Farmers in Hertfordshire and Buckinghamshire, have found by repeated Experience, that these Ashes answer the Purpose of their Soot Dressings perfectly well; they value the Discovery for its saving the Price of Soot: but the Farmers will value it on a double Account, where Soot is not to be had in Quantities, as is the Complaint in most Places in England. The Encrease this top Dressing of Ashes causes to the Crop, is greater than they could conceive who have not seen it.

The Use of Wood-ashes thus prepared, is not confined to Corn Lands, they are excellent also on Pasture Ground; but on this there must be a larger Allowance: fourscore Bushels is about the right Quantity to an Acre. And in this use they not only cause an early and plentiful Shoot of the Grass, but they destroy those Insects which are apt to harbour about the Roots to the great Injury of the Land.

Coal-ashes preserved and wetted in the same Manner, answer excellently on Pasture Grounds, and fifty Bushels of these will go as far as eighty of Wood. What I have seen from Experience is, that on Pasture Grounds the Wood-ashes take a more immediate Effect, but that of the Coal-ashes is more lasting. The first Year's Grass will be more plentiful from the Wood-ashes, but the Effect is less afterwards, whereas the Coal-ashes continue their Efficacy four or five Years very well.

Coal-ashes are also excellent for Clover, Saintfoine, and the other Grasses of that Kind. The Way of using them is soon after the Depth of Winter, to sprinkle them at the Rate of fifty Bushel to the Acre, and the Rains washing them in they do excellent Service.

It is a Custom in some Places also to spread Coal-ashes on the young Wheat, but Wood-ashes are best of all for this Purpose.

Where Peat-aſhes are to be had, they exceed every other Kind for the Clover and Saintfoine. But being light there requires a large Quantity of them.

Beſide theſe ſingle Uſes of Aſhes, they do excellently well in many Compoſts. Wood-aſhes are a very fine Mixture with Cow Dung: they alſo enrich the Heaps of Soil that are made from all Sorts of Refuſe and Dung thrown together. And Coal-aſhes are an excellent Addition to the Earth that is mix'd with Hens Dung, nothing ſo readily breaking the ſtringy Toughneſs of that rich, but untractable Manure.

Coal-aſhes agree excellently with a clayey Soil, and Wood-aſhes with the loamy and gravelly: but either may be us'd in the Place of the other without Damage in any Caſe; the only Difference will be, that there will not be quite ſo much Advantage where they are laid on inconſiderately; as where they are ſuited to the Soil.

CHAP. XXXIX.

Of Burnbaiting.

TO the Head of Improvements of Land by Aſhes, may be properly enough refer'd the great and valuable Practice of burning the Baite or Turf, called in ſome Places Burnbaiting, and in others Denſhring of Land, from the Name of the County in which it was firſt a general Practice. Nevertheleſs it demands to be treated ſeparately, becauſe of the particular Method of doing it, and the great Advantage the Land receives from that Method of Management, and Application of the Aſhes.

Burnbaiting is perform'd by cutting off the Turf of the Ground, piling it up in Heaps to dry, and afterwards burning it to Aſhes; which Aſhes are ſpread over the naked Surface, and plow'd in. This is the Practice in general Terms. It had its Name Burnbaiting from Baite, an old English Word for Turf. For the Sake of the practical Huſbandman I ſhall lay down ſome Inſtructions relating to the Manner of performing it, before I enter on its Advantages, which I hope to teach him not only to obtain but to preſerve. This laſt Article is a Secret yet unknown to all our Farmers.

In the firſt Place the cutting off the Turf, as it is univerſally done at this Time, will admit of great Improvement. The preſent Method is this.

A ſtout Labourer puſhes a Breaſt Plough before him by the Strength and Weight of his Body and Arms, at a ſmall Depth under the Turf. This is a plain and poorly contriv'd Inſtrument, conſiſting of a Kind of Share, with an Edge for cutting the Turf, a Handle, and a croſs Piece at Top. They pare off the Turf with this about an Inch thick, more or leſs, according to the Quantity of Roots, or other Vegetable Matter there is in it; for the more there is of this, the thicker the Turf is to be taken off. It is thus cut into Pieces of a Foot and half long, and nine or ten Inches broad, and turn'd that it may dry.

It is evident that a Plow with a proper Share, drawn by a Horſe, would perform this Buſineſs in a much quicker and more advantageous Manner. There is a very convenient Inſtrument for the Purpoſe, deſcrib'd in a late Treatiſe on this Subject, which though I have not ſeen us'd, yet is ſo plainly uſeful and fit for the Purpoſe, that I ſhall propoſe it to the Farmer's Conſideration.

A hollow Plowſhare riſing with a ſharp Edge in the middle, from the Point to the Top, and having a Fin both Ways, beginning at the Point and running back to the Share, muſt be fix'd to a light and ſtrong Piece of Aſh ſharpen'd forward, but left thick and ſtrong behind.

The Share ſhould be two Foot broad from Point to Point of the Fins behind; a Foot long; and a Foot high. To the End of the Aſh Pole muſt be faſten'd a ſtrong Piece of Wood nearly perpendicular, but hanging a little backward: this muſt be two Foot high, and on the Top muſt be a croſs Piece for faſtening the Harneſs of the Cattle. This is eaſily underſtood, and any Country Workman can execute it.

The Handles of the Plow, and the Earth Boards to turn the Turf, are to be fix'd alſo into this ſquare Head. The Inſtrument is then compleat, and every Plow Boy will be able to manage it properly with a little Inſtruction.

He muſt begin at the Edge of a Field, and as he goes on, one Turf will be turn'd toward the Fence, the other inward. When he returns he muſt direct the Plow juſt along the Edge of the laſt mention'd Turf, for it covers a Part of the Ground that is not cut up. This will be cut up at the Return, and turn'd over with the other.

In this Manner the whole Field is to be pared; and the Turf will then lie in long Pieces reaching from one Side to the other. There requires after this the cutting it into Lengths: but this muſt not be called an additional Trouble, the former having been ſo very trifling in Compariſon of what is commonly requiſite to that Purpoſe. The Gentleman who invented the Plow, has alſo contriv'd a very plain and ſimple Inſtrument for this Purpoſe.

A Roller is to be made of the Trunk of a ſound Tree, firm, large, and heavy. It is to be hoop'd round at every two Foot, and from the middle of each Hoop is to riſe all round a Blade ſix Inches deep, ſtout at the Bottom to ſupport it againſt bending, and ſharp at the Edge. The Roller thus arm'd, is to be drawn over the whole Field Croſs-ways; and its Weight preſſing the Edges all the Way down, the Turf will be cut through and through at every two Foot. By this Means the whole Surface will be cut into Turfs of two Foot long, and one broad, which is a very proper Size.

Having thus given a convenient and expeditious Method of cutting up the Turf, we are to proceed to the drying, piling, and burning of it: for howſoever plain and ſimple this Operation may ſeem according to the few Words in which the Writers on theſe Things have deſcribed it; a great Part of the Benefit the Farmer

mer is to reap from it, depends on a very critical Regard to every Part of the Proceſs.

If the Soil be light, and the Weather hot and fair, the Turf will dry with once raiſing up and turning: but if either its own Dampneſs, or the Wetneſs of the Seaſon prevent this, it muſt be piled together as hollow as may be, in little Heaps; where Paſſage being left between the Turfs for the Wind, they will quickly be dry'd. Sometimes juſt ſetting them on Edge againſt one another will anſwer the Purpoſe.

When they are dry enough for firing, the Turf will in ſome Places burn ſingly and of itſelf; in others it muſt be aſſiſted with more inflammable Materials. The Farmer may know whether he be to fire it alone, or to give it this Addition by obſerving its Nature as 'tis turn'd up.

When the Soil is very poor, the Turf thin, and few Roots among it, it will not do alone. On the other hand where the Soil has been better, the Turf cut deeper, and there is a great deal of Roots in it, and of Stalks, and dry Leaves upon it, 'twill burn alone, and he is to give it no Addition.

In the other Caſe he is to ſtrew a little dry Heath or dry Furzes under every Heap, and if it be very poor, and he make his Heaps large, he muſt mix ſome of the ſame dry and inflammable Materials among the ſeveral Turfs of every Heap.

'Tis beſt, however, to make the Heaps ſmall, whatever be the Soil, or the Condition of the Turf; for thus they always burn beſt, and being more numerous, they improve more of the Surface of the Ground in the Act of burning: for 'tis not only by Means of the Aſhes that barren Grounds thus treated are improv'd, the very heating of them by theſe ſeveral Fires tends to divide their Particles, and encreaſe the Fertility they are gaining.

Some make a great Art of raiſing theſe little Heaps of Turf for Burnbaiting, compoſing them of ten or a dozen Turfs each, which they twiſt curiouſly together, leaving a Hollow within; and Holes between in ſeveral Places, as if they ty'd them into Knots like Ribbands, or imitated the Flouriſhes of a Writing Maſter's Pen. They then draw in Pieces of Furze between the Holes, and fill the hollow Part with it. To this there is no Objection, but that it is a greal deal of needleſs Trouble.

A good Wheel-barrow Load of the Turf is ſufficient for each Heap, and if they are of the poor Kind, a little dry Furze ſhould be laid upon the Ground under and between them, this is all that is needful. The Labourer then is to ſet them up end-ways, and edge-ways, as looſe as he can; and when all the Heaps are thus rais'd, and have ſtood a Day or two for a farther drying, the Furze is to be ſet on Fire; and they will catch from it, and burn away ſufficiently for the Farmers Purpoſe.

Let us now examine the Matter of burning them: for on the doing this properly, as much at leaſt depends as on any Part of the Work. Many a Huſbandman after all his Toil and Expence, has loſt half, nay, two thirds of his Advantage from the ſingle Circumſtance of not regarding, or not knowing the proper Degree of burning.

Now in order to explain this it is to be obſerv'd, that Fire carries off all the efficacious Parts of moſt Subſtances; but this it does gradually; and the Progreſs may be ſeen. The Farmer wants to reduce this Turf to Aſhes; but as he wants theſe Aſhes to enrich his Land, he ſhould get them as full of Virtue as he can.

If a Plant of any Kind be put into the Fire, it burns away to Aſhes, but theſe Aſhes at different Times of the burning differ very much in Appearance, and alſo in their Qualities. When the Plant firſt falls into Aſhes, thoſe Aſhes are of a blackiſh grey; and as they continue in the Fire they become paler and paler, till they are at length perfectly white. While they are of a dark grey, they have a great deal of Taſte, but when they are burnt white, they are only a little brackiſh.

The Philoſophers and Chemiſts tell us, that this Colour is owing to the Oil of the Plant, as alſo the Taſte; and that this Oil, burning away, leaves the Aſhes pale, and of half their Virtue. Very likely this Account is true. The Colour and the Taſte muſt be owing to ſomething, and whatever that is, it burns away afterwards. Whether it be the Oil or not matters nothing.

We don't know what Principle it is in Aſhes that gives Fertility to the Ground; but whatever it be, 'tis beſt to preſerve it as entire as poſſible. Now let us apply this Reaſoning to the Huſbandman's Burnbaiting, and we ſhall ſoon ſee the Reſult of it, and what Practice it directs.

Let the Farmer mark the Courſe of the Operation in the burning of one of theſe Heaps of Turf. He will find, provided the Fire go on well, that at firſt all the Heap looks blackiſh and duſky; then the Turfs which compoſe it, after a Time, begin to crack and crumble to Pieces: a little while after this he will ſee them mouldер into an Heap of rediſh or yellowiſh Aſhes, with ſeveral Lumps among them; and a while after this a great Part of the Lumps will moulder away, and the Aſhes, in moſt Parts, become of a pale grey; and in ſome Places whitiſh.

It is eaſy for him, from the before mentioned Directions, to know in which of all theſe States the Turf is fitteſt for his Purpoſe. While it is black and holds together, it is burnt but imperfectly; when it begins to crack and crumble to Pieces, it comes nearer to a Condition for his Service: but the true State in which it is to be uſed is, when 'tis moulder'd to Pieces, but yet retains a yellowiſh or rediſh Colour: the Aſhes are at this Time thoroughly made, and yet they retain their full Virtue. After this, every Minute that they continue on fire, they loſe ſome Part of their Goodneſs.

We now naturally are led to conſider the proper Degree of Fire, for the bringing the Turf to this State, with leaſt Loſs of the Virtue in burning.

All Violence of Heat waſtes the Virtue of the Turf, which the Farmer wiſhes to have remain in the Aſhes: therefore he is to contrive to burn them by a ſlow and mouldering Fire. For this Reaſon the leſs additional Fuel he uſes the better: and that there may be Occaſion for as little as

poſſible, he will do well to dry the Turf as perfectly as he can firſt. It is for this Reaſon alſo, principally, that the Aſhes made from rich Turf, are found better than thoſe from ſuch as is poorer, for the rich Kind conſumes by itſelf, and that ſlowly.

I have known a Farmer who thought he was doing his Buſineſs to great Perfection, in this Article, dry his Turf ſo well, and then put ſo large a Quantity of dry Furze under and between each Heap, that the whole Virtue of the Turf has been ſent into the Air, excepting what remains in all Aſhes. Every Heap has blaz'd away like a Bonfire, and the Aſhes have remain'd white, and in a Manner inſipid.

To preſerve the full Virtue of the Aſhes, a ſlow ſmothering Fire is beſt. And this the Farmer is alſo to recollect, that the Inſide of his Heaps will be always more burnt than the Outſide, ſo 'tis enough, in many Caſes, if the Outſide be well crack'd, and ready to break to Pieces with a ſmall Blow. In this, however, no general Rule can be given, for the Nature of the Turf differs ſo much, that ſome will hang together till ſtruck, when it is over-burnt, and other Kinds will break and fall in before they are half reduc'd to the proper State. I have taken the only general Method; that is, informing him of what is the right State of the burnt Turf, for giving its full Virtue. And his Eye muſt watch this, and take the proper Opportunities of continuing or ſtoping the Burning, when it is needful.

The Farmer may gueſs, by the Nature of the Turf, what Degree of Fire it will bear, and what Addition of Fuel it will want: this he is thoroughly to weigh before hand, for on this a great deal depends. The Practice ſucceeds beſt when the Hills burn juſt as long as they ſhould, and ſo may be left ſtanding whole upon the Ground; and this will depend upon the Quantity of Fuel, join'd to their own different Nature. If too much Fuel have been given them, as in the Caſe of the fooliſh Farmer before-mentioned, and they from thence continue burning within, after the very Outſide is done enough, then he is to break and ſpread them a little, ſo as to make them go out: but it is much beſt when they go out of themſelves, and remain properly calcin'd and whole: for when they are thus broke and ſcatter'd, if a windy Day come, half the Aſhes will be blown away.

We will ſuppoſe therefore, according to the Directions here laid down, the Heaps ſo well made, and the Fuel ſo juſtly proportioned to the Nature of the Turf, that the Hills are all ſufficiently burnt and ſtand entire.

In this Condition the Farmer is to leave them till thoroughly cold, and if that happen in any reaſonable Time, till there has been a good Shower or two of Rain; he is then to prepare for ſpreading of them: and for this Purpoſe he is to take the Advantage of a calm and ſtill Day.

He is to begin with paring the Surface of the Earth up to three or four Inches Depth all about each Hill, and then removing the Hill a little, he is to pare it ſomewhat deeper, juſt under its Place of ſtanding. Theſe Parings of the Ground are to be thrown upon the Hill, and all is to be broken and mix'd together.

It is proper to explain the Uſe of this Part of the Operation. I would have the Farmer receive nothing upon Tradition, but all from Reaſon. I have obſerved before, that not only the Aſhes of the Turf fertilize the Ground; but this very Act of burning; the real and actual Effect of the Fire does great Service to the Land, ſo far as it reaches. A greater Degree of Fire alters the very Quality of Earth, and renders it unfit for Vegetation, but Fire, in this Degree, only heats it enough to divide it, which is one great End of all Dreſſings whatſoever.

Now as the Earth that was under theſe Hills, and that juſt round about them, would be thus rendered more fruitful than that between one and another of them, at a ſomewhat greater Diſtance, the Land would afterwards be fruitful in Spots and Patches: or the Crop would be too rank in theſe Places, and ſtarved in others.

To prevent this, the Farmer is directed to pare away the Earth under and about each Hill; and mix it with the Aſhes of that Hill. By this Means the Quantity of theſe Aſhes will be encreaſed, and they, together with this Earth which is thus enriched beyond the reſt, will be regularly ſpread over the whole Field; and every Part of it will enjoy an equal and a great Degree of Fertility.

Some add Lime to the Aſhes, in the Quantity of about half a Peck to every Hill, ſuppoſing each Hill made of a ſingle Wheelbarrow full; or more, as the Hills are larger. They put this in under the Hill, or among the Aſhes; and don't ſtir it till Rains have come to ſlake it. This adds to the Fruitfulneſs that follows, but it is not needful; for there is enough without it: nay the Danger of a Piece of Land that has been well dreſs'd in this Manner is, that it ſhould be too rich, and make the Crop over rank. I therefore adviſe the Farmer to make no Uſe of Lime, or any other Addition to the Aſhes, except the Earth, par'd up as before; and he may be aſſur'd of ſufficient Encreaſe.

The beſt Seaſon for undertaking this Buſineſs is about the Middle of May, for at that Time the Surface of the Ground is generally in a good Condition for burning. The April Rains have made the Roots ſhoot out, and the enſuing Warmth has dry'd it. Beginning at this Seaſon alſo, he will have Time for waiting every Opportunity, to take Advantage of Weather, and all Accidents, and will have his Ground in thorough Order for his Seed.

After this burning and ſpreading the Aſhes, he has nothing to do but to plow the Land, and ſow it; and this plowing muſt be the ſlighteſt imaginable. He muſt go to no Depth, and only juſt turn in the Soil, with the Aſhes upon it, ſo as to mix all together, and then ſow his Corn.

Another Particular alſo is, that the Farmer here ſaves half the Expence of his Seed Corn. One half the Quantity that is allowed to other Lands, is ſufficient for theſe, after burnbaiting, and the Crop is very abundant. It is moſt profitable to ſow Wheat the firſt Year; and 'tis beſt to ſow it very late: the firſt Week in Novem-

BER is ſoon enough, and this Way it will flouriſh and yield a vaſt Abundance.

Few who have not ſeen the Effects of Burnbaiting, cou'd conceive how profitable a Method of Dreſſing it is. And what ſhould recommend it the more ſtrongly to general Conſideration, is, that it is not to be uſed on Lands that are good in themſelves, but on the very pooreſt and worſt, and never fails of Succeſs.

Burnbaiting ſhould never be practiſed on rich Soils at all; nor is it proper on the ſtony, gravelly, or chalky Kinds: or indeed for any Lands that have been kept long in Tillage. Every thing ſhould be apply'd to its right Purpoſe, in order to the yielding of its beſt Advantage; and the proper Uſe of this Method is, for poor, barren, ruſhy, and heathy Grounds, that have lain a long Time untill'd, and are of little or no Value.

I have given the Farmer at large, the whole Method of this excellent and uſeful Practice. He is inſtructed perfectly in the Art of obtaining, by this Means, an excellent Crop from the moſt worthleſs Land.

The Advantage is not confin'd to one Year; it will very well laſt three, and in thoſe it is eaſy to obtain, from ſuch a Piece of Ground, as much in clear Profit as would have purchas'd it at the full Value. The Huſbandman is content with this, and he leaves the Land as he found it: for the Effect of Burnbaiting does not laſt more than three Years; and at the End of that Time the Ground is left full as poor as it was before. This forced Fertility has indeed ſo thoroughly exhauſted its Strength, that it will not be fit to bear any thing afterwards, till it has had a Reſt of ten or a dozen Years.

But though the Farmer is content with this three Year's Profit, from his burnbaiting of Land, there is no Neceſſity that he ſhould be ſo, nor are his Profits confin'd to that Time, unleſs by his own Indolence. This is a Thing that has been mentioned before; and 'tis a Wonder the Farmers have not univerſally conſider'd its Importance.

Let them thoroughly underſtand this Matter. Burnbaiting, and dreſſing with Dung agree in this, that they both render Land fertile for three Years. The Difference between the two Methods is this. At the End of the three Years Fertility from Dung, the Land is ready to receive another Dreſſing; but in the burnbaiting Way it is not.

What then can be ſo plain, as that if it will not receive the common Dreſſings at the End of the three Years, they ſhould be offer'd to it in the mean Time. It will receive them if they be; and here lies all the Secret.

Dung raiſes but a moderate Fertility, and is uſed to Land that was not bad before. Burnbaiting is employ'd on Land that was good for nothing before; and it gives, the firſt Year, a prodigious Encreaſe. It might bear recruiting after this, exhauſted as it was; but after two Years more being exhauſted, without any Supply, it will not. It is then too much impoveriſh'd to receive Good from any thing, like Animals after too long an Hunger, that die when they have had Food.

Upon this reaſonable Plan I ſhall propoſe a Method to the Farmer, by which, having recover'd ſuch a Piece of Ground from Barrenneſs, he ſhall keep it good and fertile for ever after. It is no more than this.

After the firſt Crop is got in, let him prepare it for the ſecond by any common Manure. This being offer'd before it is quite exhauſted, will be readily received; and by this ſingle Act it will be brought to the Condition of other Land, and may be treated, in the ſame Manner, as a better Soil for ever, in the common Methods, and with the common Advantages.

If Marle can be had, and I have ſhewn already that Marle is to be found in moſt Places, where the Farmer will have the Induſtry to ſearch after it; let the recovered Land have a middling Quantity of Marle laid on it, between the firſt Crop and the ſecond Sowing. This will be extreamly worth the Farmer's while, for after this it will be at once in the Condition of other marled Lands; and being treated like them, will yield in the ſame Manner.

If Marle cannot be had, a common Dunging will do; or what is much better, a Compoſt made of Horſe Dung, Cow Dung, and River Mud. The Farmer may take his Time for getting this ready; and it will not fail to anſwer his largeſt Expectation.

I have thus ſhewn what vaſt Advantages ariſe from this Practice of Burnbaiting, and in what Manner they may be continued: I have obſerved that it is a Dreſſing only to be given to the worſt of Soils. But although theſe alone require it in the full Extent and Degree; yet there is no Reaſon others which do not want it ſo much, ſhould be wholly deny'd the Advantages of the Practice.

We ſee that Aſhes are an excellent Manure; and we ſee that the Heat which is given to the Earth, by the burning ſmall Quantities of vegetable Matter upon its Surface, is a vaſt Improver of its Fertility. Now Aſhes may be a very proper Manure for Lands that do not require abſolute and thorough Burnbaiting; and if we give them Heat at the ſame Time, it will certainly be better.

On this Principle the Farmer will do well, on many Occaſions, to make thoſe Aſhes upon the Land, with which he intends to manure it; and he will ſo have the Benefit alſo ariſing from this heating of the Ground. This Practice is already followed on many Occaſions, and I ſhall recommend it on ſome others. And as this does not require the abſolute burning of the Baite, or Turf itſelf, I ſhall diſtinguiſh theſe by the Name of Baſtard Burnbaiting.

CHAP. XL.

Of Baſtard Burnbaitings.

THESE Methods have been in Practice in many Places, and in all Ages, though not diſtinguiſhed by any particular Name. It might have been ſaid, and it has been ſaid by many, that the Practice of Burnbaiting is as old as any thing we know of Huſbandry; the Poet VIRGIL is quoted by every little Eſſayiſt in this Way, for deſcribing

deſcribing it, and it might be added, that all the old Roman Writers on Country Affairs have named it. But if we take in theſe baſtard Burnbaitings, the Aſſertion is much more juſt, and the Practice may well be ſaid to have been not only very antient, but in a Manner univerſal. Some of theſe Writers ſpeak indeed of burning the Soil itſelf: but they all talk of firing its Produce upon it, ſuch as dry Stubble, Haulm, and the like; as alſo of burning other Matters upon it brought thither for that Purpoſe. Theſe Practices are what I call baſtard Burnbaitings, which Term comprehends the burning the Refuſe Product of the Land; or whatſoever is brought to it, and laid on it for that Purpoſe: in ſhort, the burning any Thing except the Turf, or upper Covering of the Land itſelf; which in true Burnbaiting is cut up for that Purpoſe.

We have ſeen that this Practice was very antient; and we find to this Day that it is beneficial. Aſhes are a good Manure; but they are of ten-fold Value when made upon the Land. Men ſeem to have been inſtructed in this Practice as it were by inſtinct, for they have fallen upon it in Places where they could not have been taught it by one another.

In all the Accounts of the Practices of the East Indies, we read that in Ceylon, they burn off the dry'd Stalks of their Harveſt to prepare the Land for a next Year's Crop: and thoſe who have given us the firſt Accounts of America, join in telling us that the Natives uſed always to ſpread dry Wood over their Lands, and ſet it on Fire by way of cultivating the Ground. The Aſhes fell pretty regularly this Way; and the Ground was well and uniformly heated by the Fire, ſo that it could not fail of yielding a good Crop; and this, as it was not ſo ſevere a Practice as burning the Turf, would not be of that ill Conſequence to impoveriſh the Land for future Years.

In Places where Wood is plentiful enough, there could not be a better Method than thus ſpreading dry ſmall Wood over a Stubble Field, and burning that and the Stubble together. Let us not be aſhamed to learn even from Savages, when their Practice is founded on Reaſon, and ſupported by Experience.

I ſhall conſider this general Practice of baſtard Burnbaiting under four Heads, as it regards. 1. The burning of Sedge on wet Lands. 2. The burning the Stubble upon Corn Fields. 3. The burning any waſte Product on Heaths and Commons; and, 4. The bringing on Materials to the Land, and burning them there.

The burning of Sedge on wet Lands is a very old Practice, and has always been a very ſucceſsful one. In theſe Places the Graſs is often ſhort and ſour, and there grows a Kind of low Flag; whoſe Leaves take up more Room than all the Graſs. Theſe are uſually yellow, and look in a decay'd State; and in October or thereabouts, they become dry and ſtrawy. They then cover the Ground ſo, that there is ſcarce any Graſs to be ſeen, and they are dry enough to take Fire.

In this Caſe the Farmer is to take the Advantage of a very dry and moderately windy Day, and to ſet Fire to a whole Edge of the Field, that the Flame may be carried before the Wind. The whole Ground will be cover'd with Flame in a few Minutes, and ſoon after with a Kind of light black Aſhes. He is now to wait for the firſt Shower to damp them a little, and immediately upon this to ſow the whole Ground thick with Hay Seed.

Very often it happens that the Winds take off the whole Quantity of the Aſhes from the Ground, but even then the Advantage is not loſt, for the Heat ariſing from the burning, has killed the Roots of theſe Flags that lie juſt at the Surface, and has prepared the Ground to receive the Seed, which ſoon takes Root, and overpowers any other Growth, ſo that in Spring it ſhoots up at once, and grows immoderately. There never fails to be a very fine Swarth from this Practice, however contrary the Seaſon may have been; but if a little Rain have fallen, and the Aſhes are well waſh'd in with the Seed, the ſudden Shoot is ſurprizing; and the Weeds never recover themſelves.

In other Places of the Fen Lands where the Ground is ſpungy, and cover'd with Ruſhes, they turn up the Turf with a Breaſt Plow, and burn it on the Soil, afterwards ſowing Hay Seed inſtead of Corn. This is abſolute Burnbaiting, only as Graſs does not exhauſt Land like Corn, it has not the Diſadvantage of impoveriſhing it in that Manner for many Years after. This will continue good Paſture Ground a great while without any other Care.

This is a needful Practice in ſuch Grounds, becauſe their Wetneſs is not to be corrected by a mere burning of the Sedge; and Ruſhes are too firmly rooted to be deſtroy'd by that ſlight Method: but in the Iſle of Ely where this light Flag over-runs the Surface, I have ſeen the Practice of firing it without ſtiring the Ground, uſed to very great Advantage; and though begun there but a few Years ago, and only in one particular Place, it is becoming univerſal. The Advantage procured the other Way is greater, but this is eaſy, and it ſatisfies the Farmer.

The burning Stubble upon the Fields is an old and a common Practice, and though the Aſhes made this Way are light, and but a ſmall Quantity, yet the Heat that is thus given to the Ground, makes ſuch a Dreſſing better than the laying on four Times the Quantity of the beſt Aſhes brought from elſewhere.

Experience ſhews, that this Practice of burning the Stubble ſucceeds excellently upon thoſe Lands that are uſed to feed the Straw and Leaf, and ſtarve the Ear. The Farmer frequently finds Lands that yield a full Stalk, and a poor Ear; and others that lengthen and fill the Ear, while the Stalk is ſhort. He cannot tell the Reaſon of this, nor perhaps the beſt Philoſopher for him; but he may learn from Experience, that the burning of Stubble upon the worſer of theſe Lands, brings them into the Condition and Nature of the better.

When the Farmer intends to burn his Stubble, the firſt Thing he does ſhould be to plow up the Land under the Hedges; for it has often happen'd, that by the Wind the Flame has been driven to the Hedge, and catching hold of decay'd

cay'd Branches, has done vaſt Miſchief.

Although I have not recommended the Uſe of Lime with the Aſhes made by a perfect and right Burnbaiting, yet for this Purpoſe they are excellent, and a ſprinkling of Lime thrown among the Aſhes all over the Field, and the whole plow'd in after it has lain to ſlake with two or three Showers, is a prodigiouſly rich Manure. I have experimentally known ſo much of the Advantage of this Practice, that I ſtrongly recommend it to the Farmer.

The Benefit of burning the waſte and uſeleſs Product upon barren Commons, even without paring off the Turf for that Purpoſe, is not ſufficiently known. The Way is to ſtub up the Broom, Heath, or other waſte Matter, and pile it in little Heaps, throwing over it what Earth has been rais'd in the getting at the Roots: theſe Heaps being all prepared, are to be ſet on Fire in a ſtill Day, and left to burn away to Aſhes, which they do preſently. The Earth that is thrown upon them is well calcin'd by their burning, and though perhaps reduced to a State in which it would not be fit ſingly for the Growth of Plants, it becomes an excellent Manure.

Nothing need be done to theſe Parcels of Aſhes, and calcin'd Earth, till they have lain to be drench'd a little by the Wet. They naturally fall in tolerably regular Heaps. When they have been well wetted, the Huſbandman is to take Advantage of a dry and ſtill Day to ſpread them regularly over the Land; and then the ſooner they are plow'd in the better.

Lime is an excellent Addition to the mix'd Aſhes made by this Kind of Burnbaiting, but it has not been mention'd in the general Account, becauſe Lime is a Manure that does not agree with every Soil. The Ground in theſe heathy and broomy Commons is often clayey; and as often light and hollow. When it is clayey, the Method juſt now deſcrib'd is to be uſed without farther Addition, for Lime will never do well upon Clay: but when the Soil is light and hollow, then let the Farmer lay upon every Heap of Aſhes, half a Buſhel of good Stone Lime, mixing it a little with the Aſhes: and then let him leave all as before for the Rains to damp the Aſhes, and at the ſame Time ſlake the Lime: after which let him ſpread them as before directed, and plow all in.

A great deal in all theſe Improvements is left, and muſt be, to the Diſcretion of the Farmer: for if he do not ſuit his Manure, and his Manner of uſing it to the particular Soil he has to work upon, he does nothing even with the beſt Materials, and the moſt indefatigable Induſtry.

In all the Caſes hitherto mention'd, this laſt alone excepted, theſe baſtard Burnbaitings are only a ſlight Imitation of the real and thorough Burnbaiting, and though they may to ſave Expence and Trouble, or to ſuit particular Circumſtances, be uſed inſtead of the perfect Method, they never ſucceed ſo well. There are Caſes where the right Burnbaiting is not proper, as has been ſaid already; but wherever it is, though the Coſt be greater than that of theſe ſlighter Methods, the Conſequence makes amends. The laſt mention'd Caſe I particularly excepted; for the Lime here is a very material Part of the Dreſſing.

When this Method has been carefully executed upon a right Kind of Soil, though ever ſo barren, the Effect of the Aſhes, the calcin'd Earth, and the Lime, together with that of the Warmth given to the Earth itſelf about the Heaps is ſuch, that ſcarce any other Method whatſoever ſucceeds more perfectly, or more happily for the Farmer.

This is an eaſy and a cheap Practice. It is done with little Labour, and if the Lime be burnt by the Farmer himſelf for his own Uſe, as before directed, with very little Charge; it takes Effect upon the moſt barren Soils; nay, it is beſt of all ſuited to the very meaneſt and worſt Lands: what would the conſiderate Huſbandman wiſh more? or why ſhould not every Land Owner who has ſuch Grounds in his Poſſeſſion, order it immediately into Practice. He need not make the leaſt doubt whatſoever of a great Return.

In the laſt Place I am to mention that Kind of baſtard Burnbaiting which is perform'd by bringing Sticks, Stubble, Haulm, and other waſte Stuff upon the Ground, and burning it to Aſhes. Many have ſuppoſed that this Practice did no more Service, or was in effect nothing more than the Dreſſing the Land with Wood Aſhes, bought and brought on for that Purpoſe: ſome have ventur'd to deliver as much in print, but they are greatly miſtaken. It has been obſerv'd already, that the heating the Earth in ſuch a Degree as is done by the making ſmall Fires upon it, is of itſelf a great Aſſiſtant to its Fruitfulneſs; and this makes a very great Difference between one and the other of theſe two Practices. In this Matter the Savages of AMERICA are better Directors to the ENGLISH Farmer than theſe Writers. They dreſs their Land with Aſhes, but, as before obſerv'd, 'tis always with Aſhes made upon the Spot, ſo that the Land has the Advantage of the Heat as well as of the Aſhes.

If any one can doubt whether there be really this good Quality in Heat, for giving Fertility to Land, let him obſerve the Effects of theſe two laſt mention'd imperfect Burnbaitings. In the others, Care is taken to mix the more improv'd Part of the Soil with the leſs, and conſequently all is equally fertile. But in theſe two laſt the Aſhes alone, or mix'd with Lime, are ſprinkled and plowed in, but nothing elſe is done. Now let the Crop upon either of theſe Lands be regarded attentively, and the Obſerver will find, that although the whole Field is fertile, yet there are here and there round Spots on which the Corn is fairer and finer than in the reſt. And when he examines the Matter ſtrictly, he will find that theſe are the Spots on which the ſeveral Heaps were burnt.

The Aſhes made by that burning have been carefully ſpread; and they have therefore not been more abundant in one Place than another: to what then is this particular Fertility of theſe Spots

Spots owing? the Anſwer is very plain, for there is but one Thing to which it could be owing; it is to the heating of the Ground under and about thoſe Heaps.

Let this inſtruct every Farmer who intends to dreſs his Corn Land with Aſhes, to burn the Materials upon the Place. Practice ſhews, that the lighter theſe Materials are, the more Fertility there is in the Aſhes. Now the Stuff burnt on theſe Occaſions is much lighter than the common Billets uſed for firing. This therefore is ſome Advantage, but the heating of the Ground is a much greater.

Thus although the perfect and thorough Method of Burnbaiting of Lands have on many Occaſions a much greater Effect than any of theſe ſuperficial and imperfect Imitations of it; yet the Farmer, after this Account of their particular Uſes and Advantages, will not think the Time ill employ'd, that he has ſpent in reading this brief Account of them, ſeverally, and diſtinctively laid before him.

The perfect Burnbaiting is proper only for certain Soils, and on certain Occaſions; but the Benefit ariſing from it is ſo great, that it will grieve a conſiderate Perſon, that he muſt loſe it becauſe the Circumſtances where he would wiſh to employ it, do not perfectly ſuit. To remedy this Misfortune, theſe ſeveral different ſlighter Imitations of that excellent Practice have been laid down.

The Farmer will ſee according to theſe ſeveral Deſcriptions, in what Manner, and on what Occaſions he is to employ them: and he may have this Comfort in the Uſe of them, that when he can only employ the ſlighter Kinds, his Lands have not Occaſion for the more perfect: and that, if though additional Encreaſe be leſs, the Expence alſo is leſs which procures it.

End of the Second Book.

A COMPLEAT BODY OF HUSBANDRY.

BOOK III.

Of the Improvements of Land by Incloſing and Draining; and of the ſeveral Kinds of Fences.

CHAP.

1. *Of the great Advantages of Incloſure.*
2. *Of the more particular Benefits of Incloſure, and the Objections againſt it.*
3. *Of the ſeveral Kinds of Fences.*
4. *Of Ditches, and their Uſe in Fencing.*
5. *Of Draining in general.*
6. *Of draining boggy Lands.*
7. *Of draining fenny Lands.*
8. *Of draining flat Lands near great Rivers.*
9. *Of the Ordering of Saltmarſhes.*
10. *Of Hedges.*
11. *Of raiſing the Quickſet, for a White Thorn Hedge.*
12. *Of making the Hedge.*

CHAP.

13. *Of the Seaſons for Planting, and the Choice of White Thorn.*
14. *Of keeping the Hedge in Order.*
15. *Of the Plaſhing of a Hedge.*
16. *Of the Profit that may be had from Hedges.*
17. *Of the Sloe, or Black Thorn Hedge.*
18. *Of the Furze Hedge.*
19. *Of the Holly Hedge.*
20. *Of the Elder Hedge.*
21. *Of the Uſe of the Crab, Sallow, Alder, and Bramble in Fencing.*
22. *Of the Bank Fence, with its Plantation.*
23. *Of the Wall Fence, with its Plantation.*

The INTRODUCTION.

Of Incloſure in general.

HAVING given the Huſbandman Inſtructions for underſtanding the Nature of his Soil; and for the meliorating and enriching it by the ſeveral Kinds of Manures; we are to advance to an Improvement of another Species; that which is to be made by Incloſure: which is not only great in itſelf, but is the beſt of all Aſſiſtances to the ſeveral other Kinds.

If it be ſaid, this in the general reſpects the Land Owner, rather than the Farmer who rents his Ground, we anſwer, That it is the Purpoſe and Deſign of this Work to inſtruct both: nor is it poſſible to form a Wiſh more advantageous to this Kingdom, than that the Gentlemen who are Poſſeſſors of Land, would join with the Huſbandman who commonly rents it, in this great Undertaking of Improvement.

But though incloſing in the firſt Inſtance may more properly be ſaid to regard the Landlord, yet in general it is an Article of great Concern to the Farmer. He is to keep up the Fences, and this at a conſiderable Charge. We ſhall therefore in a great Part of this Portion of our Work, labour alſo for his Advantage.

The Benefit of incloſing is obvious: 'tis indeed ſo evident, that thoſe who have for other

Reaſons written againſt the Practice, have been oblig'd to allow it the greateſt of all others, in the Improvement of particular Eſtates. We ſee on all Occaſions, that it encreaſes the Rent of Land in a very important Manner, bringing it at once to three, four, and ſometimes to ten Times its former Price.

Every particular Inſtance that I have ever ſeen or read of it, has join'd to enforce this general Account, for no Attempt in that Way can be named, that has not enrich'd the Owner. One would wonder, that a Thing ſo plainly beneficial, is not more univerſally practiſed.

Private Eſtates lie differently, and ſome contain more, ſome leſs of enclos'd, and of common Field Land. To judge of the Quantity enclos'd, and Quantity open, we are to look into the general. England is ſuppos'd to contain more than forty Millions of Acres; and 'tis computed that about one third Part of our Land is open Field. Upon this Suppoſition, which probably is near the Truth, for 'tis hard to come at it exactly; the Rent of more than fourteen Millions of Acres of Land in this Kingdom, may be raiſed to three, four, or many more Times its Value, by this ſingle Act of Incloſure.

This is a vaſt Account; and as almoſt every private Eſtate muſt be more or leſs concern'd in it, as a Part of the general Quantity, it becomes every Land Owner to conſider it deeply, in Proportion as he happens to be more or leſs intereſted. If he can have a Method pointed out to him, this Way of trebling or more, the Rent of ſome conſiderable Part of his Eſtate without Injury to any Perſon, ſurely it is worth his while to make the Attempt: eſpecially when it is ſo eaſy, and the Event ſo certain.

It has been ſaid by ſome, that Incloſures in this general Senſe, are againſt the Laws of God; and others have imagin'd they tend to oppreſs the poor; but theſe are Points that have been debated by many as their Importance demands. It has been made appear, that if every Acre of Land in this Kingdom were incloſed, it would be for the Advantage of the poor as well as rich. However, let Humanity in this Caſe be the Guide to every particular Perſon; becauſe what might upon the whole be a publick Benefit, may in ſome Caſes be a private Crime.

Let every Land Owner who is about to incloſe, conſider what will be the Conſequences in that particular Place: if it appear that many are to be injur'd by that which ſingly enriches him, let him decline the Undertaking: but theſe certainly are Circumſtances that cannot often happen.

CHAP. I.

Of the great Advantages of Incloſure.

I Have obſerv'd, that every Land Owner is more or leſs concern'd in this great Article of Improvement by Incloſure, in Proportion as more or leſs of his Land lies open; and I am aware it will be objected by many, who ſee the Advantages of that Practice very plainly, and have Land enough to improve by it, that in ſome Places the Soil is ſo bad, that it is not worth the Expence; and in others, that as the Lands have lain open from Time immemorial, the common People will not ſuffer it.

The Thing is of ſo much Conſequence, that every Objection againſt it ought to be anſwer'd. Thoſe which are made againſt the general Practice, have been already taken Notice of in the laſt Chapter; it is fit theſe ſhould be conſider'd as ſeriouſly, which regard every particular Attempt. Such a general Practice muſt be begun and carried on by Particulars; therefore they ought in all Reſpects to be ſatisfied where there is Ground to do it.

As to the firſt Objection, the Barrenneſs of the Ground: it is a very common and a very natural one: but all that is common and natural is not juſt. A great deal of Land is called barren, that would have a better Character under good Management. I will be bold to ſay from what I have ſeen, that nine-tenths of the Land in England that is called ſo, and left waſte at preſent, might be cultivated by induſtrious and intelligent Perſons, with great Profit.

It has been ſaid, in the Beginning of this Treatiſe, that every thing may be cultivated except naked Rock, and of that we have very little in this Kingdom. What has been there advanced is founded on Experience; and he who ſhall think it worth while to undertake the Improvement of the worſt Soils heartily, and begin with Incloſure, will give his Deſcendants cauſe to bleſs thoſe who ſet him on the Trial.

To encourage the Perſon who has barren Lands to attempt this, let us turn his Eye upon thoſe Tracts of Sand which cover ſome Parts of Suffolk, and the Edge of Norfolk; nothing that can be call'd a Soil, can be ſo barren as theſe, and yet they are cultivated, where People have Spirit and Reſolution, to a very fair Advantage.

In ſome of theſe Places the Surface of the Ground is a naked looſe Sand. There is no Mixture of Earth, or any thing elſe, to be ſeen in it; and no Weed, not ſo much as a Blade of Graſs is to be found upon it for Miles together. In the open Places it is moveable, like the Sands of Arabia, by the Winds; and is carried in great Quantities, like Waves of Water, before every hard Gale. No wonder nothing grows upon it; for this ſingle Circumſtance muſt prevent that entirely.

Nothing can be pretended to be more barren than this, except bare Rock; yet they find the Way to render it fertile. They ſow Hay Seed upon it in a calm Day, and immediately cover this with Furze-Buſhes, which they ſtake down upon it, to prevent their being blown off. The Covering not only keeps the Sand ſteady, but light as it is, it produces ſome Moiſture, as there will be on all Ground that is cover'd. This ſoftens the Seed, and it ſoon ſhoots. After a little Time the Roots ſpread, and intangle in their natural Way, and hold down both themſelves and the Soil, till it is cover'd with a tolerable Sward, and fix'd from that Motion it had before.

This is done, and tolerable Paſture is produced out of the moſt abſolute Waſte. We propoſe

propoſe thoſe Things which are done on ſuch Occaſions, not only for the Farmer's or Land-owner's Imitation, but for his Improvement. From this the Owner may ſee that he needs not ſuppoſe any Part of his Eſtate barren, from this which is the worſt Fault it poſſibly can have; and we ſhall ſhew how all others may be remedied, and how moſt of them are remedied in one Place or other.

He who undertakes the Study and Practice of Huſbandry, upon the Plan of this Work, will not ſtop his Endeavours at what he has ſeen done by others. We have already acquainted him what may be done in the Improvement of Soils, and for what they are ſuited; upon theſe Principles he will turn the Suffolk Method to a much greater Account.

Let him who has ſuch a Piece of Ground, begin with it as they do there, but let him not ſtop where they do. In the firſt Place, when he has thus cover'd the Sand with a Sward, let him encloſe it with a thick Hedge, to prevent the Sand from the neighbouring Ground being driven upon his Crop, and burying it. He will thus ſecure what he has got, and make it a laſting Advantage.

Again let him conſider, that when he has a Piece of ſandy Ground encloſed, Graſs is not the only Produce he may make it yield. Carrats thrive better in this, than any other Soil whatever; and Turneps will ſucceed in it very well.

Here are two Articles by which he may very well pay the Expence of his Incloſure, in a few Years, and all that Time be improving the Land. But that is not all.

We have ſhewn, in the preceeding Part of this Work, in what Manner ſandy Soils, even the worſt of them, are to be brought into a Condition to bear any Kind of Corn or any Crop whatſoever, to great Profit, and with great Certainty. Now what will improve and enrich a ſandy Soil, which has ſome Mixture of Earth, will, in a fuller Uſe, give Fruitfulneſs to the bare Sand itſelf; this follows from the Nature of the Practice itſelf, which conſiſts chiefly in adding ſuch Matters as alter the very Nature of the Ground.

Now upon this Principle, as ſoon as the Land Owner has been at the Expence of an Incloſure upon the moſt barren Sand imaginable, let him not depend upon the Hay that it will yield, which is little, or upon the Paſturage it will afford to Cattle, which, though very ſweet is alſo moderate in Quantity; nor let him fix himſelf to any one Growth.

Let him begin to improve it upon the Plan, and by the Methods, laid down in our firſt Book, and fifteenth Chapter, for the Improvement of a ſandy Soil; and when he has by a careful Management brought it to the Condition of a better Ground, let him ſow it in the uſual Manner; and he will reap Wheat, Barley, Rye, Beans and Peas from it, to the Aſtoniſhment of his Neighbours, and perhaps to their Imitation.

This is not to be undertaken in ſuch Places, but by beginning with Incloſure, the Expence of which will be ſomething; but a few Crops will repay it; and the Land will be render'd valuable for ever.

If this may be done by the Aſſiſtance of Incloſures in the worſt Soils, for none can be more barren than what has been here propoſed for a Trial; it is very evident that upon a better Land, the Advantage will be greater. What was propoſed here was to anſwer the Objection, That ſome Parts of an Eſtate may be barren, and not worth incloſing; which we hope is thus ſhewn to be altogether a Miſtake. Certainly it is ſuch, and every one who ſhall be induced to make the Trial, will find it beneficial.

Without Incloſures, this is in ſuch Soils altogether impracticable; and indeed the Benefits of a perfect and expenſive Dreſſing of Land, are never thoroughly aſſured to him who is at the Expences and Trouble, but in Lands that are incloſed. This therefore is a great and a reaſonable Motive for extending the Practice.

As to the Oppoſition of the common People, which is the ſecond Objection, that may alſo be anſwer'd with Truth and Candour. Where the incloſing will be a real Injury to the Poor, the Landlord has been already adviſed to let it alone; but this can happen only in a few Inſtances. In all others, where their Oppoſition ariſes from Obſtinacy and Folly, let him guard againſt its Effects by ſetting out in a proper Manner.

Dry Hedges are eaſily laid flat, and Quick-ſets pulled up, and this He may always expect will be done who oppoſes Prejudice, let him therefore make his Fence by a Ditch ſeven Foot deep, and as many wide. They will be ready to throw the Earth into this again, and fill it up: 'tis true, but he may prevent that in Time, by ſpreading the Earth as it is thrown out upon his Land. This will ſerve as a Manure to the Soil, and though Paſſion might have led the Mob to throw in the Bank if it had been left, they will not be at the Pains of digging for that Purpoſe: they will not have Opportunities of doing this in ſecret, and they will not dare to do it openly.

Thus will the Effects of Malice be prevented; and the Benefit of the Expence and Labour aſſured to the Proprietor. They will very ſoon be repaid by the Produce; and if it ſo happen that Water can be got into the Ditch, the better. After a few Years, Things will be left quiet, for Cuſtom will prevail one Way as well as another, and a Quick may be planted, which will thrive leiſurely, and enſure all the Advantages of a regular Incloſure.

CHAP. II.

Of the more particular Benefits of Incloſure; and the other Objections made againſt it.

THE Improvements which have been mention'd in the preceeding Part of this Work, are very numerous, as well as great. The leaſt and ſlighteſt of them will very well anſwer the Expence of the moſt coſtly Kind of Incloſure, in the Compaſs of a few Years; and there is no Kind of Land whatſoever, but will by means of Incloſure, be render'd capable of one or other of thoſe Improvements.

This is a certain and unqueſtionable Truth; and this at once ſets the Buſineſs of Incloſure upon its proper Footing, ſhewing every Land Owner, in every Circumſtance and Situation whatſoever, that it is to his Intereſt to incloſe. Things plain in themſelves become yet plainer by Inſtances; and every one of theſe that can be produced, will ſerve to ſtrengthen the Cauſe in Favour of this Practice: it is a very bold Thing to advance, but it is as certainly a Truth, as ſaid before, no Perſon ever ſet about Incloſure upon proper Knowledge, and with due Induſtry, who did not vaſtly profit by it.

This Practice not only makes Land yield greatly more; but it enſures to the Owner his Property and all its Advantages, as it prevents thoſe innumerable Treſpaſſes and Injuries which are continually happening in common Lands.

It gives a Man Liberty alſo of making whatſoever Alterations or Improvements he ſhall chooſe, upon his own Land; he may plant and ſow what he pleaſes, and in whatever Manner he pleaſes, upon his Ground, when thus ſeparated from the common Quantity; which he cannot do without a thouſand Inſults, Interruptions, and Inconveniences, from the Malice, Envy, or Folly of his Neighbours, while it lies open.

Theſe are not imaginary Advantages: all Counties, and all Times, have allowed them. We read in the antient Books that mention Huſbandry, of incloſing as the next Thing to plowing; often, in more improved Trimes, as prior to it: and in all known Countries, from the earlieſt Time to the preſent, incloſed Lands have been held more valuable than the open.

Beſide the political Advantages of Incloſure, in aſcertaining a Man's Property, and ſecuring to him the Fruits of his Induſtry uninterrupted, there are ſeveral that may be called natural. I have already mentioned the Uſe of Hedges in thoſe ſandy Weilds of Suffolk, to keep off Loads of the looſe Covering of the barren Parts, from overwhelming the fruitful: but in all Places, in the beſt as well as worſt Counties, they are of great Service to the Crop, of whatſoever Kind. They defend the Crop from the Fury of the Winds, and, in a great Degree, from thoſe cold and nipping Blaſts which are ſo miſchievous in the early Part of the Spring. An incloſed Piece of Land is always quieter and warmer than a Piece in an open Field of the ſame Soil and Condition. This is very obvious to Reaſon, and is confirmed by Experience.

Incloſure preſerves, in a great Degree, the natural Heart of the Land, and that Richneſs which may be added to it by proper Manures. For it is found that the ſame Quantity of Manure will do twice the Service upon a quiet, warm, and ſheltered Cloſe, than it will upon an equal Quantity in an open Field, where it is liable to all Injuries. It is certain and well known, that an incloſed Land yields a much larger Crop of any Kind of Corn, from the ſame Seed and the ſame Dreſſing, than it will in an open Field: And as to the Graſs for Paſturage or Hay, there is no Compariſon between the Quantity growing on incloſed and common Lands. The Hedges alſo which make the Incloſure, if rightly managed, as we ſhall direct at large in the ſucceeding Chapters, are, in themſelves, a great Advantage and Profit. They ſerve for a Shelter to the Cattle that feed in thoſe Fields; and they ſupply the Farmer with Wood for all his neceſſary Purpoſes; and may be made in many Places to yield alſo valuable Fruit.

Theſe added to the many other Benefits ariſing from Encloſure, already mentioned, we may reaſonably hope will lead all to a due Senſe of the Importance of this great Article in the Improvement of Land. Nothing more is wanting, certainly, to convert the naked and ſtarved Parts of Wiltshire, Hampshire, and ſome of our other Counties that might be named, into the ſame Condition with the moſt rich and improved Parts of Buckinghamshire, and Hertfordshire; and to make the common People of one as happy as thoſe of the other. For whatever Pretences may be made of the Oppreſſion of the Poor, by the encloſing of Lands, this is certain, that they no where are ſo happy as where the Land, in general, is under Incloſure, and no where ſo miſerable, poor, ragged, and idle, as in thoſe Places where moſt of the Land lies in common.

All was once open, and the civilizing of People, and improving Lands by Incloſure, here came together. Thoſe who firſt ſettle in a Country find it all open. They, by Degrees, appropriate and incloſe: and why ſhould not that which is found ſo beneficial in the firſt Steps to improving a Country, be carried throughout every Part?

Certainly every Man would wiſh, and muſt naturally deſire, to have that which is his own entirely his own: and this can only be by Incloſure. That Land cannot be perfectly a Man's own, which is not entirely in his Power. And that is not ſo in his Power which he cannot manage as he pleaſes, and cultivate when, how, and in what Manner he pleaſes. How can that be entirely a Man's own, where the Profits of his Labour and Expence are not aſſur'd to him; where every ſtray Beaſt from the Highways and Commons, may walk in and tread down his Crop: nor can that Land be ſaid to be perfectly under his own Management, which he is obliged to ſow and reap at the Time others do, whether he will or not; and to keep Time with them in all other Particulars, when he knows how, by another Conduct, to have greater Profits.

That what is urged here in Favour of Incloſure, is not from Fancy or Prejudice of Opinion, is evident from what we ſee daily of the Effects and Conſequences of that Practice. We may eaſily direct our Eyes to Places where, in the Memory of ourſelves or our Fathers, Incloſures have been made from the common Fields. Let us fairly examine together the Condition of what is incloſed, and what lies common. The Land is the ſame, an Hedge only parts it; yet we find univerſally, that the Crop is vaſtly greater in the Incloſure, than in the common Fields: nor can there be any Cavil juſtly rais'd againſt the Concluſion from this, by alledging that more is beſtowed, perhaps, in dreſſing the incloſed Piece of Ground. 'Tis plain, by Peoples continuing to dreſs it at ſuch Expence, that the Profit anſwers. But the general and unanſwerable Argument is,

that

that ſuch incloſed Lands are of more Value than equal Quantities upon the common Field. The Advantages of the Crop ſoon pay the Expence of making the Incloſure; and the Value of the Land is made much greater for ever. This is ſo plain an Argument that it admits no Diſpute.

We ſee vaſt Quantities of Land lie open in many Places, where it is of very little Value: We have ſeen, from Time to Time, Parcels taken from this and incloſed, which, upon due Dreſſings, have, in a few Years, paid back all the Expence of Incloſing and Improvement. Can there be any Reaſon aſſign'd why this ſhould not be done every where.

The Reaſons that have been pretended againſt it are either falſe or frivolous. Many of them have no Foundation in Fact; and others which are true, and are a general Grievance, may be eaſily removed.

In the firſt Place, it is not true that the Poor would be injured by a general Incloſure of all common and waſte Land. If there be particular Inſtances in which they would ſuffer, theſe ſhould be particularly conſidered, and Amends made to the Sufferers. In general the Advantage that a poor Man has by keeping two or three ſad Creatures of Cattle, of any Kind, upon the common Land, are not at all equal to what he and his Family would find, by being ſure to know where to get conſtant Employment as Labourers. This Privilege is indeed a Source of Idleneſs: and that can never be for private nor publick Advantage.

Upon the Edges of all great Commons we ſee a miſerable Set of Cottagers. Hunger is in their Faces, and Miſery upon their Backs: they idle away their Time in tending their own and other People's Cattle; and breed their Children to this poor Employment. The Profits of this are not at all comparable to what they would have from the common Price of their Labour and their Childrens. And if theſe Lands were incloſed, they would be at once compelled to Induſtry; and always found in Employment.

The great Number of Claims and Titles for almoſt every Piece of common Field and waſte Land in this Kingdom, is indeed likely to be always, as it has been often, an Hindrance to this great Improvement by Incloſure. Among theſe ſeveral People one Man is obſtinate, and will not comply; another is under Age and cannot: Theſe are real Objections, but they are eaſily removed.

Is what has been ſaid upon this Subject true or falſe? certainly it is true! being true, is it not ſufficient Proof of the general and univerſal Benefit of Incloſure? if ſo, why ſhould not a Power be allowed to the Majority of Proprietors, by Parliament, as in other Caſes, to which the few who are fooliſh and obſtinate, muſt ſubmit: and in virtue of which, a Liberty ſhould be given to ſome to treat for Minors; and in all particular Caſes Proviſion made for thoſe who ſhall fairly ſhew themſelves to be aggrieved.

This appears to be a reaſonable Plan: and the Conſequences of it are certain. They are a great Addition to the Value of Land; and a conſtant Employment for the Poor and Induſtrious. The Highways, which are at preſent ſo wide in theſe open Fields, and deſtroy ſo large Quantity of the Land, might be reduced there as well as in other Places; and no Prejudice or Inconvenience to any could ariſe from it there, any more than elſewhere. A great deal of Land would be then recovered from the moſt needleſs Waſte imaginable; and its Value would be made much greater by the ſame Practice.

It is not only certain that Incloſing Land any way is an Advantage in every Place, but 'tis equally true, and is ſupported by the ſame Experience, that the ſmaller the Incloſures are ſeverally made, the greater is the Improvement. This is conformable to Reaſon; for Incloſures of a large Extent are leſs ſheltered by their Hedges, and have leſs of all the other Benefits of Incloſure, as they approach nearer to the Nature of common Fields; the Borders of all which are terminated by Hedges ſomewhere. And, on the contrary, the more of theſe Incloſures are made, and the ſmaller the Parcels of Land contained within them, in the greater Degree it has the Benefit of all that Practice; and, accordingly, the larger Returns it is conſtantly found to make, whether Corn or Paſturage.

The encreaſed Value of Land by this Practice, always keeps Pace exactly with theſe Advantages, the ſame Quantity of Land, upon the ſame Soil, will always let for a larger Sum if there be many, than it will if there be few Incloſures; that is, it will fetch the more Rent, the more Parcels it is divided into. Objections might be ſtarted againſt this general Account, from particular Inſtances, but they will be conſider'd ſeverally hereafter: this is ſaid generally; and it has fewer Exceptions than almoſt any other general Rule; though, from its extenſive Compaſs, it cannot but be liable to ſome.

In good Meadow Land there is ſometimes a Loſs by having too many Hedges, by the Quantity of Graſs they ſpoil by their Shade, and their Drippings; but even this Diſadvantage is owing to the Want of due Knowledge in the Art of Fencing. We ſhall ſhew hereafter, that even in theſe Caſes, if proper Trees are planted, their Produce will be worth more than the Graſs they injure.

Objections have alſo been ſtarted againſt Incloſure in Corn Lands, from that common Opinion that Wheat, in incloſed Lands, is more ſubject to Blaſts and Mildew than in the open Fields. Of this we ſhall treat at large hereafter, when we come to ſpeak of the Diſtemperatures of Corn. For the preſent it is ſufficient to ſay, that theſe Accidents are not the Effects of Incloſure, although, perhaps, they are more frequent in Incloſures, than in open Fields. We ſhall, hereafter, ſhew their Nature and their Cauſe; and propoſe ſuch Methods as, with due Obſervance, will not fail to preſerve a Crop from them. In this Place it need only be farther ſaid, that Wheat is always as liable to blaſt and mildew upon an open Field, as in an Incloſure, provided the Land be as rich. This is a certain Truth, confirm'd by abundant Experience; and as there are Methods of Prevention in each Caſe, there is not the leaſt Juſtice in uſing this Accident as an Argument againſt Incloſure.

It is ſaid alſo, That the Number of labour-

ing

ing People is not ſufficient for the dreſſing of all the Lands in the Kingdom, ſuppoſing they were all incloſed. Let this be fairly conſider'd, for it has ſome Weight. 'Tis certain that the ſame Quantity of well-incloſed Land demands a great many more Workmen than when open. The Cauſe of this is ſeen in the Account given already of the Culture of incloſed and open Fields, the fallowing of one, the conſtant working often of the other; and the ſeveral other Differences that will be ſhewn in their proper Place. But this Article of incloſed Lands employing a greater Number of People, is one of the greateſt Arguments in its Favour. As to there not being enough of them at preſent; all the Land of the Kingdom could not be incloſed at once; ſo they would not be all wanted at once. They would riſe as the Occaſion roſe for them. At preſent all other Employments are over-burthen'd with Numbers. The Tradeſmen ſtarve from the Multitude in every Buſineſs: a better Application to Huſbandry would take off theſe redundant Tradeſmen, and would employ thoſe Multitudes, who, becauſe they cannot get Bread at their ſeveral Profeſſions, rob and ſteal.

Here then are all the material Objections that have been made to the Incloſure of Lands, ſtated in their utmoſt Force; and every impartial Perſon will be able to judge, whether the Anſwers propoſed againſt them be or be not ſatisfactory in the Eye of Reaſon.

The Farmer, or Land Owner, who is about to incloſe, muſt know, that general Rules cannot ſuit all particular Caſes; therefore he is not to go to work raſhly, on ſeeing the Utility of the Plan, but to follow us, ſtep by ſtep, through this important Part of our Work; in which we ſhall ſhew him, that though all Incloſure is profitable in all Places, yet Incloſure of Meadow Land is one thing, and of Corn Land another; and impart to him the Reaſons of this Difference; and the Conduct he is to follow.

With reſpect to the ſtale Objection, that there are Lands which cannot be incloſed, becauſe Trees or Shrubs will not grow upon them, we ſhall ſhew him who makes it, in the Courſe of this Book, that Ignorance is oftener the Parent of this Excuſe than Knowledge. That all Trees, or Shrubs, are not ſuited to all Soils, every Child knows: but there are ſome ſuited to almoſt every Kind, and theſe ſuch as an ingenious Contrivance may work into Hedges. Where Trees will not thrive at all, there are other Kind of Fences to be made; and, in general, Nature, in thoſe very Places where ſhe denies Growth to the one, has made Proviſion of Materials for the other.

This is certain, Incloſure is always profitable; and there is no Kind of Land whatſoever, that may not be incloſed by ſome Fence or other, with Profit to the Undertaker. The beſt Methods of doing this will come next into Conſideration: the ſuiting the Fence to the Land, and the making and preſerving the ſeveral Kinds, will be treated at large in the following Chapters.

CHAP. III.

Of the ſeveral Kinds of Fences.

WHoſoever has a Piece of Land which he intends to incloſe, muſt remember what has been ſaid already, that every Kind of Ground will not admit of every Kind of Incloſure: but that there is no Land whatſoever that will not admit of ſome one or other, of the ſeveral Sorts of Fences needful to that Purpoſe.

When the Soil is too barren for the Growth of an Hedge, there is often Stone ready for the building of a Wall: and when it is too damp for the thriving of thoſe Shrubs, which uſually are planted for that Purpoſe, the very Water that denies Recourſe to this common Method will fill Ditches, which will anſwer the Purpoſe.

The firſt Thing therefore is to examine the Nature, Soil, and Situation of the Ground that is to be incloſed. Here is choice enough of Ways to do it; but a prudent Election muſt be made among them: for a Miſtake in the ſetting out will overthrow all the Expectation.

He who ſhould plant Hawthorn in a Fenn, or dig Ditches on a ſandy Hill, muſt be at once diſappointed and laugh'd at. One will rot, and the other be fill'd up. Neither can at all anſwer the Purpoſe. But that is no Proof that Incloſure, properly conducted, would not have ſucceeded.

Not only Corn Lands, but Meadow and Paſture Ground of all Kinds and Denominations, fall within the Reach of this great Benefit of Incloſure. Theſe laſt are principally diſtinguiſhed by their Degree of Moiſture. Thoſe which lie low, and within the Reach of natural or artificial Overflowings, are called wet Meadows or Paſtures; and thoſe which have a lighter Situation are called dry Meadows, or, more commonly, dry Paſtures. Some confine the Term Meadows to the wet, and Paſtures to the dry; but this is not the uſual Senſe of the Words. Beſide theſe there is another Kind of Meadow, or Paſture Ground, which is damp or wet from its own Nature, not from the Accident of being overflowed, at Times, by Rivers, naturally or artificially. This, when it is the wetteſt of all, is what is commonly called Bog; but it is not all of that Kind.

Theſe are the three great Differences of Meadow or Paſture Ground: and according to theſe thoſe Lands are to be encloſed in ſeveral Manners: all will have great Benefit by Incloſures, but there will be vaſt Advantage in ſelecting the proper Kinds.

In the dry Paſtures on an hilly Situation, Hedges are the proper Fences. They are of vaſt Service, beſide their ſheltering the Cattle, in that they defend the Graſs from the Summer Heats, and ſhelter it in the Spring from the drying Winds, that, in open Places, nip it while it is young and tender. For this Reaſon, the ſmaller the Incloſures are in dry Soils, and on hilly Situations, the better the Paſture thrives. This may be ſeen abundantly in all the hilly Paſtures of our improved Counties. All is freſh in theſe ſmall Cloſes, while the Graſs is poor, ſpare-

ing, and burnt up in the opener Paſtures. The Hedges alſo, when well form'd, are of Value for their Produce in needful Wood: and Timber or Fruit Trees grow well in them in moſt Places.

The wet Meadow requires Choice in the Shrubs that form the Hedge, and ſuch as are proper thrive ſo faſt, that the Profit ariſing from them is very conſiderable: in theſe the Incloſures need not be ſo ſmall; for lying low, and being well water'd, they are better defended in their own Nature both againſt the Winds and Sun.

For the laſt or wetteſt Kind of Paſture Land, Ditches ſtand in the Place of Hedges. They eaſily fill with Water, and are a very ſafe Fence. Beſide that, if well contrived, they at the ſame Time that they incloſe, aſſiſt greatly in draining the Land. Of this we ſhall treat particularly in its Place.

Thus we ſee that a proper Regard being had to the Nature and Situation of the Ground, Fences may always be had beſt of one Kind or other. The Quickſet Hedge will thrive in many Places, where few imagine, but this requires a Degree of Knowledge with which the Generality of Huſbandmen are not acquainted, but which we ſhall endeavour to convey to them in the plaineſt and moſt familiar Manner. In Places where the Hawthorn will not thrive, or indeed live, there are other Shrubs that will ſucceed very well, and make a good Fence. Where nothing of this Kind can be uſed, the Earth will yield Stone for Walls, which may be built at a ſmall Expence; or it abounds with Water for Ditches: and where none of all theſe can be had, Banks of Earth may ſupply the Place, and anſwer the full Purpoſe. The Perſon who is inclined to incloſe, can never therefore be at a Loſs for a Fence, provided he ſets out with a competent Knowledge in the Nature of the Undertaking. We ſhall endeavour in the ſucceeding Chapters, to give him the Rudiments of this Knowledge; and to inform him ſeverally of the proper Fences for all Kinds of Ground; and of the beſt Methods of making and preſerving each.

CHAP. IV.

Of Ditches, and their Uſe in fencing.

HAVING enumerated the ſeveral Sorts of Fences, and the Lands to which they are moſt naturally ſuited in their different Kinds, we come to the more particular Conſideration of each; and to their Uſe; and the Manner of making and preſerving them. In this Deſign we naturally begin with Ditches, as they are the moſt cheap and eaſy: and as they lead not only in ſome Reſpect to the making the others; but alſo to that very conſiderable Article, the draining of Land, which falls as naturally as it does properly, under Conſideration afterwards. From theſe we ſhall advance to the more complex and difficult Kinds made of Quickſets: this naturally leading us to the Plantation of Trees in thoſe Hedges, and their Plantation to that of Coppice and Foreſt Trees, in the regular Courſe of our Work.

Fencing by Ditches is the leaſt expenſive of all the Kinds, the ſooneſt made, and the eaſieſt to keep in Repair: but then it is only to be done in marſh or wet Land, or in the wetteſt Kind of Meadow or Paſture Land before mention'd. The Incloſer, who has Ground where there is Plenty of Water, cannot ſo well uſe any other Kind: but let him be ſure that this is the Condition of the Land; for he who ſhould dig his Ditches, and not have Water for them, would throw away a great deal of Expence, and make a very fooliſh Figure in the Eye of his Neighbours.

To know whether a Piece of Ground is fit for this Kind of Fence, the Owner muſt examine not only whether it be wet and damp, for that many Lands are at certain Seaſons of the Year, or occaſionally by Accident; but whether it be naturally and conſtantly ſo at a due Depth. Let him examine from what Source its Wetneſs ariſes, and whether this be continual; or be of ſuch a Kind as will afford a ſufficient Supply of Water for the filling his Ditches.

If his Neighbours have Ditches by way of Fence, let him examine into their State and Condition. Firſt let him ſee whether they anſwer their Purpoſes. If he finds they do not, let him conſider why: if they do, let him ſee whether they are likely upon an impartial Survey of the whole, to anſwer his Purpoſe in the ſame Manner.

If Ditches have been uſed Time immemorial in the Neighbourhood, and yet do not ſucceed ſo well as might be wiſh'd: let him enquire whether the Failure be owing to Nature or Neglect. Whether they have not been dug too ſhallow; and whether they do not fill up by Weeds, or by the Swelling of the Soil; which in very boggy Ground is frequently the Caſe.

If it appear upon the whole, that their imperfect Succeſs is owing to any natural Cauſe, let him not attempt the ſame Kind of Fence upon his own Ground, for this is a Point in which Nature will not be conquer'd. If there be not a Supply of Water, all his Art cannot in theſe Caſes bring it.

On the other hand, if he find their bad Succeſs is owing to ill Management, let him learn even from their Errors, and by avoiding them in his own Work, aſſure himſelf of that Succeſs which Nature allows. If the Fault be in the digging them too narrow, or too ſhallow, let him make his broader and deeper; if in the preſerving them, let his Care be doubled. Did theirs ſucceed at firſt, but afterwards fail when choaked up with Weeds? let his be kept as clean always as at firſt: and in the ſame Manner let him avoid the other Errors.

If he find the Ditches ſucceed well on his Neighbours Land, let him, before he ſets to work, examine ſtrictly whether his own Ground be of the ſame Kind: for often Fields that lie very near, differ very greatly. The Fen Lands in Lincolnshire, Northamptonshire, and the Iſle of Ely, terminate abruptly. Ditches are the only Fence they have in many Places on theſe Lands, but he would be ſtrangely fooliſh who ſhould attempt the ſame Fence when out of their Diſtrict, though ever ſo cloſe upon the

Edge

Edge of it. No more than a careful Obſervation is neceſſary, however, to determine this; for, though the two Lands lie ever ſo cloſe, the Difference between them is palpable.

If there be no Ditches made by way of Fence in the Neighbourhood, and yet the Land ſeems by its Likeneſs in Soil and Situation, to thoſe where they are uſed, to be fit for them, let him examine carefully where Holes have been dug by Accident, or with other Deſign, whether Water comes into them, and remains in them. If he find it comes in naturally and freely, and remains there tolerably well, let him ſet the Example by a fair, though not large Trial; and if it ſucceeds, he will both continue it himſelf, and lead others to imitate it in larger Works.

When the Land lies flat, when it is wet below, and the Water that ſtands any where upon it, becomes foul and reddiſh; when the Soil is black and mellow, and in many Places ſhakes or moves under the Feet in walking, there is generally Water for Ditches, and theſe are the Fence Nature points out; for there is neither Stone in the Ground for Walls, neither has the Earth a Firmneſs for Banks, neither will a Quickſet grow there. Nature in theſe Caſes points out to the Incloſer what he is to do, for ſhe leaves only one Thing that he can do. He is to dig thoſe Fences which he can neither raiſe nor build; and there are ſufficient Advantages in this Practice: For beſide the Cheapneſs of the Work, the Soil cutting very eaſy, what is thrown up is of Uſe; ſometimes more, ſometimes leſs, according to its Nature.

In large Commons theſe Ditches run into one another; or all the leſſer into one larger, which at length communicates with ſome other Water; but in this Caſe the Water is apt to grow very foul, in the leſſer Ditches eſpecially. The happieſt Situation is where every Ditch can be carried ſtrait down to ſome River. There the Water is more conſtant, and is always ſweet. Theſe may be bank'd upon Occaſion with their own Earth; and if there be any Danger of the Cattle from one Paſture, gettting into another by wading over the Mouth of the Ditch, no more is neceſſary than the running a Rail along on each Side into the River, to a certain Depth, and they will never attempt to ſwim round it. This is the Practice all along the River Nen in Northamptonshire, and ſucceeds perfectly.

In Marſh Land in general this Sort of Fence does as well as any; and in many Caſes it is greatly preferable to any other. About ſix Foot is a proper Width for theſe Ditches, and they ſhould be about ſeven in depth, that there may ſtand four or five Foot Water in them uſually; that in Droughts there may always remain ſome, and that they may hold two or three Foot perpendicular more in Overflowings, without running over upon the Land. By this Means they will ſerve as a good Fence at all Times, and not be liable to Accidents from ſmall Occaſions.

When a Fence of this Kind is made, a little Care will preſerve it, but that Care muſt be uſed, otherwiſe it becomes preſently over-grown and uſeleſs; or what is as bad, the Weeds cover it ſo thick, that Cattle attempting to walk over fall in, and are not able of themſelves to get out again. This is a common Accident on the careleſs Peoples Grounds in the Iſle of Ely, but it very ſeldom happens where Things are better regulated. Weeds are very apt to grow in theſe ſtill Waters; and the Soil is ſo ſoft, that the Banks and Edges of the Ditch are eaſily broke, and ſpoil'd: but in the very worſt of theſe Places, when the Ditches are properly clean'd, this Accident ſcarce ever happens. When the Water is tolerably clean, and the Bank ſtrait and ſteep, there is hardly any ſuch Thing to be heard of as Cattle falling in.

Theſe Fences do not anſwer the Purpoſe of a Hedge in defending the Graſs from the ſcorching Sun, or parching Winds; but then the Moiſture of the Earth in all theſe Places where ſuch Fences are proper, or but practicable, anſwers the ſame Purpoſe, and renders ſuch Defence unneceſſary. And at the Time as this Moiſture is naturally too abundant in ſuch Grounds, the ſame Ditch which ſerves for a Fence, anſwers in ſome Degree the Purpoſe of a Drain. I have obſerv'd, that the Water is to ſtand in the Ditch two or three Foot below the Surface, and in this Caſe, which is commonly about the Mark, the uppermoſt two Foot of the Earth is drain'd in a great Meaſure by it, and this Depth takes in all the Soil; all that has any Thing to do with the Growth.

This is a very important Circumſtance, and Experience confirms it. It will be explain'd more at large in the next Chapter, which treats of Draining; but 'tis certain thus far, that ſo much Good is to be done in many Situations by the Ditch fencing alone, that the ſame Ground which lying open is wet and ſhakes under the Feet, and receives their Impreſſion when one treads upon it, will upon the dividing it by a good Number of Ditches, be render'd firm and ſound; and its Product in all Reſpects better. This ſhews that in dividing and incloſing Land by Ditches as well as Hedges, the ſmaller the Incloſures are generally made, the better.

The Earth that is thrown up in digging of theſe Ditches, is a very conſiderable Quantity, and according to its Nature, or the Circumſtance of the Place ſerves different Purpoſes. Sometimes the whole, and ſometimes a part is requir'd for banking at the Edge of the Ditch itſelf. The Earth itſelf is ſometimes entire fine Mould, and not unfrequently in theſe wet Lands, it is either a true Peat, at ſome little Depth, or is ſo intermixed with Roots, that it will make a Kind of Peat at the Surface. In Lincolnshire they cut it for this Purpoſe into proper Pieces, whether it be of the better or worſer Kind; and burn it either alone or with dry'd Cow Dung: and the fine black Mould that is dug up is excellent to mix with Dung for the manuring of the dry Corn Lands.

CHAP.

CHAP. V.

Of Draining in general.

FROM the Conſideration of fencing by Ditches, we are naturally led to that of draining, as it is a Practice uſed on the ſame Kind of Lands, and has its Foundation in the ſame Courſe.

The Lands which have Occaſion for draining, are always ſuch as admit no other Fence but that by Ditching, for they are too wet for Quickſet Hedges, and too ſoft to bear the Weight of Walls; ſo that nothing rais'd upon the Surface can anſwer the Purpoſe.

Theſe Lands are of two Kinds, their Difference ariſing principally from their Situation: the one Sort lie between Hills, or upon ſome Level on their Sides, or even on their Tops in ſome Places. Theſe are called by way of Diſtinction, Bogs, or boggy Lands: the others lie in a Flat, and often extend upon an exact Level for a vaſt many Miles. Theſe are called Fens and fenny Lands. Such as thoſe in the Iſle of Ely, Lincolnshire, and elſewhere.

This is the general Diſtinction eſtabliſh'd by Cuſtom; and thus we are uſed to call them, though if the Word Bogs and boggy mean only wet and ſoft, as many uſe them, they are as applicable to many Parts of the Fens, as to the hilly Quagmires, many of theſe Fens being as tender and ſoft, and ſhaking under the Foot as much to the full as what are more particularly called Bogs upon the Hills, or between them.

There is ſome Difference in the Ways of draining theſe variouſly ſituated wet Lands, and to this is owing the Difference of their Denomination. In this Diſtinction the boggy Lands have an Advantage over the fenny, in that they have a greater Deſcent to drain them; and thence principally ariſes the Difference in the Methods of proceeding: on the contrary, the fenny Lands have this other Advantage, that in general they are leſs wet, and leſs rotten, than thoſe Bogs eſpecially which lie between Hills.

To underſtand upon what Foundation the Draining of theſe Lands is eſtabliſh'd, it will be neceſſary to know from what the Miſchief ariſes: or how they become ſo wet and ſoft within, that they are render'd unfit for all the Uſes of Agriculture.

Bogs are made by Springs, which riſe at ſome Depth under the Surface in thoſe Places. Hills naturally give riſe to Springs, and when theſe iſſuing from ſome Depth, meet with a Weight of Earth that pens them in, they ſpread under the Surface where the Soil is ſoft, and they moiſten and rot it, till it becomes a Quagmire underneath, cover'd only by a Turf at the Top, which ſinks as it is trod upon, riſing in ſome other Place, and is continually in a trembling Motion.

Fen Lands on the contrary, lie on Flats, are nearly upon the Level with the Water of Rivers that run near them, and are ſubject to be overflowed by the Swelling of thoſe Rivers. When this happens, they lie ſo flat that the Water cannot get off; and hence ariſes the Neceſſity of draining them. There are ſome Fen Lands that are conſtantly and continually wet, not accidentally from thoſe Overflowings. Theſe approach more to the Nature of the Bogs; and the Method of draining them is to be accordingly contrived, partly from that for Bogs, and partly from the other.

CHAP. VI.

Of draining boggy Lands.

THE firſt Thing to be done where a Piece of boggy Ground is to be drain'd, is to examine it well in order to find the loweſt Part; and to obſerve what Deſcent there is. When this is found, a Drain is to be open'd, and it muſt be cut through the Ground to ſuch a Depth, that its Bottom be at leaſt a Foot below the Level of the Springs. When this is done, the Water from the whole adjacent Ground naturally drains into the Cut; and there, provided a free Paſſage be kept open, it runs off.

From what has been ſaid before of the Nature of the boggy Land, it is plain that this ſingle Operation, provided it be judiciouſly deſign'd, and properly perform'd, muſt effect a Cure. We have ſeen the Cauſe of this Boggyneſs is, that the Water of certain Springs is damm'd up, or pent in by Earth; a Paſſage is here given, and conſequently the very Cauſe of the Evil is removed. The Water that ſwelled and ſoaked the Ground, becauſe it could not get off, has now a Paſſage by which it runs away freely and continually; and the Ground which was made a Quagmire by its being before pent in, becomes dry enough to be uſeful.

The great Caution to be obſerv'd in this Particular is, that the Drain be cut deep enough: for if it be not deeper than the Bottom of the Springs, the Remedy will be imperfect. There will ſtill be a Lodgment of Water at the Bottom of the Bog, the Drain carrying off only what is above the Level of its Bottom; and it is ſurprizing to ſee how much Miſchief a little Wet at the Bottom of a Land, that has been us'd to be boggy, will do.

The Depth is ſo uncertain, there is no giving any general Rule for it: but ſome gueſs may be made from the Nature of the Ground, and its Situation. The Way appears greater to the Spring than it naturally is, becauſe the boggy Land is raiſed and ſwelled up beyond its proper Surface, by the Force of the Water that is confin'd in it; inſomuch that in a Bog well drain'd, it will often ſink two, three, or four Foot from what was the Height while wet.

The Depth at which the Springs lie, is always greater according to the Weight of Earth that pens them in: but he who ſets about this with Diſcretion and Judgment, will know whereabouts it will fall, from his Obſervations; and he muſt have Reſolution to go through what he has undertaken, for all will be ſure Profit in the End.

The Drain muſt be begun in the loweſt Place, and carried into the Bog towards the Spring Head; and Trenches are then to be cut acroſs, at proper Diſtances; by Means of which every Part of it will be drain'd thoroughly, and perfectly.

The Breadth of the Drain muſt be proportioned to the Depth; and this the judicious Undertaker will eaſily contrive, for, by the beforenamed Obſervations, he will be able to gueſs very nearly at the neceſſary Depth of the Drain, before he begins the Work.

Some farther Cautions are neceſſary to be given in this general Account of draining Bogs, for the ſecuring and keeping the Advantage perpetual, and avoiding Inconveniences.

When ſmall and ſhallow Drains are ſufficient, as is often the Caſe, particularly in ſome of the ruſhy Bogs, they may be left open; and no farther Care is neceſſary than to look at them now and then, to ſee they are kept from filling up. But when they are broader and deeper, ſome Precaution is neceſſary to prevent Accidents.

As has been directed in the cutting of Ditches, by Way of Fence, the Earth that is thrown out muſt never be left upon the Edges of theſe ſmall and ſhallow Drains, as is too frequent a Practice. If it will ſerve to neither of the Purpoſes there mentioned, of Firing or Manure, it muſt be carried off, to be thrown away; but generally it is a Kind of turfy Matter, and will make a coarſe Sort of Fuel.

When the Drain is wide and deep, as there is no Neceſſity for keeping it open at Top, 'tis beſt to cover it up to prevent Cattle tumbling in. In this Caſe a good Quantity of rough Stones muſt be thrown in: they ſhould be ſuch as are hard, and will not ſettle too cloſe, but leave a free Paſſage for the Water among them. Upon theſe is to be laid refuſe Wood, and over that ſome of the Earth that was thrown out in digging. By this Means a thorough Paſſage will be left free for all the Water the Springs yield, and there will be none of theſe frightful Openings upon the Surface. Care muſt be taken to keep the Trenches clean; and then this main Drain will keep in order for Ages, and preſerve the recovered Land from growing wet again.

This is the common Practice in the draining of boggy Lands, explained in all its Branches, and ſhewn to be founded upon a real Knowledge in the Cauſe of the Dampneſs of ſuch Lands; but it is not our Intention to leave the practical Huſbandman, with only the common and general Rules to guide him. Experience has ſhewn, that the beſt general Methods admit of Improvement in particular Inſtances; and we ſhall ſhew him how he may take a different Courſe from the common, in ſome Caſes to a greater Advantage.

Though in many Places the Trenches running to the main Drain, will keep clean and open of themſelves, if the Earth thrown up out of them be removed; yet in ſome Bogs the Earth naturally ſwells in ſuch a Manner, that they will fill up of themſelves, though cut to a conſiderable Depth, from their Bottoms riſing, and their Sides puſhing towards one another.

I have ſeen in Lancashire ſuch ſtrong Inſtances of this, that one might trace the old Trenches over the Surface of the Bog, not in Hollows, but in a Kind of rough Seams, as it were, rais'd up above the Reſt of the Surface; as the Letters and Figures carv'd in the famous Grotto of Antiparos, not only fill up in Time, by the ſwelling of the Stone, but project beyond the Level.

In theſe Caſes the Bog always remains a Bog ſtill. The Expence has been thrown away, and the Attempt of draining given over: if ſuch diſcouraging Circumſtances ſhould croſs our Undertaker, 'tis fit he ſhould know how to guard againſt them: for that is to be done, and there is no Need of giving up the Deſign.

In this Caſe he is to treat his Trenches in ſome Degree as he does his wide and deep Drain, keeping them from filling up of themſelves, by throwing in ſomething between that will preſerve an Opening for the Water, and yet keep the Sides aſunder.

The beſt Method of doing this is as follows. In the firſt Place, let the Trenches be cut ſomewhat deeper than otherwiſe they would need to be, ſuppoſe, for Inſtance, three Foot deep, and two Foot over. Then, as ſoon as they are made, let the Bottoms of them be cover'd with freſh cut black Thorn Buſhes: upon theſe let him throw in a Quantity of large refuſe Stones: over theſe let there be another Covering of black Thorn Buſhes, then a Covering of Straw; and upon this ſome of the Earth, ſo as to make the Surface level with the reſt. Theſe Trenches will always keep open, and their Advantages will be found in every Inch of the Land.

In this we are only bringing the Experience of one Part of the Kingdom to the Aſſiſtance of the others: we are only laying before the Huſbandman of Lancashire, the Practice of the Drainer in Oxfordshire, for this is a well known thing there, and has been continued from Father to Son theſe many Generations.

Nothing is more eaſy nor more familiar to Reaſon; nor is there any boggy Piece of Land where the large Drain can be made effectually, that will not be perfectly cur'd by this Practice. Yet ſo little ready are the Huſbandmen, in general, to make uſe of their Reaſon againſt croſs Accidents, or to enquire into the Practice of others, that, at this Hour, many Pieces of boggy Ground may be ſeen in the County before-cited, with the Trenches all grown up, as juſt mentioned, and with a deep dirty Drain half full of Rubbiſh, which might every one have been thoroughly and perfectly cur'd, by this ſingle and ſlight Expedient. So eaſy is it to throw away Money to no Purpoſe upon the moſt rational Deſign; and to give up what is practicable.

In Staffordshire, inſtead of black Thorn Buſhes, they make the firſt Lay of a Quantity of freſh Heath, and then put the Stones, covering them with a good Coat of more Heath, and then with Earth. This is a better Method where Heath is to be had; and that it commonly is in the Neighbourhood of Bogs, for it is tougher and more durable in the Wet than the other; and at the ſame Time, though it lies cloſer a great deal, yet there is ſomething ſo ſtubbed in the large Shoots, that they will not be preſs'd entirely flat.

It is certain, that the worſt boggy Lands that lie upon or between Hills, may be drain'd by this ſingle Method: which is eaſy, cheap, and not liable to failure by Accidents, if properly conducted: and it is equally certain, that the Value of the recover'd Lands is very great, for they become fit for a Variety of Purpoſes, as ſhall be ſhewn hereafter.

Let not their Appearance, while in a Bog, diſhearten the Undertaker; for their Produce, when reduced by draining, to firm Land, will be altogether different from that which naturally grows upon them while wet; and this Improvement may alſo be promoted by Art: but before we ſpeak of that, it may not be improper to give one farther Method of making the neceſſary Drains, in ſuch boggy Ground as is ſoft and mellow, and but moderately wet.

For this Purpoſe ſeveral Holes are to be dug in a ſtrait Line along the Bog, at about eight Foot Diſtance; theſe are to be about ſeven Foot deep, and four Foot wide. A Man is to get into one of theſe as ſoon as it is dug, and to work away toward the next, each Way, leaving a Coat of Earth of about three Foot thick at the Top. Thus he is to proceed in each Hole, till, by this Means, the ſeveral Burrows meet, and there is a ſubterranean Drain made through the whole Bog.

Bruſh-wood, or any uſeleſs Materials of a like Kind, are to be thruſt into the Drain everywhere, to keep it open, and thus the Water will be carry'd off with great Certainty, and the Bog will be left dry and firm Land. This Method was firſt invented near WEEFORD in STAFFORDSHIRE, and is at this Time practiſed in many of the neighbouring Places with a laſting Succeſs.

When a Piece of Ground is thus recover'd from its boggy State, it will ſtill be found unfruitful. Its natural Product in this wet Condition was Moſs, and it will continue to yield Nouriſhment to that, and, till aſſiſted by Art, to little elſe, becauſe all its Juices will be exhauſted by that uſeleſs Production. To cure this Fault, it is to be dreſs'd with Aſhes, kept dry, as before directed, in the Chapter on that Subject, in our Second Book. Theſe are to be ſpread over it, at the Rate of thirty Buſhels to an Acre; and they will act very effectually, in deſtroying the Moſs, and in enriching the Soil for better Products.

CHAP. VII.

Of the Draining of Fenny Lands.

IN treating of Fen Lands we are to diſtinguiſh, as before hinted, ſuch as are naturally wet at the Bottom; and ſuch as become wet by the Overflowings of Rivers, from Land Floods, or other Accidents; for a different Method is to be taken in theſe diſtinct Caſes. In one, nothing is to be done but the carrying off a Quantity of Water that has fallen upon them by Chance, and ſtagnates there, becauſe of this flat and level Situation: in the other, or thoſe naturally and continually wet, all is to be done that is requiſite in the draining of Bogs, of which they are a Kind; and often the moſt difficult of all to drain, becauſe of their flat Situation.

As to thoſe Fen Lands which are only overflowed at Times, and have a good Soil, if the Water could be carried off at Pleaſure it would be an Advantage, and not a Detriment, provided it fell on at proper Times; for it would only anſwer that uſeful Practice, the drowning of Meadows. The Soil of theſe Fens is, indeed, generally good: but the Water does not always come on ſo regularly as it might be wiſh'd, nor is it to be got away without Labour and Expence: a great Part of it uſually remaining till the Sun and Wind carry it off. This is much too long for it to lie profitably on the Land, and hence ariſes that Injury which ſuch Fen Lands ſuffer, and the Advantage of draining them.

If the Water can be compleatly carry'd off from the Surface of theſe, 'tis all that is requir'd; but in the other Caſe, were the upper Part of the Soil ever ſo well drain'd, the Source of the Wet being within its own Bowels, the Miſchief would return, unleſs that had a Way made for it; which can only be done upon the true Principles of draining, as laid down in the former Chapter: the finding the Deſcent, and cutting Trenches to a proper Depth. In general alſo this is the beſt Way with thoſe which are only ſubject to occaſional Overflowings; for when theſe have happened often, and the Water has been uſed to lie a great while upon them, they are ſoak'd down to a great Depth, and have acquired, by Habit of Wetneſs, much the ſame Qualities with the naturally boggy Grounds. Indeed, the carrying off the Water lodg'd on them, by Land Floods or heavy Rains, is only a ſuperficial and partial Cure: the draining them to the Depth, though it may be a more expenſive, is a much more perfect Remedy: nor is the other ever to be done perfectly, by all the Contrivances that have been made. The beſt they do is to get off a great deal of the Water, and leave the leſs for the Sun to dry up; for they never drain them entirely.

The judicious Undertaker will, to each Kind of Land, if it be of any Extent, uſe both theſe Methods; for by firſt throwing off the ſuperficial Water, he will be able to carry on his Works for a deep and thorough Draining, with much greater Eaſe and Succeſs.

This ſuperficial Water may be carry'd off by Engines, when in very great Quantities, with little Expence: the Sight therefore of a Sea upon the Fen, at certain Seaſons, need not diſcourage the Undertaker from his Attempt. I have ſeen many Fen Lands of great Extent, that have been a perfect Lake to Appearance for ſome Time while overflowed; but, by Degrees, a good Part of this has run off, and the Remainder, which has lain and render'd the Ground uſeleſs, might have been carry'd away by the moſt common Engines. But the Negligence in this Caſe is ſurprizing. We propoſe here to inform the Farmer how he may make an effectual Cure; not only preventing the Effects of his Neighbour's Neglect, but rendering the Land ſafe for ever, from either its own Wettneſs, or ſuch Accidents.

This compleat Remedy and Preſervation is to be effected by three Things, ſuppoſing the Land both wet in itſelf, and liable to Overflowings.

Theſe are, firſt, the taking off the Water lodg'd on the Land, at preſent, by Floods; ſecondly, the draining it of what riſes from its own Bottom; and, thirdly, the preventing its being overflowed from the Land Floods and Rains for the future.

For the firſt Purpoſe, or carrying off the Water that has been brought on and left there, by Land Floods, many Engines have been contrived, and are, at this Time, uſed in different Places; but none anſwers better than the Sail Wheel, which they call, by way of Eminence, in the Iſle of Ely, the Engine. This is compoſed of about a dozen Spokes, faſhion'd according to the particular Purpoſe, and is turn'd by Sails like thoſe of a common Windmill.

This Engine will carry Water excellently either off a Flat or where there is ſome Riſe; but for this different Uſe there is to be ſome Variation in the Make of it. When 'tis only to puſh the Wet along a Flat, for the getting it off, the Spokes are made broad, and ſet a little ſloping. And 'tis amazing how vaſt a Quantity of Water it will thus throw off in a Day's Time, the Spokes all moving between a couple of upright Boards, which make a kind of Trench for them to play through.

When the Water is to be rais'd to any little Height, in order to be carried off, the Spokes are made hollow like ſo many Scoops; and they are ſet ſo as to deliver the Water juſt at that Pitch, which they do inceſſantly, and with great Regularity.

Laſtly, if the Water be to be thrown out at a larger Height, as over a Bank, or an Eminence of the Ground; the Spokes are for this Purpoſe, made in the Faſhion of ſo many Boxes, which do not throw the Water out before them, but take it up, and retain it; letting it, as they riſe, run into an hollow Circle that goes round the Spokes, at about half their Length, whence it is diſcharg'd again from the Back of the Spokes as the Wheel deſcends.

Thus is this Engine ſuited to all the common Purpoſes of Draining: and kept up in Repair at a ſmall Expence: ſo that the Farmer is right to prefer it to many of the more complicated Machines that have been propos'd, with Promiſe of Miracles from their Inventor, but with much leſs real Advantage than is every Day found from this plain and common Wheel.

When the Water of the Land Floods is thus carry'd off, the Undertaker is to ſet about to remove that which riſes in the Land from its own Bottom. This he will do with Eaſe enough, now that the accidental Load is taken away; whereas, otherwiſe, there would have been endleſs Interruption of his Works, and Miſtakes about the Springs.

He is now to act exactly upon the ſame Principle as in draining of the Bog, only as the Compaſs of Ground in the fenny Lands is often greater, the Works of every Kind muſt generally be larger.

A main Drain is firſt to be cut; and this muſt be done with the utmoſt Care and Contrivance, for upon this the Succeſs of the Undertaking depends. The Situation of the whole Land to be drained, muſt be conſider'd for this Purpoſe. And this main Drain muſt then be cut deep enough to carry off the Water from the whole Level, at the Depth from whence it is found to ariſe: This is often not more than a Foot or two below the Surface in the loweſt Places.

The Breadth of this Drain muſt be proportion'd to its Width; nor need the Undertaker be under any Concern on this Head: for ſuppoſing all to be abſolute Refuſe that is thrown out, the Benefit ariſing to the Land will very well pay the Expence: but often it is of Uſe, as has been obſerved already.

The Depth and With of this main Drain being determin'd, its Courſe is the next Thing to be conſider'd. And for this little Advice will be ſufficient, for it is to be carried from the loweſt Part, as its Bottom, to the neceſſary Part of the Ground.

As to its Form, it muſt be wideſt at the Mouth, or Opening, and muſt grow narrower all the Way to its Head.

If the Compaſs, or the Situation, or other Circumſtances of the Ground require it, there may be more of theſe main Drains: and there muſt be ſo, where it is plain, as often appears at Sight, that one cannot anſwer the Purpoſe. In this Caſe they are all to be made exactly as the ſingle one already deſcribed; to be carried in a ſtrait Courſe; to be of a ſufficient Depth; and to be wideſt at their Mouths, and narroweſt at the Head.

When the main or middle Drain is finiſh'd, it will be needful to open a great Number of other leſſer Drains; though, in theſe large Works, they are generally too big to be called by the Name of Trenches. Theſe muſt be cut upon the ſame Principle with the great one, narroweſt at the Head, and wideſt at the Mouth; and of a proportioned Depth.

Theſe ſmaller Drains are to be brought from every Part of the Work; and to be carried ſtrait into the great Drain, at the neareſt Parts.

All being thus prepared, the Effect will immediately follow, and will be ſuch as is not to be conceived by thoſe who have not been accuſtomed to theſe Undertakings. The Ground which has been left ſoft and pappy, from the Water juſt carry'd off; and which is ſhaking at every Step in the lower Places, from its own natural Wetneſs, will, by the continual running off of the Water, become dry and ſolid. It will ſink a Foot or more throughout, if it have been naturally very boggy; and it will remain faſt under the Feet without ſhaking, and bear Carriages. I have ſeen Lands, on which a Horſe's Foot would break through the Turf, and he would be let in up to the Belly, become hard enough for a Waggon in a little Time by this Method: and ſuch as would ſwell and riſe, and dance under a Man's Foot like weak Ice, bear a Coach over them without Motion; in ſhort, by Degrees, the wetteſt and boggieſt fen Land will thus be brought to a Conſiſtence for every Sort of Culture.

When this good Effect has been obtained from the Drains, the Undertaker's Care is not to ſtop: for though, with proper Caution, the Ground thus recover'd will keep good for ever; yet, with Neglect, it will ſoon relapſe into exactly its old Condition.

To

To prevent this, in the firſt Place, Care muſt be taken to keep the Drains clear, and of their due Extent and Depth at all Times. Twice a Year, that is, in the Beginning of OCTOBER, and about the End of APRIL, they muſt be thoroughly cleanſed from Weeds, Mud, and other Foulneſſes, that gather very faſt in them, and when they are neglected, ſoon choak them up, and return all into the old Condition.

But beſide this, Care is to be taken alſo, to prevent the Miſchief of Floods, acting upon the Land as formerly. 'Tis true that the Water brought on by thoſe, could not remain upon the Ground as it uſed to do, becauſe of the Service of theſe Drains, but then it would in running off, tear and deſtroy all the Works; and beſide the immediate Miſchief it would always occaſion, would entail an endleſs Expence upon the Undertaker.

To guard againſt this, let him examine well in what Place, and from what Source theſe Waters came on. If the Inundation happen from the Overflowing of a River, the Buſineſs is to bank in that River in a proper Place, leaving it ample Scope for its Courſe, but juſt keeping it off the Ground. If it happen immediately from the high Lands, Care is to be taken to give it a Vent into the next River, to prevent its falling upon the Lands: this Work will require in ſome Places more, and in ſome leſs Expence. In ſome Situations it is impracticable, and then the Drains muſt be truſted to: but where it can be done within any moderate Price, it is always worth while; for the Recovery of ſo much Land under a Certainty of its continuing good for ever, is an Article of prodigious Importance.

Different Fen Lands lie under different Degrees of the Inconvenience of being drown'd, and in ſome the Remedy is eaſy, in others more difficult, in ſome utterly impracticable, within ſuch an Expence as the Advantage would repay. Where all the Sources of Boggyneſs and Wetneſs concur, the Methods already deſcrib'd are all to be uſed; where only a Part, there Part of the Remedies is ſufficient. We have in this Conſideration taken it at the very worſt; and the Undertaker ſees all he can have to do in order to carry off the accidental Load of Water, to drain away the in-bred Quantity, and to keep the Land dry, that he has thus recovered from its uſeleſs State: he is happier where leſs of the Sources of the Miſchief concur, that he may reap all the Advantages at leſs Expence.

CHAP. VIII.

Of draining flat Lands near great Rivers.

THE Borders of large Rivers near where they run into the Sea, afford often a peculiar Kind of Lands that require draining. Theſe lie within the Reach of Tides, which riſe high in ſuch Places, and being alſo liable to the Effects of Land Floods, no Grounds whatſoever are ſubject to receive ſo large a Quantity of Water: but then none are ſo eaſily freed from it, or at ſo ſmall Expence.

Numb. X.

Theſe Lands lie above the low Water Mark, and below the high Water Mark; there are many of them along the Side of the THAMES, where at one Time they were waſte and neglected, but at preſent are drain'd, and are very valuable. All large Rivers where the Tides run high, are border'd in many Places with ſuch Grounds: and beſide the Tide at its Times, they uſually receive Land Floods, and give them into the River by a Creek.

Theſe Lands have by ſome been confounded with Salt Marſhes (of which we ſhall ſpeak hereafter) but very improperly: they have great Advantages over them, in that they afford freſh Water which the Marſhes naturally want; and Shelter for the Cattle, in which they are uſually as deficient. They have often all the Requiſites for being excellent Land, and only ſtand in Need of being drain'd and defended from freſh Overflowings.

Whoſoever ſhall have ſuch a Piece of Land in his Hands, and has the Prudence to intend rendering it ſerviceable, is freed from the Labour and Expence of Drains, for the Creek form'd by the freſh Waters for themſelves, anſwers that Purpoſe. He is only to manage the Outlet of this rightly, and to defend it by a Bank.

The firſt Work to be undertaken is, the Bank: this is to be carried all along the Edge of the Land to the River, only leaving the Opening of the Creek for the preſent; for ſhould that be block'd up, the Land would be drown'd by the freſh Waters, which would have no Paſſage: and yet if it were left thus entirely open, the Tide forcing itſelf up at its Riſe, would overflow the Lands as uſual, and burrow its Channel deeper.

Therefore when the Bank is all made, and firm, the Creek is to be ſtop'd up at once by a Number of ſtout Workmen, with good Materials, who are to make a very thick and ſtrong Head to it, only laying in three or four long Troughs of Wood, which are to reach quite through the Head into the freſh Water of the Creek, and to open into the River. Theſe Troughs are to be made each of four rough Planks, and are to be open at the End next the Creek; but at the End that comes to the River, they are to have each a Door that flaps to, when the River Water bears upon them, but that opening out-wards gives Way freely to the Land Flood.

When theſe Troughs are laid in, the Bank is to be carried on over this Head, and all is done. The Doors, opening out-ward, give Way to the Water of the Creek, which runs out freely all the Time the Tide is down; and when that riſes, inſtead of forcing in, it only ſhuts the Doors of the Troughs. So that the whole Inconvenience is, that none of the freſh Water can run out, while the Tide is at this Height; but the Troughs being proportion'd properly, the Diſcharge during the Hours of low Water is ſufficient. As the Doors of the Troughs keep out the Water there, the Banks keep it out from the Edge of the Field; and the whole is at once ſecur'd from Inundation.

This is an Undertaking in general the more profitable, in that the Lands thus recover'd, are

for the moſt Part of the beſt Kind we know for Paſturage. There is ſome Expence in the making of the Bank, but it is eaſily kept up, and the Troughs, if made of proper and firm Stuff, will laſt a great while without Repair.

CHAP. IX.

Of the ordering of Salt Marſhes.

'TIS a great Quantity of Land in this Kingdom that comes under the Denomination of Salt Marſhes, and this is with Reaſon ſeparated from all other Land, being in its Nature, Qualities, and Products different from all beſide. The Sea Water is to be kept off from this, and that often at a conſiderable Expence; but this is not all that is required for the rendering it uſeful according to its intrinſick Worth. For this Reaſon it were idle in this Chapter to treat only of the Means of keeping it dry: the whole Method of managing or ordering it ſhall be laid down.

A great deal of the Salt Marſh Land in England, is at preſent turn'd to a very good Account. But the greater Part even of that might be made to yield a much larger Profit, and ſome that is utterly neglected, becauſe Improvements of it are ſuppoſed impracticable, might be render'd of great Value to the Owner. We ſhall therefore begin from the Source here. We ſhall enquire into the different Conditions of Sea Marſh Land, and lay down not only the common Methods which are every where practis'd with Advantage, but make publick ſuch as are peculiar to certain Places, tho' they may be uſeful in all; and finally add, what Reaſon ſhews may be done farther with Profit.

In the firſt Place, what we underſtand by Salt Marſh Land, is a Land that lies low and flat, and is within the Reach of the Sea, or Salt Water, at the Mouth of great Rivers. Hence it is liable to be overflow'd by the Salt Water, and the Ditches are full of the ſame at all Seaſons of the Year.

Now we may eaſily ſee, that though this Land be ever ſo good in itſelf, as the moſt part of it is very rich, yet from this Condition of being continually liable to Overflowings of Salt Water, it will be ſoaked too much: it will yield or keep no freſh Water for the Uſe of Cattle: no Trees or Shrubs will grow well upon it; ſo that there will want Shelter: and its Produce, whatſoever, will be liable to be cut off by the nipping Winds of the Spring, becauſe it is expos'd to them, and to the Sea Breezes which are yet more deſtructive than they.

By this Account we ſee how many Diſadvantages this Land lies under, beſides thoſe of that before mention'd: but ſtill its natural Richneſs makes it worth taking Care off. The Work muſt be more, and the Expence greater than that which is needful on the other, but then it will anſwer very well by its Fertility.

The two great Inconveniences attending Salt Marſh Land, are theſe, the Overflowings of the Salt Water, and the Want of freſh. Theſe may be provided againſt, and when this is done, if we add Shelter for the Cattle that are to be fed there, as well as the Crop they are to be fed upon; we ſhall bring them to be equal or ſuperior to any Paſture Lands whatſoever: and this is to be done with Certainty.

For the firſt Thing, let the Undertaker of theſe Lands, when he has conſider'd the Source of their Misfortune, the Abundance of Salt Water thrown on them; examine their different Condition; in what Degree they are liable to it; what Quantity of building or banking will be needful to keep it out; and in what Reſpect they are as to Shelter and Trees.

When this has been thoroughly conſider'd, let him ſet to work, remembering that he has three great Articles to accompliſh, namely, the keeping off the Salt Water, the getting a Supply of freſh; and the giving that Shelter which Nature has denied.

The Sea or River Tides are to be kept out by Banks or Walls. When 'tis only the Water of a River to which they lie expos'd, banking will do, but then it muſt be at a very great Expence: where 'tis the main Sea that beats upon them, Walls are the beſt Security, and theſe muſt be made of a vaſt Thickneſs to reſiſt the Force and Weight of the Water; and of a great Height to defend the Lands from the higheſt Tides.

When Banks are uſed, they are to be cautiouſly made in Form as well as Subſtance, and no Expence is to be ſpared in the giving them a due Body and Height; for if there be, all that is beſtow'd is often thrown away. To come to Particulars: when the main Sea is to be fenced out from a good Compaſs of flat Salt Marſh Land, let the Undertaker lay the Foundation of his Bank fifty Foot broad, and carry it ſloping and tapering all the Way to the Top. The Height muſt be ten or twelve Foot, and the Thickneſs at the Top about three Foot. It is to be raiſed of ſound Earth well laid together; and the Slope is to be principally on the Face next the Sea. This Part muſt alſo be cover'd evenly with Turf, like a Bank in a Garden; that the Waves may roll eaſily againſt it; not bearing againſt a Perpendicular with all their Weight and Force, nor meeting with any Thing to ſtop, interrupt, or ruffle them in their Courſe.

Let any one obſerve the waſhing of the Sea Water upon ſuch a Slope, and upon a common Shore, which is rough as Nature leaves it, and he will ſoon ſee the Reaſon of this Advice. The Waves have fifty Times the Force againſt the Ground where they are ſtopt, and broken, that they have when they roll up evenly and ſmoothly.

While the Face of this Slope is entire, they always run up in that Manner, and the Bank is ſecure; but whenever there is the ſlighteſt Breach in the Turf, the Waves tear and enlarge it in a ſurprizing Manner. This may inſtruct the Owner to have the Bottom of the Banks carefully look'd to from time to time, that the Turf is kept ſound. A ſmall Expence will anſwer this, for 'tis only two or three Feet at the Bottom that is liable to Miſchief, the Tides riſing but ſo high againſt a ten Foot

Bank

Bank in their common Courſe; the reſt of the Height being made for preſerving againſt thoſe extraordinary Tides, which happen once in a Year or two, or at greater Diſtances of Time.

Where Stone is to be had conveniently, Walls are an excellent Fence againſt theſe Seas. Their Proportion muſt be nearly the ſame with that of the Banks; and they anſwer to the additional Expence by being very durable.

The Name of a fifty Foot Bank may fright one who is not accuſtom'd to this Kind of Work, but it does not come to ſo much as might at firſt Sight be imagin'd. 'Tis of this Thickneſs only at the Foundation, and 'tis to be made, at the common Price of Labour, for an Expence that a few Years of the Profit by the Land repays.

'Tis here ſet at the higheſt: where the Sea has leſs Power, a ſmaller Expence will ſerve, but at the moſt that can be needful, 'tis perfectly worth the Charge.

When the Land is thus defended from the Overflowings of the Salt Water, it will be found in a Condition to bear excellent Paſturage; and the next Conſideration is to find freſh Water. For this Purpoſe let the Undertaker look out for a convenient Part of the Land, and there ſink a large Pond. Let this be well lin'd at the Bottom and Sides with a tough Clay, and left to receive the Rains. It will hold theſe, and ſupply a large Number of Cattle.

When the Recovery of this Salt Marſh Land is carried thus far, the next Deficience is to be conſider'd; that is, the Want of Fences: whether theſe are wanted in the common and literal Senſe of the Term, of ſeparating one Piece of Land from another, or not, they are ſure to be needed doubly here, to what they are on any other Lands, in the farther Occaſion of ſheltering the Cattle, and defending the Graſs from the Winds.

We have ſeen the Land from a Salt Water Marſh, reduced to be dry, and to bear good Paſturage, and we have ſupplied it with freſh Water: but we ſhall find the Cattle miſerable for want of Shelter, and the Graſs will often be ſeen cut off at the Tops in Spring by the Sea Breezes, as if it had been mow'd. To prevent this, the firſt Attempt is to be by Plantations of Trees and Hedges. Ditches alone will ſerve for Fences, and the Separation of Grounds in thoſe Places, but theſe are wanted for the other Purpoſes.

If one Kind of Tree or Shrub will not thrive upon the Ground, let the Undertaker try another, and ſo on till he has gone the Round of all that can be uſeful. It muſt be confeſs'd, there are ſome Salt Marſhes on which none of the common Trees will thrive; but even here there are uncommon ones to be called in. The late Lord PETRE, of THORNDON in ESSEX, gave Slips of a particular Shrub, called the Sallow Thorn, or Sea Buckthorn, to an Owner of ſome Marſh Land, whereon no other Hedge would grow, and it ſucceeds to this Day very well. This is not the Shrub one would chuſe preferably to others for a Hedge; but where others will not thrive, 'tis valuable.

The Native Place of this Sea Buckthorn, as its Name expreſſes, is by the Sea, ſo that no Wonder it does in theſe Places. 'Tis raiſed for its Beauty in moſt of the Nurſery Gardens, and to be had cheap enough; ſo that a Fence is eaſily rais'd with it. When other Things have fail'd, Prudence recommends the Trial of this; and though not at this Time commonly known, he will be of real Service to his Country, who contributes to make it ſo; and to ſhew by Example, the Truth of what we have propoſed.

If this Shrub cannot be had; or if the Place be ſuch that this will not grow, it will not be neceſſary altogether to give up the Trial. Shelter is as needful as even the keeping the Ground dry, and other Means muſt be attempted.

The Undertaker is by this Time acquainted with the Nature of banking. He has had it done in great Strength, and conſequently at a large Expence on the Edges of his Land; let him order it to be repeated in a ſlighter Manner, and at a ſmaller Expence in the Middle.

A Bank will at any Time anſwer the Purpoſe of Shelter and Defence, both to the Crop and the Cattle, as well as a Hedge; though it does not anſwer all its other Purpoſes.

It will be convenient for this Uſe to raiſe a Couple of Banks in ſtrait Lines along and acroſs the Land, or in any other Direction where the Courſe of the Breezes renders ſuch a Variation neceſſary. Theſe may be ſix Foot high, and juſt of a Thickneſs to ſecure them from Accidents. They will break the Force of the hurtful Winds, themſelves; but that is not all their Uſe, for they may be planted with Trees and Shrubs, which will grow upon them, though they would not upon the Flat; and thus all the neceſſary Uſes of Defence and Shelter will be anſwer'd.

Proper Care muſt be taken, that the Trees and Shrubs ſet on them are ſuch as will ſtand the Sea Breezes beſt; and thus there will be the Ground Work of a fine Plantation, uſeful and profitable for many Purpoſes, and on many Occaſions; in the ſame Act that gives the Cattle and the Crop their firſt Shelter.

In this ſmall Compaſs lies all that is needful to be done in the Ordering of Salt Marſh Land; and by theſe Means may all the Salt Marſh Land at this Time taken in thro' the Kingdom, be render'd of double Value to the Owner; and great Quantities that yet lie neglected, may on the ſame Principles be attempted with a Certainty of Succeſs. This will be adding even to the Extent of our Iſland. No Lands are ſo perfectly added to it as thoſe gain'd from the Sea; and there are in many Parts of the Kingdom great Tracts, which there requires only Spirit and Reſolution to turn to a large Account, and make to ſerve as an everlaſting Poſſeſſion to their Families who recover them. This may be ſaid with the greateſt Truth, that upon a careful Examination of the ſeveral Lands of this Kind, that have been, and that might be added to our Iſland, a great deal is recover'd from the Sea, which lay much more deſperate, than many Thouſands of Acres that are at this Time utterly neglected.

Let him who has Spirit for ſuch an Undertaking conſider this. Let him obſerve the Situation of the recover'd Salt Marſhes, and the waſte overflowed Land of the ſame Kind, and he will

ſee

ſee beyond a Diſpute or Doubt, that more Expence has been beſtow'd upon the former, than is or can be needful on the latter. He will find that thoſe Lands ſo recover'd at a greater Expence, have repaid it long ſince; and continue, and will continue for ever a very valuable Poſſeſſion: what can therefore be ſo plain, as that theſe others muſt be worth the employing that leſſer Price upon.

The Salt Marſh Land when thus recover'd and preſerv'd in its uſeful State, exceeds all others whatſoever for Paſturage. It fattens Cattle ſooner than any; and they are ſafe from the Rot, and many other deſtructive Diſorders common in other Paſtures, while they feed on it.

One Improvement there is of theſe Lands, which though practis'd in ſome Places, is far from being univerſal, though founded on the Principles of Reaſon and Knowledge. This is the letting in the Sea Water upon them at proper Times, and in due Quantity.

The Advantages of drowning Meadow Lands with freſh Water, are ſufficiently known: this anſwers that Purpoſe, but not that only. We have ſeen already, that Salt is an excellent Manure in ſmall Quantities, though it be deſtructive to all Vegetables of the Earth in too great Abundance. Why ſhould we not therefore allow it in moderate Quantity to theſe Lands, when we have it ſo eaſily, and ſo happily in our Power, by the giving them a proper ſoaking of Sea Water.

We know they owe their particular Advantages over all other Paſture Grounds, to the Effects of the Salt Water, why then will we not give it them in a due Proportion, after we have banked it out in thoſe over Quantities, in which it deſtroy'd the Land. 'Tis very certain, that in a due Proportion Sea Water will add to the Fertility of theſe Lands; and it is eaſy in the Ordering of their Banks and Fences, to provide for the letting it in at a proper Seaſon, and in due Quantities. This I would have every one who is concern'd in Salt Marſhes conſider, and he needs not doubt but he will by a prudent and careful Obſervance of it, improve his Grounds above all thoſe of his Neighbours.

'Tis upon the Sea Coaſt that the largeſt Advantages are to be made by taking in Land for theſe Purpoſes; and this is practicable with the greateſt Certainty, and at the ſmalleſt Expence. Where the Owze is firm, and bears a tolerable Shew of Graſs when the Tide is out, here the Expence is eaſier, and the Succeſs more certain.

They have in many Places taken in the Owze where 'tis ſoft, and cover'd at low Water with Sea Weeds. This will come dearer, and be ſubject to more Diſadvantages: it is therefore certain and plain, that the other may be done more to the Profit of the Undertaker, in Places where Nature favours the Attempt.

When any one ſhall determine upon this Work of recovering new Land from the Sea, he is to conſider the Nature and Subſtance of the Owze, according to the Characters juſt given of Firmneſs, or Softneſs; and to conduct and carry on his Work accordingly: for in one Caſe the Bank may be made of the Owze itſelf, and in the other, the Matter of it is to be dug upon the Land beyond where the Bank is to be rais'd; and this makes a great Difference.

The firm Owze may be taken up, and rais'd directly into a Bank of due Height and Proportion, for it will dry and grow ſolid in the working. Whereas the wet, ſoft and muddy Owze, cannot be wrought into a Bank, or if it could, would not have Strength to ſtand againſt the Force of the Water.

There is alſo another great Reaſon why the Bank may be made of the hard Owze, and the Earth dug from under it, whereas it cannot, nor muſt, of the ſoft; and this is the different Effect the Sea will take upon a Hole being open'd in one and in the other Kind. When a Hole is made, though ever ſo large, in the hard Owze, the Sea can take no hold upon its Edges, ſo that it does not increaſe in Bigneſs; and as the Ground is firm underneath, it cannot burrow deeper. As this is the Caſe, the Hole is by Degrees filled up by the Sand and Refuſe waſh'd into it by the Water; and ſometimes the Place is render'd level, as if there had never been any Thing done there.

On the contrary, when a Hole is thus dug in the ſoft and muddy Owze, it enlarges continually by the Action of the Water; and if it have been carry'd to any Depth, burrows underneath a great Way. Therefore if any ill-contriving Undertaker ſhould go to work upon a wet and muddy Owze, digging from before the Bank, what he employ'd in raiſing it, he would not only find it very difficult to get a Bank rais'd of ſo bad Materials, and would perceive it to be very bad when made, but the Sea continuing to burrow deeper and deeper in the Hole out of which that Matter was taken, would by Degrees undermine the Bank, and all the Labour would be loſt, and the Expence that had been employ'd ſo unſkilfully, thrown away.

This ſoft Owze may be taken in, and has been, very often to great Profit; the Earth of which the Bank is made being dug within: and if this be the Caſe, as is ſeen by Experience, to how much greater Advantage muſt the other always anſwer.

The Land thus recover'd where there is a firm Owze, is always better and richer than where it has been wet and muddy; and produces a better and more wholeſome Paſturage: and in this Caſe it retains its former Level, either entirely or very nearly, ſhrinking if at all, very little; whereas the other will often ſink two Foot or more in drying.

The ſoft or muddy Owze is found by Experience, to be a better and richer Manure for other Lands than the firm; but that is no Objection to what is juſt aſſerted, and what Experience confirms of the greater Fertility of the dry; for we have ſeen in the Conſideration of Manures in its proper Place, that many Things ſerve excellently for the giving Richneſs to a Soil, which will not afford Nouriſhment to Plants themſelves.

The Proprietors of this Work having been favoured by an unknown Correſpondent, with this Propoſal for the Improvement of Fences, give it to the Publick in the Author's own Words; with a Plate deſigned by Mr. WALE, *from his Original Drawing, and engraved by Mr.* BOYCE.

A Propoſal for the Improvement of Hedge Fences.

INſtead of cutting the full grown Hedge Wood to the Root, on new fencing an Incloſure, and defending the naked Bank with a dead Stake wreathed Hedge, according to the preſent Practice, this Propoſal is made to introduce the Uſe of a Pollard Hedge.

To illuſtrate the Deſcription of this Fence, Reference muſt be had to the Plate A.

The Structure of the Pollard Fence.

Nº 1. Are Stems of the full grown Hedge left ſtanding four Foot high from the Bank, at proper Diſtances; and it would be ſtill an Improvement to have theſe Stems left ſtanding two, three, or more, deep laterally, as well as in the Line of the Hedge.

Nº 2. Are the ſame Stems or Pollards interwoven with ſome of the

the Lops of the old Hedge to thicken the Fence.

N° 3 and 4. Are the ſame Stems or Pollards of ſome Years Growth after cutting Pollard wiſe.

The Uſe and Advantage of a Pollard Hedge Fence.

1*ſt*. The Pollard Hedge will yearly grow thicker and ſtronger. Cutting the Hedge to the Root renders the Shrub weak, and ſubject to decay: whereas leaving Pollard Stems with their lateral Branches (which muſt carefully be preſerved) to the Root, gives Vigour and Spirit of Growth to the Plant; and a ſeeming Sollicitude to recover its late Mutilation, by multiplying at every Eye of the Stem, Branch, and Root: this it does ſo profuſely, that in a very few Years the Fence will be as difficult of Acceſs, as a Wall cover'd with Thorns; and at length the Pollard Stems, &c. will grow ſo obſtinate, that the Strength of a Horſe will be too weak to make a Breach in this ſtubborn Rampart.

Every Hedge, how weak or ſlender ſoever at preſent, may, with great Eaſe, be nurſed into the moſt ſtubborn Pollard Hedge: but the Farmer muſt avoid lopping it too often, leſt thereby the Pollard Stems fail to increaſe in Bulk.

2*dly*. The Pollard Hedge yields to the Tenant, more Fire Wood than any other Kind. It alſo yields a Fence that will require no Expence to maintain, and demands little or no Wood for Bruſh Stakes or Coping, as are expenſively requir-ed in the Caſe of a dead Stake Hedge.

3*dly*. The Pollard Hedge will prove profitable to the Owner, as well as the Occupier of the Land.

At the End of a Leaſe, Fences are generally down, and decayed; and the new Tenant will require them to be repaired at the Owner's Expence. Many Owners have felt the Deduction of a Year's Rent in this Article: let this Intimation therefore be remembered by Land Owners, that it will be profitable to themſelves, and Tenants alſo, to fence their Lands, in their Leaſes, with Pollard Hedges.

CHAP. X.

Of Hedges.

MANY Things have been already ſaid, occaſionally, of Hedges, reſpecting their ſeveral Advantages in Incloſure, and the Benefits which both the Herbage and the Cattle receive from them, in a ſecondary Way, by their Defence and Shelter: we now come to the more immediate and full Conſideration of them.

No Article whatſoever, in the Huſbandman's whole Concern, is of more Importance to him than that of Hedges: they are the firſt Object that naturally ſhould ſtrike his Imagination, as they are the Defence and Guard of all the reſt. We have ſeen how much incloſed Land is preferable to ſuch as lies open; and as this Advantage is originally owing to Hedges, it will be the greater or the leſs, as they are better or worſe managed.

In all incloſed Lands the Farmer muſt keep up a good Fence, if he expect to reap the Fruit of his Labours. For it is by this that his Crops are ſecur'd from external Injuries. 'Tis evident therefore, that the better and the more perfectly the Fence is kept in Repair, the greater will be his Security of his Profits: and we may add, that the Conſequences of one little Defect may do him more Injury, by letting in Cattle upon his Crop, than would have been the Coſt of a moſt perfect and thorough Repair.

As Hedges are the general Fence, it becomes the practical Huſbandman to beſtow his greateſt Care and Thought upon them; a great deal may be ſaved or loſt by a proper or improper Management of them: and in order to make the greateſt Advantage of them, he muſt do ſomething more than follow the common Tract of others: for there is no Part of their Buſineſs in which the Farmers of ENGLAND are generally more deficient.

There are many Shrubs of which Hedges may be made, but there is one Kind almoſt univerſal, that is, the white Thorn. For one Hedge of any other Kind one ſees a thouſand of this. And there is Reaſon for the Preference; for none ſucceeds ſo well, or anſwers the Farmer's Purpoſe ſo perfectly, where the Soil will ſuit with it, which it does throughout moſt Parts of ENGLAND, without Exception.

In ſuch Places as this generally us'd Shrub will not agree with, the Holly, black Thorn, Elder, Furze, and ſeveral others, to be mentioned hereafter, are to be called in; but the common Method is with this. When the Hedge is made with white Thorn, the careful Huſbandman will not think it finiſhed when he has ſet that alone; he will plant in it, at proper Diſtances, Timber, or Fruit Trees, and they will riſe to a conſiderable Profit; but this, like all his other Advantages, will be proportioned to the Care he employs, and to his Attention to the Rules laid down for that Purpoſe.

As to Timber Trees, he is not to plant any at random, for one Kind ſuits one Soil, and another another: nor is there any one that may not be very valuable to him if it be rightly manag'd. In the firſt Book of this Work, where Soils are named, there are general Obſervations laid down of the Trees with which they ſeverally agree beſt: but as the ſucceſsful Growth of theſe depends upon the Depth, as well as the Nature of the Soil; and on many other Accidents, it will be proper for him who is about to plant an Hedge, to begin with obſerving what Trees flouriſh beſt in the Hedges of his Neighbours; for thoſe it will be his beſt Practice to plant in his own.

The Aſh about BRAMPTON in NORTHAMPTONSHIRE, not only thrives better than elſewhere; but it thrives better than any other Kind of Tree in that Place: and the Huſbandman will have three Times the Profit from that he can expect from any other, when he falls upon a Soil that ſuits it in that Degree.

He is in the ſame Manner to ſtudy and obſerve the reſt, taking for his Hedge ſuch as he ſees thrive moſt freely on the Soil: for there is more Profit in the meaneſt Tree, where it thrives, than in the beſt Kind, when it is ſtarved.

In ſome Places it is a Cuſtom to plant Fruit Trees in the Hedges, and they thrive as well as in Orchards: Elſewhere it may be proper to plant Crabs, and Pear-ſtocks, for the Uſe of the Orchard, in grafting Apples and Pears. Even the white Thorn itſelf, is not without its Uſe beſide that in the Fence; for its Root, when of a certain Age, is knotted and veined in a moſt beautiful Manner, and ſerves the Cabinet-makers for many of their elegant Works. This is a Thing mentioned in all the old Books upon theſe Subjects, yet ſo little Advantage is made among us, of what has been written for that Purpoſe, that every body has wonder'd what the STILTON Cabinet-maker made his Tea Cheſts and other Works with, when his only Wood was the white Thorn Root. He had the Secret, as it was call'd, many Years to himſelf, but at this Time it is common in LONDON.

The Huſbandman being thus far adviſ'd, as to the planting of uſeful Trees in his Hedges, we ſhall return to the Subject itſelf; and as the white Thorn Hedge is the moſt univerſal, it will be proper to begin with that, treating of the others afterwards.

CHAP. XI.

Of raiſing the Quickſets for a white Thorn Hedge.

AS this is a very important Article to the Huſbandman, we ſhall take it from the Beginning, ſetting out with his preparing his Sets before we advance to his planting them in his Hedge. In order therefore to accompliſh the Taſk, we ſhall begin ſometime before he intends making his Hedge; for by thus preparing, in Time, he will have all in perfect Readineſs; and ſave the Expence of buying what he may raiſe for himſelf.

Now as he will want, in due Time, a good Quantity of white Thorn Plants, or Sets, let him prepare for them in this Manner. Let him make Choice of a ſquare Piece of Ground, any waſte

Corner will do; and, to chuſe, it ſhould be upon a poor and dry Soil. This he is to uſe as his Nurſery. It muſt be within a good Fence, that Cattle cannot get into it; but there requires no other Care, except that it ſtand defended from the North and Weſt.

In November let this be plowed up, and prepared for the Seeds, and early in the ſucceeding Spring let them be ſown; the Ground having been well weeded during the Winter. The Manner of ſowing them is this.

Let Furrows of five Inches deep be made, at two Foot diſtance, and in theſe ſow the Seeds of the common Haws, gather'd the Autumn before, and kept dry during the Winter. When the Seeds are evenly ſprinkled in, cover them with a Rake; and then leave them to the Time of their ſhooting, which is not till the ſecond Year.

As ſoon as they appear above the Ground, weed them carefully between the Rows, and immediately after give the Ground a good watering. And repeat this weeding and watering at Times, as ſhall be found neceſſary, till the young Plants are got up to a tolerable Height, and their Stems at the Bottom are about as thick as a Man's Thumb.

That is the Size at which they are fitteſt for Uſe. They are to be left ſtanding in this Nurſery till the Bank is prepared for their Reception, as ſhall be directed in the following Chapter; and they are then to be cut off, within five Inches of the Ground, and carefully drawn, that their Roots be not injur'd.

Inſtead of a Nurſery ſome ſow the Seeds of the Haws in their Coppices, the Year before they fell their Underwood; and the young Sets are thus got ready for Uſe without damaging the Wood, or taking up any particular Piece of Ground.

Some alſo prefer raiſing their Sets from Plants, the Seed being a tedious Method of obtaining them. But the Sets are always faireſt and beſt from Seed.

Whichſoever of theſe Methods the Huſbandman chuſes, let him take Care to be provided with a ſufficient Quantity of Sets, of a proper Size, againſt the Time when he ſhall want them; and then the Work is eaſy.

CHAP. XII.

Of the making the Hedge.

THE Huſbandman having thus furniſhed himſelf with a ſufficient Quantity of Sets ready for his Purpoſe, is to take a View of the Ground, and examine its Soil and Situation, that he may know in what Manner to ſet about his Work.

In ſome Places a Quickſet Hedge alone is ſufficient for the Purpoſe; in others a Ditch is neceſſary: this laſt is by much the moſt general Condition; we ſhall therefore enter at once upon the Conſideration of this Kind; the Management of the other being, in a Manner, included within its Directions.

The firſt Thing to be done is to mark out the Courſe of the Ditch, and its Breadth. It is to be three Foot wide at the Top, and its Depth is to be two Foot. Some dig the Sides perpendicular, but that is liable to many Inconveniences; for the Rains will waſh in a great deal of Dirt from the Edges; a great deal more will be thrown in by the Cattles trampling about it; and they can walk and turn about conveniently in it; ſo that they will be continually in the Ditch, and cropping the young Shoots of the Quick.

To prevent this, the Cuſtom of making the Sides ſloping, and the Bottom narrow, was invented, and it is preferable to the other Method on all Accounts. It is beſt to allow but a Foot breadth at the Bottom of the Ditch, when it is a Yard wide at the Top. This will give ſuch a Slant to each Side that the Edges will not ſo eaſily break in; and will cramp the Legs of the Cattle ſo, that as they can neither walk eaſily, nor turn about in the Ditch, they will not get that Habit of going into it.

The Breadth and Depth already-mentioned are, in general, ſufficient for the Ditch in a common Incloſure; but where, from any particular Circumſtances, it is judged convenient to make it larger, it muſt be carried on in the ſame Proportions.

When the Breadth of the Ditch is thus mark'd out, let the Labourer be ſet to dig; and that he may prepare the Bank properly for the Quick that is to be ſet on it, let him lay the Turf regularly, with the graſſy Side downwards, upon that Side of the Ditch on which the Hedge is to be raiſed.

Upon this Turf, thus turn'd Bottom upwards, let him ſpread the beſt of the Mould; and haveing thus prepared a Bed for the Quick, let the firſt Row of it be brought in and laid.

Let the Sets be well choſen, let them be ſtrait, ſmooth, even-growing Shoots, and well rooted: and let them be brought freſh taken up. The Huſbandman ſhould have his Eye upon every Article of this Account, for his Succeſs will depend upon his Regard to the ſmalleſt Particulars The Beauty of his Fence will be altogether owing to the Choice of the Shoots, and their Growth will alſo, in a great Meaſure, depend on the planting.

The Bank being thus far prepared, and the Quick ready, let it be laid carefully in. The Sets muſt be laid on this Bed, at a Foot diſtance; and with the End inclining a little upwards. This is the Method of planting the Hawthorn, or Quickſets; but this is not all that is to be done: The Fruit, or Timber Trees, are to be planted at the ſame Time with the Quick, elſe it will make a Diſturbance.

Let the Courſe of the Bank be meaſured, and at every thirty Foot make a Mark. At each of theſe Marks plant a thriving young Tree of Oak, Aſh, Elm, or whatever Kind is found to ſucceed beſt in the neighbouring Soil; or of ſuch Fruit Trees as will agree with it, taking Care to ſet it upright and ſteady.

One Row of Quickſets being thus laid, let them be cover'd well with ſome more of the beſt Mould; and upon this let there be laid a Covering of Turf, turn'd Bottom upwards, and laid even, and in a workman-like Manner.

Upon this Turf ſpread another Covering of the

the beſt of the Mould, to make a Bed for a ſecond Row of Quick. This Bed is to be in the whole a Foot thick over the firſt Row; and when the Bank is well rais'd to this Height, another Parcel of Sets are to be brought freſh, ſtrait, and well rooted as before directed. Theſe are to be laid in the ſame Manner as the firſt, with the Ends inclining a little upwards, and placed at a Foot Diſtance one from the other; each being laid in the Middle of the Space that is between every two of the firſt Row.

When theſe are carefully laid, they muſt be cover'd with more good Mould, three or four Inches thick, and then the Soil that is dug out of the Bottom of the Ditch, is to be laid over this Earth, and the Bank finiſhed with it.

The Ditch is now dug, and the Earth thrown up is all employ'd, the Quickſets and young Trees are planted, and the Bank is made. The Hedge and Ditch therefore are finiſh'd, and there requires nothing more to be done, but to ſecure them from Injuries.

The very Form of the Ditch has been ſo contriv'd, as to defend the young Quick from being eaten up while ſhooting, but there requires more than this to be done for its Preſervation: it muſt be defended from the trampling of Cattle, and in ſome Degree ſhaded from the Sun. Though the Cattle would not come into the Ditch to eat it up, they would climb over ſuch a Bank as this; and deſtroy all the Work; and the full ſcorching Sun upon the young Sets, would be too powerful without ſome Shade.

For the Defence and Shelter of theſe Sets, a dead Hedge is to be made at the Top of the Bank. This is a Hedge of dead Wood faſten'd by dead Stakes, which being well wrought together, will ſtand very ſecurely, till the Quick is of ſuch a Height and Strength, as to need no Defence upon its own Account; and to be a ſufficient Incloſure to the Land.

For the dead Hedge a proper Quantity of Buſh Wood is to be provided, and a proportionable Number of Stakes. Theſe are the better the ſounder Wood they are made of; and therefore none is better than Oak for the Purpoſe. If Oak cannot conveniently be had, Sallow will anſwer the Purpoſe very well; for this, though a light Wood, is firm and durable; and is found by Experience, which is the only Thing to be rely'd upon on theſe Occaſions, to exceed all other Wood, the Oak alone excepted.

The Materials being thus prepared, the Stakes are to be firſt driven into the Ground: they are to be of ſuch a Length, that they may be thruſt quite through the Bank into the firm Earth below, and enough remain above for the Service of the Hedger; if they do not penetrate four or five Inches into the Soil under the Bottom of the Bank, the whole Hedge will ſtand but an ill Chance.

Theſe Stakes muſt be driven in at two Foot and a half Diſtance, and the Workman ought to ſee that each ſtands firm and faſt. Then let him begin the Hedge. He muſt lay the ſmall Buſhes at the Bottom in ſuch a Manner, that they may cover the Quick when it firſt ſhoots, and be a Defence to it againſt the Bitings of Cattle, that may chance to get down into the Ditch. This is the firſt Care: after this the long Buſhes are to be laid in, and the longeſt of all at Top twiſting them in between the Stakes.

When the Hedge is thus carry'd to its due Height, let a Parcel of long and ſlender Poles be provided, and the Tops of the Stakes bound in with them on each Side; this is what is called in the Country Phraſe, eddering a Hedge: and this finiſhes the Work.

But in order for more full Security, as the Stakes may have been moved in the making up of the Hedge, the prudent Huſbandman will ſee them all well driven again. A few Inches more in Depth gives them now a great Strength, and the Hedge is thus ſecur'd againſt all Accidents, and will ſtand with Eaſe the full Time it is wanted.

CHAP. XIII.

Of the Seaſons for planting Quickſets, and the Choice of the Kinds.

THE Huſbandman has ſeen in the preceeding Chapter, the compleat and exact Method of making a Quickſet Hedge: we ſhall now lay before him ſeveral Particulars relating to the Time for his making, and repairing his Work; the Choice of his Seeds; and other ſuch Particulars; which, although ſome of them may appear leſs important, are all worth his ſerious Conſideration.

There are two Seaſons in the Year for planting a Quickſet Hedge, and only two, for it will not ſucceed in any others. Theſe are early in Spring or late in the Autumn.

For the Spring planting, the laſt Week in FEBRUARY, and the firſt in MARCH are the beſt; for the Autumn, the whole Month of OCTOBER, and the firſt and ſecond Week in NOVEMBER: a Quickſet planted at either of theſe Seaſons will grow, but by what I have ſeen from frequent Experience, I prefer the Spring Plantation. I have always made my own Banks for Quick in the firſt or ſecond Week in MARCH, and adviſ'd the ſame to my Friends, and I may boaſt, that no Perſon whatſoever has planted Quick with more Succeſs.

Two or three Times in my Life, I have try'd the Practice ſo ſtrongly recommended by ſome, of laying in three Rows of Quick into the Bank inſtead of two, but I have never found it ſucceed ſo well. They require that the Bank ſhould be of an unſeemly Height, to keep them at a due Diſtance: and if this be not done, they ſtarve one another.

The Roots of white Thorn ſpread a great Way, as I have ſeen by repeated Experiments; but a great deal of the Nouriſhment is for the firſt three or four Years taken up near the Stem, and in this Caſe the three Rows blend their Roots together, and deſtroy the Growth of each other. Of this I am certain, more Wood will be produced in the ſix firſt Years from two Rows, than from three.

In Places where the young Quick will be too much expoſed to Cattle, there muſt be a dead Hedge on the Edge of the Ditch, as well as on the

the Top of the Bank. This is an additional Expence, but it keeps the Work ſecure, and gives the Quick Leave to ſpring without Moleſtation; and the Succeſs is always ſpeedier, as well as greater.

When the Quickſet Hedge is to be made without a Ditch or Bank, the Plants are to be diſpoſed in a different Manner from that uſed in the common Way of working. They are to be ſet nearly upright in two ſtrait Rows by Line, and about a Foot Diſtance one from another. They will thrive this Way very well; but ſhould be fenced with a high dead Hedge on both Sides, for they are more expoſed to Miſchief of every Kind, than the others.

Moſt Soils and Situations will bear the Hawthorn, and whenever it will thrive tolerably, it is preferable to any other Shrub by way of Fence. Where there is too much wet, or where the Soil is perfect Sand, it does not ſucceed; but for theſe Places other Shrubs will be propoſed in the ſucceeding Chapters.

If the careful Huſbandman will look into the Hedges, he will ſee there is a manifeſt Difference among the Hawthorn Shrubs; ſome having more ſome fewer Branches; and ſome much larger Leaves than others. As I have adviſed him to have a little Nurſery for the raiſing his Sets, I ſhall here add a very material Piece of Advice, though little regarded in general; that is, that he gather the Haws for Seed himſelf, and that he take a particular Notice from what Shrub he gathers them.

He will find that the Hawthorns with ſmalleſt Leaves have the moſt Branches, and the greateſt Number of Thorns. Theſe therefore will be ſure to make the beſt Fence: and I have obſerv'd, that they are the ſturdieſt, and leaſt liable to Accidents while young.

Let him gather his Haws when they are well ripen'd, from one of theſe ſmall leaved buſhy Shrubs, the ſmaller leav'd and more buſhy, the better; for the Sets will follow the Nature of the Parent Tree, or improve upon it; eſpecially as I have directed the Nurſery for the raiſing them to be upon a poor Piece of Ground: for Richneſs in the Soil tends to throw the Nouriſhment in all Shrubs into the Leaves, and not into the woody Part.

One Reaſon therefore of having the Nurſery upon a bad Piece of Ground is, that from the Seeds of a buſhy ſmall leav'd Hawthorn, the Sets may continue of that Kind; but there is another much more material, which is, that on this Circumſtance depends in a great Meaſure their thriving in the Hedge. For this is a certain Rule, that young Trees when they are taken out of a rich Soil, and planted in one that is poor, never thrive well: and on the contrary, ſuch as are tranſplanted out of a poorer Soil into a richer, grow ſurprizingly. Now the Banks on which Quickſets are planted for Hedges, rarely are of an over-rich Soil; ſo that the Way to have the Sets thrive, is to raiſe them in one that is yet poorer.

The Poorneſs of the Soil is alſo the more needful, in order to raiſe the buſhy Hawthorn from its Seed without Failure, becauſe this is not a diſtinct Kind of Hawthorn, but only what the Curious call a Variety; ſo that if the Seeds of this be ſown in a mellow rich Land, they will produce a ſtragling, looſe, and large leav'd Shrub, as I have ſeen by Experience.

CHAP. XIV.

Of keeping the Hedge in order.

THE Method has been now laid down, not only of making a Hedge; but of doing it in the moſt profitable Manner, in reſpect of every Article in that Concern. We will ſuppoſe it now made; and proceed to the neceſſary Care of it under its natural and accidental Damages.

The next Spring after the laying of the Quick, let the Farmer go over the whole Bank with a careful Eye. Firſt examining the dry Hedge at Top, whether it be firm in every Part. If he find it looſe any where, let this be remedied by driving a new Stake, or faſtening the old ones: and if any other Deficiency appear, let him ſee it repair'd in the ſame Manner. A very ſmall Expence will do this the firſt Year, whereas it might be ten-fold the next: and the going over it at the End of one Year in this careful Manner, will often ſecure it for its Time.

When he has rectified what was amiſs in this, let him view deliberately and ſeparately, the Quickſets. Some of theſe, in Spite of all his poſſible Care, will fail; ſo that he will on this Examination find ſome dead, and others in a declining Way. He muſt now ſee freſh Sets put in the Place of the dead ones; and trim up the others with due Care.

Some adviſe the Planting the Fruit or Timber Trees in the Hedge at this Time; and others recommend the doing that, when it is at two, three, or four Years Growth: but from what I have ſeen in Practice, I greatly prefer the planting them at the making of the Bank, at the ſame Time with the Quick: for thus they take their Growth together; and there is no Diſturbance of the Fence, as there muſt be in planting them when all is ſettled.

Before the Farmer takes a View of his young Quickſet, let him order it to be weeded. This muſt be done carefully and thoroughly: and it muſt be repeated at Times, for the Quick, while it is young, ſhould have all the Nouriſhment the Ground can yield, and not be ſtarved by the Weeds. This clearing will give the Owner a diſtinct View of the Condition of the Sets, that he may know what to ſupply.

At this Time while the Shoots are young, too much Care cannot be taken to guard them from Sheep: for they are very fond of the tender Buds: and their cropping them at this Period of their Growth, is particularly deſtructive.

If by any Accident Sheep have got at it, or other Cattle, it will be diſcover'd by the Tops being eaten off, and crop'd irregularly, and mangled at the Ends. In this Caſe there is but one Method to reſtore any Hope of a good Hedge: the whole Growth muſt be evenly cut off, within an Inch and half of the Ground; and there will then be a new and freſh Set of

Shoots,

Shoots that ſpring, which would not have happen'd from the gnaw'd Ends, at leaſt not with any Degree of Regularity or Beauty.

If the Weather have been unfavourable, or the Soil too poor; or if from any other Accident the Shoots are perceived to be weak and bad: the ſame Practice is to be obſerv'd as in the other Caſe: they are to be cut off within an Inch and half of the Ground. This will give the Roots new Strength; and the ſecond Shoot which follows this, will not be ſo faint. I have ſeen a very languiſhing Quick perfectly reſtored by this Method.

From this Time very little Care is required till the Hedge is of a Growth for plaſhing; this is not till eight or ten Years after the Planting, and is an Operation that ſhall be treated of ſeparately in another Chapter. But though little Care be required during the firſt Year's Growth of a Quickſet, leſs than that little uſually is taken, for many give themſelves no Trouble about it at all.

Let the induſtrious Huſbandman do otherwiſe. Let him from Time to Time look to it; and remove its Redundances, and ſupply the Defects. Let him with his Knife take off ill-ſhap'd and ſtragling Branches. Let him ſee that no unneceſſary dead Wood be left at the Bottom, for that will choak the Quick. And let him carefully root up all thoſe tangling Weeds, which are ſo common in Hedges, and at once ſpoil their Beauty, and injure their Growth.

The principal of thoſe Weeds which are deſtructive to Hedges, are four. White Bryony, Black Bryony, Travellers Joy, and Bind Weed: theſe all cover the Hedges to a great Extent.

White Bryony has Leaves like a Vine, and red Berries. The Root is as big as a Man's Leg, and whitiſh; it muſt be dug out deep, for it runs a great Way into the Ground; and if any Piece be left, will ſhoot from it. Black Bryony will grow thirty Foot long, and entangle and choak the Quick all the Way. It has Leaves like a Heart, and the Root is thick, black on the outſide, and white within. It muſt be dug up like the former.

Travellers Joy has woody Stalks, and ſpreads a great Way. The Leaves are ſmall, and of a pale Colour; and it bears white thready Tufts in Autumn. It is more deſtructive of the Quick than any of the others; over ſhadowing it in the Manner of an Arbour. The Root of this is not large, nor lies deep like the others; but the Farmer muſt take Care he gets it up entire, for the leaſt Piece of it will ſhoot again; and the Buſh is of quick Growth.

Bind Weed is the ſmalleſt of theſe Weeds, but it will crawl among the Branches to fifteen Foot length; it has Leaves ſhaped like the Head of an Arrow, and bears in July large white Flowers like Bells. The Root of this Weed is ſlender and white. It does not go deep, but runs a great Way under the Surface of the Ground; and ſhould be got out entire, for the leaſt Piece of it will grow, and ſend up new Stalks.

All theſe Weeds ſhould be watch'd in their young State, and tore up before they come to flower or Seed; for after that there will be an eternal Brood of them: but if they be thus deſtroy'd, all the Farmer will have to do is, to watch the Riſe of ſuch as come from chance Seeds, and they are but few.

By theſe Directions; but chiefly by keeping a watchful Eye from Time to Time upon the Growth itſelf, the Farmer will raiſe his Quickſet Hedge in Strength and Vigour: and by as much as it is handſomer to the Look than thoſe of his Neighbours, ſo much it will be better, and more healthful. We ſhall now leave it to grow to the eighth Year, or thereabouts, and then proceed to the Plaſhing of it.

CHAP. XV.

Of Plaſhing a Hedge.

THOUGH the Plaſhing of a Hedge is to be firſt perform'd at about eight Years Growth, this is not the only Time. It is to be repeated afterwards at different Periods; and as there is more Art requir'd in this when an older Hedge is be plaſh'd, than when it is a young one, we ſhall beſt inſtruct the Huſbandman in doing this to the greateſt Advantage, by deſcribing the Method to be obſerv'd when it is old. What is to be done in plaſhing of a Hedge of twenty, or five and twenty Years old, includes all that can be needful to know for doing it on one that is younger; but on the contrary, more is required for the old than need be done to the young.

We will ſuppoſe the Hedge planted and dreſſed, as already deſcrib'd, to be grown to five and twenty Years ſtanding. It will by this Time be looſe and irregular in its Growth, there will be Vacancies at the Bottom, and Gaps in many Places, and it will be full of thick and old Stumps, and Stubbs, as well as of young Shoots. Theſe latter only are for Uſe: the others are to be cut up, for they encumber the Hedge, and prevent the Growth of better Wood.

Upon a View of the Condition of the Hedge, the Huſbandman is to conſider in what Manner he is to go to work. The Stubbs are declared uſeleſs already; but among the reſt he muſt conſider, that he is to reſerve ſome Shoots for laying down, and others to ſerve by way of Stakes. For the firſt Purpoſe he is to ſelect thoſe which are longeſt, and freſheſt; and ſuch as are of a middle Growth: for the Stakes, he is to leave ſuch as are ſomewhat larger, and ſtand properly, and grow tolerably ſtrait for the firſt five or ſix Foot: it matters not for the reſt, becauſe they are to be cut off at that Height: their Uſe requiring no more.

When the Huſbandman has thus conſider'd, let him go to work. He is to cut away all the old Stubbs within two Inches of the Ground, ſtriking them off ſloping. After this let him go on thining his Hedge, by cutting away all but the proper Shoots for Stakes, which he is to ſtrike off at the Height he deſigns his Hedge, and the long Shoots for laying, which he is to leave entire.

As there will not be enough of theſe Shoots

for Stakes, growing as they ſhould do; he muſt make ſome others to drive into the Ground, where there is a Deficiency.

When the uſeleſs Stuff is thus cut away, a Spade may be got between the Shoots; and the Labourer is to be employed to clean away and new make the Ditch. Let him dig this juſt as it was at firſt; making the Top wide, the Bottom narrow, and the Sides ſloping.

As he is at work upon this, let him clean away all Filth from about the Roots of the Quick; and where the Earth has moulder'd away from them, add ſome of the beſt that comes out in digging the Ditch, preſſing it well into the Hollows. It is impoſſible to conceive, but from one's own Sight, what a Refreſhment this cleaning and digging of the Ditch, gives to the Roots of the Shrubs. A vaſt many ſmall Roots are cut off, and they might be ſuppoſed hurt, but they ſoon ſend out many more. The ſtirring of the Earth about them is of vaſt Service; and thus the Roots having a greater than ordinary Supply of Nouriſhment, and having a ſmaller Quantity of Wood to feed, that which is left flouriſhes ſurprizingly.

A great deal of the better Mould from the Ditch, will be thus us'd in filling up Holes, and facing of the Bank, the reſt is be laid at the Top: for if the Sides be loaded they will break with the Rains, and what falls off will choak up the Ditch. And as it would be only hurtful thus laid on the Sides: it is of great Service when laid on the Top, heightening the Bank, and greatly improving the Fence. The Labourers don't like to hear of this, becauſe it gives them more Trouble, but it is the Maſter's Buſineſs to ſee it done. He who pays them is not to ſuffer by their Idleneſs.

We have directed, in the making of the Hedge, that either Fruit or Timber Trees ſhould be planted at proper Diſtances. Theſe the Huſbandman is to leave ſtanding among his Shoots. They have nothing to do with the Hedge, though they grow among it; and they are to be lop'd in the uſual Manner, if Timber Trees: and if Fruit Trees, to be prun'd up above the Reach of the Cattle: and all that is to be done to them at theſe Repairings of the Fence is, that partly by this pruning, and partly by ſtaking, if neceſſary, they are to be brought to ſpread and lean over the proper Ground, where both Sides of the Hedge are not the Owners.

The Ditch is now clean'd, the Bank repair'd, and the Stakes ready. Let the new ones be well and firmly driven, where there are not a ſufficient Number of the upright Shoots left for that Purpoſe: and theſe being diſpoſed, the Work is ready for the Plaſher.

He is to take each of the long Shoots which be left ſtanding ſeverally, and bending it gradually he is to give it a ſloping Cut with his Bill half through; it will then fall eaſily, and he is to weave it in between Stake and Stake carefully.

When he has thus work'd in all the Shoots left for that Purpoſe, he is to go over his Work, and trim off the ſtraggling Sprigs, to render it uniform and even.

A great deal of the Succeſs of this Work depends upon the Method of laying theſe Boughs, when they are cut through ſo far as to obey the Hand of the Workman. If they be laid too low and too thick; as many do, thro' an Opinion of its ſtrengthening the Hedge, the Sap is all ſent into the Shoots; and the Plaſhes ſtarve and will decay. On the other hand, if they be laid too high, then they draw in all the Nouriſhment; and the Shoots are ſtarv'd. Both theſe Accidents are to be avoided by a middle Courſe. It is not the Farmer's Intereſt to ſtarve the Shoots to feed the Plaſhes, nor to ruin the Plaſhes for the Shoots: he is to derive a proper Quantity of Nouriſhment into both; and this will be done by laying them in a middling Way. Beſide this has another Advantage; that if the Plaſhes are not too deep cut, and are laid thus evenly, or nearly upon a Level, the Sap is not all directed to their Ends, but ſends up Shoots from every Part.

This Abundance of young Shoots will alſo be promoted by the proper cutting of the Branches of the plaſh'd Boughs. They are to be cut off ſhort, at five or ſix Inches length on each Side of the Hedge; and this will make them ſend out Side Shoots of their own, as well as promote the Growth of the others, to the great Beauty and Strength of the Hedge.

Many have a Cuſtom of making their Hedges too high: but this is wrong for ſeveral Reaſons. Let the Bank be rais'd carefully and firmly; and let the Hedge be made juſt high enough to ſerve as a Fence, and no more; for it will quickly raiſe itſelf higher: and always in thoſe Hedges which are too high, the Quick is ſtraggling at the Bottom. The lower the Hedge the more free the Shoots always grow, and the thicker and cloſer the Fence is at the Bottom.

A Hedge muſt be of a conſiderable Growth to require this full Care and Nicety in the plaſhing: when it is younger the Buſineſs is done with more Eaſe and leſs Ceremony: but on the other hand, the Huſbandman has ſometimes to do with an Hedge that is too old to be repaired by plaſhing, with all the Care he can take; or by the niceſt Obſervations of theſe Directions.

In this Caſe there is but one Thing to be done. Let him cut up all the Stubs, and make a good dead Hedge on each Side, to ſecure the young Shoots that will riſe, till they are of a proper Height to plaſh. As there will be Vacancies between ſome of the Stubs, theſe are to be ſupplied by freſh Sets, which will grow up with the Shoots from the Stumps, and the dead Hedges are to be kept in Repair till theſe are of an Height to be uſeful.

When an Hedge is new plaſh'd it ſhoots out very vigorouſly, and theſe freſh Branches tempt the Cattle. It is therefore always beſt, if the Field can be kept from feeding the firſt Year at leaſt. If it can be kept for mowing, this anſwers ſome Purpoſe, but if plowed, it is of twenty Times the Service; becauſe that ſtirring and turning up of the Ground gives Vigour to the Roots of the Quick, and forwards the Shoots prodigiouſly.

This may inſtruct the Farmer to ſuit his ſeveral Buſineſſes to one another. He is never ty'd down to a particular Year for the plaſhing of an Hedge: let him therefore take the Opportunity of doing this when the Ground is to be plowed,

plowed, at leaſt when it is to ſtand for Hay.

If he cannot do this; for Things will ſometimes fall out croſly, let him remember what Cattle are moſt and what leaſt miſchievous, that if he muſt feed the Ground it may be to the leaſt Diſadvantage that may be. Horſes, of all other Animals, are leaſt apt to crop the Quick. Cows and Oxen are too fond of it: but Sheep moſt of all. They are therefore to be kept out of the Ground, for the firſt Year at leaſt if poſſible, with any Degree of Conveniency.

As to the Seaſons of plaſhing of Hedges, there is but one proper. Some do it in October, and pretend particular Advantages from that Time: but let the Huſbandman truſt to Experience, and aſſure himſelf that the only right Seaſon is the Month of February.

While the Hedge is growing up from the plaſhing, it will be proper to have the ſame Eye upon it as at firſt; taking Care, in Spring and Fall, to cut away the ſtraggling Branches, and to root out Weeds: thus the Fence will grow regular, thick and clean; and from this renewing, in the ſame Manner as from its firſt Riſe, will exceed, in every Reſpect, thoſe of the Neighbourhood, which are not looked after with the ſame Degree of Care.

We ſhall add only two or three ſlighter Admonitions here, and then conclude this Chapter. When the Hedge is plaſh'd, the Shoots laid down, and wove in, and the ſtraggling Branches of them are going to be cut away, let there be a Reſerve made of the fineſt, tougheſt, ſlendereſt, and longeſt of them. Inſtead of cutting theſe away let the Workman bend them to his Purpoſe, and to that End give them a Nick at the Bottom, if neceſſary, and then bind in the reſt with them. This finiſhes the Hedge beautifully and durably. After this the whole Work may be, at Times, over-looked, the dead Stakes driven a little down, and the plaſh'd Boughs preſs'd alſo gently lower: all which will make the Hedge more firm and durable: and where from Neceſſity, or Accident, there is no keeping Cattle away, it is a good Practice to ſcatter ſome dead Thorns over the Top of the Hedge, and about its Bottom, by way of Defence, till the young Shoots have ſome Strength.

When in a very old Hedge the Stubs are ſo large that they break in upon the Uniformity of the whole, and are liable to make Gaps by the Cattle getting by, at one Side or other of them, the Method is to cut them ſo nearly through by the Ground, that they may be bent down; they are then to be ſway'd till they can be laid ſlanting, the Head of one upon the Stump of another; and the natural Vacancy in the Slant is to be fill'd up with the Side Shoots. By this Method, and by keeping the Bank high, and in good Repair, a Fence may be made out of very unpromiſing Materials; but in general it is better in theſe Caſes either to cut down the Stubs, as before-directed, making a dead Fence on each Side, waiting for a freſh Shoot from the Roots; or elſe when the Caſe is moſt deſperate of all; as when the Roots are extreamly old, and ſtand very ſtraggling, to ſtub the whole up entirely, and begin from the Foundation, making a new Quickſet as firſt directed.

CHAP. XVI.

Of the Profits that may be made by Hedges.

SO familiar and ſo eaſy is the making and preſerving a Quickſet Hedge, according to the known Methods, when the Huſbandman will be careful to enquire by reading, and by queſtioning his Neighbours, what all thoſe Methods are; and will be induſtrious enough to ſee them all put, in a proper Manner, in Execution, under his own Eye. He is not to content himſelf according to the common Cuſtom, with giving his Orders, and leaving all to the Care of idle Labourers, and negligent Servants. They are not to reap the Advantages, and they cannot be expected to take the Care. But he is inexcuſable who is to have all the Profit; and who will not overlook the Work, and ſee if it be done in the moſt beneficial Manner.

From the little Care that is taken about the hedging Work, it appears to me very plainly, that the Profits which may ariſe from it are not known: I ſhall therefore ſpeak what my own Experience has ſhewn me on that Head, in order to ſtir up the Huſbandman's Spirit.

This is certain, that it is the Landlord's Intereſt to plant or to promote the planting of Fences in this Kind, becauſe, as obſerved before, the Rents of his Eſtate are ſure to be encreaſed by it: and I ſhall ſhew that it is not leſs the Tenant's Intereſt than his. I know ſeveral who will grudge to ſerve their Landlord when it turns to no Account for themſelves, may be brought into it when they find it will anſwer their own Purpoſes alſo. And upon this Plan there will be no Oppreſſion in a Landlord's inſiſting upon a Covenant of Fencing, in the Leaſe, when the Tenant will himſelf reap the Advantage for his Time; as the Owner does in all theſe Caſes for ever.

If Hedges were of no other Uſe except as Fences, it would be the Farmer's Intereſt to keep them up carefully: for the better the Fence is, the greater is his Security of his Cattle and Crop. But in many Counties of England the Hedge yields a valuable Store of Fruit; and it might do ſo in all; for this being partial is owing to Cuſtom only, the ſame Advantage is allowed to all by Nature.

The Shelter alſo of his Hedges, which we have ſhewn to be ſo uſeful both to the Crop and Cattle, is ſurely the Tenant's Benefit: but the greateſt Inducement is behind, that is, the abſolute Profit; which, for want of Induſtry and Application, few know. In reality they rob themſelves of a great deal of Money, by their Careleſſneſs in this, as well as other Articles; for it is as much their Intereſt, in this View alone of the Wood they will yield, to raiſe, cure, and dreſs their Hedges, as to tend and to take Care of any other Part of their Stock.

Mr. Ellis, who is a Perſon of Veracity, affirms from his own Knowledge, that a Farmer in Hertfordshire, who occupied only ſixty Acres of Land in incloſed Fields, made in one Seaſon a thouſand Faggots from his Hedge-wood only, which

which he ſold for about twenty Shillings a Hundred. This I have great Reaſon to believe, for I have ſeen nearly as much Profit in other Places, where the Quick does not grow ſo freely, nor is ſo well underſtood in hedging as in HERTFORDSHIRE, which is, in that Reſpect, the Garden of ENGLAND.

CHAP. XVII.

Of the Sloe, or black Thorn Hedge.

IT has been ſaid already, that although the Haw, or white Thorn, is the moſt general Shrub us'd in hedging, and the beſt for that Purpoſe in moſt Places, yet it is not univerſal, nor abſolutely ſuited to all. There are Soils in which it will not thrive; and beſide this, there are Circumſtances which may render ſome other Kind preferable, even in Places where that would grow ever ſo well. This is the Source of thoſe other Fences to be deſcribed in the preſent and ſucceeding Chapters.

The black Thorn is the next in Value to the white, in a Quick Hedge. And it is preferable to that and to all other Shrubs, for a dead Hedge, becauſe it is, of all Shrubs we have, the moſt thorny, durable, and naturally buſhy.

The Ground can never give a Reaſon for planting black Thorn, and not white, for they will both grow and thrive in the ſame Soils; and if any thing the black Thorn requires a better: but notwithſtanding this, we have already mentioned a very ſubſtantial Reaſon why the good Farmer ſhould plant it.

He will always ſucceed better in proportion as he conſiders every Circumſtance, and every poſſible Advantage. We have obſerved, that no dead Fence is ſo good as that made of black Thorn: for this Reaſon the Perſon who ſees that he ſhall have Occaſion for a good deal of dead Hedge, at any particular Time, or upon any particular Occaſion, will do well to plant at leaſt ſome Quickſets of black Thorn, if not all; and this, that the Cuttings, and ſuperfluous Stuff riſing from them may afford him a ſufficient Supply of that excellent Buſh, for the Purpoſes that have been already mentioned.

When the Farmer has this Reaſon for planting a Quickſet of black Thorn, let him conſider his Soil before he ſets about it. More is required than his having Occaſion for the Buſhes, he muſt know that the Ground will bear them.

In the firſt Place he is to be inform'd, that a very poor Soil will not do for this Shrub, and that in a very rich one it is apt to ſhoot too deep, and ſpread too far into the Ground, to the Hurt of other Things. I have ſeen more Hedges of live black Thorn miſs, than of any other Shrub whatſoever: this has been ſometimes owing to the Badneſs of the Ground, but oftener to the Unſkilfulneſs or Negligence of the Perſon employ'd to plant it: and I have, in other Places, where ſuch an Hedge has throve very well, ſeen all the other Growths ſtarved within a great Way of it, merely by the Quantity of Nouriſhment it exhauſted.

When the Huſbandman ſets out with this Foundation of Knowledge, concerning the Nature of the Shrub, he will be able to work on it to his Advantage. Therefore, when ſuch an Hedge is to be rais'd, let him chuſe a Part of his Land where the Soil is rich, but not deep. A two Foot Coat of Hazel Mould upon a Bed of Stone, or a Layer of Clay is beſt; if any ſuch offer upon the Land, the Farmer will be ſure to raiſe an excellent Fence, and to do himſelf no Harm in his other Products.

Let him, in this Caſe, prepare for planting his Hedge exactly as has been directed for the white Thorn; only let him dig the Ditch half a Foot deeper, that it may go a Foot and a half, or more, into the under Layer, to ſtop the direct Progreſs of the Roots into the Land. It is true, they will, on theſe Occaſions, ſink down below the Bottom of the Ditch, and riſe up again on the other Side, but not in ſuch Quantity.

I would adviſe the Huſbandman to prepare for his black Thorn Hedge exactly in the ſame Manner as for the other. Firſt of all, let him, ſome Years before hand, turn up a little Piece of Ground in ſome waſte Corner, ſow it with the Stones of Sloes, and fence it well in, weeding the Plants now and then, after they are come up, which will not be till the ſecond Year after ſowing; and letting them ſtand till they are of a Size for Sets.

When they are thus ready, the whole Practice is to be exactly the ſame as for the white Thorn Hedge. And there is this Advantage when they are carefully ſet, and the Defects ſupplied after the firſt Examination, that they grow much quicker than the white Thorn to a certain Standard; and being more prickly, and not ſo well taſted, they are not ſo liable to be crop'd by the Cattle as the white.

There is a conſiderable Advantage in raiſing the Sets in a little Nurſery of this Kind, they grow ſtraiter and better; and when they are removed to a richer Soil, which ſhould always be the Caſe, their firſt Shoots are much more vigorous. The Farmer will do well when he takes up the Sets for his Hedge, to leave ſeveral ſtanding at proper Diſtances in the Nurſery, becauſe, by this Means, he will have a Supply of the Buſhes for ſtoping up of Gaps, and other ſuch Uſes, for which they ſerve better than any other Kinds, before his Hedge affords them from the Cuttings.

CHAP. XVIII.

Of the Furze Hedge.

WE have mentioned, in the Sloe, a Kind of Hedge which will very well anſwer all the Purpoſes of a Fence, and which there may be particular Reaſons for planting, even in Places where the Huſbandman might, if he pleaſed, raiſe the common white or Hawthorn: we come here to ſpeak of a Shrub which is alſo very excellent for making a ſafe and durable Fence, which, at certain Seaſons of the Year, is alſo very beautiful; which always makes a pleaſing Variety among other Incloſures; and which has this greater Advantage, that it may be rais'd in Soils

and Situations where neither the white nor black Thorn will grow.

So much may be conjectur'd from what is ſeen in Nature. For we conſtantly in many Parts of ENGLAND, ſee the Furze Buſh growing wild in vaſt Abundance, upon ſandy, heathy, and barren Commons; where only here and there a black or white Thorn Shrub pops up its Head, and thoſe half ſtarv'd.

It has been obſerv'd already, that there are two Soils in which the white Thorn Hedge is not to be planted; theſe are very wet, or very dry and ſandy. What the Farmer is to ſubſtitute for it in the wet Places, will be named hereafter; the Furze is the proper Shrub for the dry and barren; for there is no Piece of Ground ſo barren on which Furze will not ſtand.

Where there is therefore a Piece of Land to be enclos'd, from ſome exceedingly barren Heath; or where the Place for a Fence is ſome old dry and mouldering Bank of almoſt entire Sand; or where the Ground is ſo entire a Gravel, that it ſcarce deſerves the Name of a Soil, there this Shrub is the Choice, and will ſucceed perfectly well. The worſt Objection to it is, that it does not laſt a great while: but then it is eaſy to be renewed, and it makes an excellent Fuel. Perhaps if we would copy the FRENCH, whom we are apt enough to imitate in Trifles, in their Management of Furze, planting of Hedges of it of thirty or forty Foot thick, in Places where the Ground is really not worth Culture, as in abſolute Sands, and entire Gravels, we ſhould reap an Advantage little imagin'd. To our good Fortune we have not ſo much Ground of this Sort as they, but where there is ſuch, it might better be uſed to this Purpoſe than to none; planting the FRENCH Furze, which grows five or ſix Yards high, and does not require any Care after the firſt Year or two.

They find theſe thick Hedges a prodigious and favourable Shelter for their Game; which is there the Property of the Farmer, as much as his Poultry; and they cut it up in the End for Fuel.

A dry barren Soil, and an expos'd Situation, is the Place for a Hedge of Furze. Where the Farmer has ſuch an Occaſion, let him not pretend to plant any other Shrub for that Purpoſe: nor in this is he to proceed in the ſame Manner as with the others.

Here is to be no Nurſery for raiſing the Sets, for there need be no tranſplanting. The Shrubs muſt be rais'd from Seed in the Places where they are to remain; and the Method is this.

In the Place where the Hedge is to ſtand, let the Ground be plow'd up deep in Winter, and let it lie in that Condition till the End of MARCH. At that Time let it be once again plow'd, and then harrow'd, to make it as even and fine as may be. When this is done, that is, in the very Beginning of APRIL, go carefully over the prepared Ground, ſowing it with well choſen and fine Seed, of that Kind called FRENCH Furze Seed.

When the Seed is in the Ground, let a dead Hedge be planted on each Side. It need not be a very ſtrong one, for it will be neceſſary only three, or at the utmoſt four Years. The Seeds will ſoon ſhoot, and the Plants when riſen to ſome little Height, are to be thin'd and weeded. They are to be kept weeded from this Time till they are become tolerably ſturdy, for then they will not ſuffer Weeds about them; and in three or four Years there will be a very ſtrong and beautiful Fence without any farther Trouble.

As the Furze Hedges require leſs cutting than the other Kinds, ſo they will very little bear it. It is ſeldom needful to cut ſuch a Hedge in Fields at all; and thoſe over-nice People who will do it, often deſtroy the Plantation. If the FRENCH Furze Seed be ſown, it rarely grows out much beyond the Bounds that were intended, for this Kind does not ſpread and run like the others: but if it happen under any particular Situation that it ſhould do ſo, the beſt Way is to cut it up cloſe to the Ground, and leave it to ſhoot again from the Roots.

In this Caſe it muſt be defended as at firſt, and it will ſoon ſpring up in greater Regularity. If the Circumſtances will not admit of thus cutting it up; and it be needful to reduce it to Bounds; this muſt be done by cutting: but as that is in itſelf ſo hazardous, great Care muſt be taken in the Manner of doing it. The principal Cautions are theſe.

If Furze be cut too cloſe into the old Wood, it will never ſhoot out again, ſo that when altogether needful to cut it, that muſt be done lightly. The Seaſon muſt be greatly regarded alſo, for nothing is ſo liable to Accidents from the Weather as freſh cut Furze. If cold follows, it certainly kills the Branch that has been wounded, and often the whole Shrub: therefore it muſt not be cut either too late in Autumn, or too early in Spring, for the Froſts may be deſtructive.

On the other hand, if the Furze be cut in extreamly dry Weather, the ſame Accidents follow as from Froſts, the dry Winds attacking the freſh Cut, part and deſtroy the whole.

For theſe Reaſons 'tis much beſt, as before obſerv'd, never to cut one of theſe Hedges at all; but if it muſt be done, the only Seaſon is the middle of APRIL, and then in perfectly moderate Weather.

Whether a Furze Hedge be new rais'd from Seed, or whether from the old Roots after cutting down, no Fence whatſoever requires ſo much Care in the guarding of it from Sheep, while it is firſt ſhooting. When young, they are extreamly fond of it, for the Buds are ſoft and juicy, but when it has got a little Strength and Firmneſs, its own innumerable Prickles are a full Defence.

One farther Advantage of a Fence of this Shrub, is not to be omitted; that is, it will grow not only on barren dry Sand, but on the barren and naked Sea Sand, as well as the Native Sea Plants. This points out a very great Uſe for it, which is in the making of Fences, where every Thing elſe refuſes to grow: theſe Places being generally ſuppoſed not capable of fencing by Hedges.

Scarce any Cattle will attempt to crop a Furze Hedge of ſome Growth, which has occaſion'd ſome to imagine, that it is unwholeſome, moſt Creatures having a natural Direction to

avoid all ſuch Herbs as are hurtful; but this is a common Error. There is nothing to cauſe this Shyneſs of Cattle to it, but the Pricklineſs of its Branches, for no Plant is more wholeſome. They ſow the French Furze in ſome of our Weſtern Counties, on Land that will bear nothing elſe; and among other Uſes, the green Tops are chop'd ſmall, and given to their Horſes. This chopping deſtroys the Pricklineſs, and the Creatures are then very fond of them, and very well nouriſh'd by them.

CHAP. XIX.

Of the Holly Hedge.

HOLLY is another of thoſe Shrubs which will grow in very indifferent Soils, where the white Thorn will either not grow at all, or but very indifferently. But this is not the only Reaſon there is to value it. Nothing makes a ſtronger or a better Fence. But it is ſlow in its Growth at firſt: every Thing has its Advantages and Diſadvantages.

I have ſeen old Holly Hedges in the Country make a very poor Appearance, and ſome grown quite out of Uſe; but ſo will Hawthorn, or any other, if neglected. The ſame Care that is required for others, is alſo wanted for theſe, and no other. If that be omitted, all the Hedges in the World will, after a certain Age, grow uſeleſs.

Holly loves a light and dry Soil: and it will live on the moſt barren. It has been ſaid already of Furze, that it will grow on a dry Sand, or entire Gravel, the ſame is true of Holly: but between the two there is this Difference, that the Furze is the beſt ſuited to ſandy, and the Holly to gravelly Grounds.

There is alſo another Kind of Soil, too common in many Parts of England, this is the ſtony. In this the Hawthorn is ſtarv'd, and the Roots even of the Furze are burnt up. The Holly will thrive and flouriſh upon this, and it is the only proper Shrub for a Fence on thoſe Grounds. It may be uſed on many others, but no other can be uſed on ſome of theſe. It loves Warmth and Dryneſs about the Roots; and will grow almoſt upon a Rock.

The Farmer ſees on what Soils he may, and on which he ought to uſe the Holly as a Fence. We ſhall now teach him the beſt Manner of raiſing, and preſerving it in this Condition.

Holly is one of thoſe Shrubs whoſe Seeds lie two Years in the Ground; but there is a Way of helping the Tediouſneſs of this. The beſt Method of raiſing the Sets is this.

Gather the Berries when they are full ripe, and begin to fall from the Tree, and laying them upon a large coarſe Cloth, rub them gently with another to break them, and wipe off the tough Juice from the Seeds. They need not be made curiouſly clean, but a great deal of this uſeleſs Matter may be taken off with little Trouble.

When the Seeds are thus clean'd, mix them with ſome dry Sand. Fill a large Garden Pot with this Mixture, and digging a Hole in the Ground bury it there. Let them lie thus from the Autumn when they were gather'd from the Tree, till the Beginning of the September following. Then take up the Pot; prepare a Bed of good light Earth, and ſow the Seeds in it, covering them ſlightly with a little of the ſame Mould ſifted over them. They will ſhoot the next Spring, and thrive, though it be ſlowly. They make very little Advance for the firſt three or four Years.

This is the Method of raiſing Holly; but there remains a Queſtion, Whether it be beſt to have a little Nurſery for this Purpoſe, or to ſow them where they are to ſtand? This muſt be determin'd by the Soil where the Hedge is to be rais'd, for on that depends the Rule for the Choice. If the Ground be very poor and ſtony, it is beſt to raiſe them from Seed upon the Spot: if it be ſomewhat better, the beſt Method is to raiſe them in a little Nurſery, ſuch as has been before named, and to remove them at a proper Time from thence, to the Place where they are to remain.

But even in ſowing them upon the Spot, ſome Cautions are neceſſary. If the Soil be of an exceeding barren ſtony Kind, the Seeds will be burnt up before they take Root. In this Caſe, let the Place mark'd out for the Hedge be plow'd up deep, to ſee if any good Mould can be rais'd from below. If not, the Farmer muſt be at the Expence of having a ſmall Quantity of good Mould carried thither, and ſtrew'd upon the Place, that there may be ſome Defence for the Seeds. After this, they are to be ſown, as directed already, and a good and durable Fence of a dead Hedge is to be made on each Side, for it will be a conſiderable Time before the Plants grow up to be a Fence themſelves.

When the Ground is ſomewhat better, and will give Nouriſhment to a tranſplanted Set, the beſt Way is to raiſe them in a Nurſery, and keep them there till they are of the Thickneſs of one's Thumb, they are then to be removed to the Place, and carefully laid in, chuſing a mild and moiſt Seaſon. And for ſome Time after, they are to be ſhaded and watered, if the Seaſon be dry and ſultry to require it. They will thus take Root firmly: and if ſome of them ſeem to die, they muſt be cut off cloſe to the Ground, and they will uſually recover.

In this Caſe they require a dead Hedge on each Side, as well as when rais'd from Seed, for they are even thus a conſiderable Time before they come to their Strength, and while they are young and tender, the Sheep are very fond of feeding on them: when they are grown ſtronger, they need no Defence, for the Prickly-neſs of their Leaves is ſufficient.

Some when they plant a Holly Hedge, intermix white Thorn where the Soil will bear it. They plant four Sets of white Thorn, and one of Holly, and as the Holly grows, they pull up the Quick or white Thorn. The Uſe of the white Thorn is to raiſe the Fence the ſpeedier. When the Shoots of this are all pulled up, if the Holly ſtand too thin, the Way is to lay down Layers from it where the Vacancies are, and thus it may be thickened at Pleaſure.

When a Holly Hedge is raiſed by ſowing, the young Shoots are to be thin'd, when they are two or three Inches high, leaving the ſtraiteſt, ſtouteſt, and heartieſt: and after this they muſt be kept carefully weeded, and at Times it will be proper to ſtir and dig the Earth between them and the Hedges. This never fails to make them ſhoot out ſtronger immediately.

In this Manner may the Holly Hedge be rais'd with Certainty and Succeſs. Its Fault is the Slowneſs of the Growth, and the Care that is requir'd to be taken of it while young. But this is all that can be objected to it; for in every other Reſpect it exceeds all other Fences.

No Hedge whatſoever is ſo beautiful; none ſo ſtrong. When well grown, it appears as a Wall rather than a Hedge, and is altogether impenetrable by Cattle: and in this excellent Condition it remains a great many Years. We have obſerv'd already, that the Uſe of Hedges is not only for a Fence, but a Shelter for the Crop and Cattle. No Hedge whatſoever anſwers this Purpoſe equally to the Holly. An Eye cannot pierce, nor can the Wind blow through it. All within is defended as a Piece of Garden Ground, whoſe Fence is walling.

The Wood of the Holly when it grows to a certain Age, is alſo very valuable. The Cabinet Makers and Inlayers purchaſe it at a conſiderable Price: and of the Bark is made Birdlime. Theſe, added to the Value of it in the immediate Article of fencing, make it ſurprizing, that in a Country where in general it will thrive ſo well, it is ſo little planted. I hope theſe Obſervations, which are truly the Reſult of Experience, and confirmed by repeated Practice, will make it more common.

Where Thickneſs and Strength are required in a Fence, nothing anſwers the Purpoſe equally to the Holly, and it will grow to any moderate Height. The only Trouble is at firſt: and that is more with the tranſplanted Sets, than with the Shoots raiſed from Seed. Theſe laſt require little more Regard than the black Thorn, or any other: and their only Inconvenience is, the Time of waiting for their growing to uſe. As to the Sets, if the Seaſon prove unfriendly, they muſt be treated like Garden Plants, and be ſhaded and watered till they take Root, but after that they are no more troubleſome.

It is odd, that Holly which is thus fitter than almoſt any Thing elſe for a Field Hedge, and is one of the unfitteſt that can be conceived for a Garden, ſhould yet be in a manner in ENGLAND confined to the Garden, and neglected in the Field. But this is the Caſe; nor is there any Thing Cuſtom cannot do.

The very Thing which gives it its Preference in the Field, is the great Objection to it in a Garden. This is the Largeneſs of the Leaves. Theſe in the Field, fill and pleaſe the Eye, and thicken the Defence: they always appear beautiful here, becauſe they never are cut. In Gardens they muſt be cut; for there every Thing is to be kept in due Form; and the cutting of a Shrub with ſuch large Leaves as the Holly is improper, becauſe they look ſo ragged after it.

Fancy has taught People alſo to be very fond of the Variegations of the Holly; and great Pains are taken by buding and grafting to ſtreak and edge the Leaves with white and yellow; theſe are eſteem'd beautiful, but to a reaſonable Eye, they have only the Aſpect of Sicklineſs. They may be called pretty, but to him who has ſeen a free growing Holly in its own ſtrong and healthy green, with its Branches playing in wanton Luxuriance before the Wind, muſt think a ſtrip'd cut Holly, a very miſerable Improvement upon that beautiful Tree.

When the Holly Hedge is to be raiſed by Sets from the Nurſery, the greateſt Care imaginable muſt be taken, that the Seaſon is not dry or cold. The End of APRIL, in the Midſt of warm Showers, is the beſt Time of all. But it may be very well done toward the latter End of AUGUST, provided the Weather be cloudy, cool, and now and then ſhowery. In theſe Seaſons the Sets ſhoot out good Roots at once, and they ſeldom fail afterwards.

CHAP. XX.

Of the Elder Hedge.

WE have treated of the four principal, and moſt known, as well as moſt uſeful Shrubs for Fences; and we come here to the mentioning of one which at firſt Sight may ſeem of a very trifling and improper Kind: but there are Reaſons for prefering on certain Occaſions, Things that are in their general Uſe inferior. This we have ſhewn already, under the Article of black Thorn; which, though inferior to the white, may frequently be planted in its Stead to Advantage. In the ſame Manner, though the Elder be inferior to all that have been named, there are Occaſions that may render it very proper; nay, more proper than any of them. It is fit the Farmer ſhould know theſe, and the Nature, Uſe, and Value of this weak Shrub: that he may proportion his Choice to the Neceſſities of the Occaſion, and to the Value of the natural Produce.

Elder then is neither ſo ſtrong in its Branches, nor ſo cloſe in its Growth as the white Thorn, black Thorn, Furze, or Holly; nor is it prickly as they are: all theſe Defects render it inferior to them all for a Hedge; for theſe are the great and general Requiſites and Perfections of an Hedge Shrub: but there are ſome Occaſions on which this Toughneſs of Branches, this Cloſeneſs, and Pricklineſs are not requiſite; and in theſe the Elder may ſerve.

We are to remember alſo, that all theſe Shrubs ſo well fitted for hedging as they are, have their Inconveniencies; and Holly, the beſt of them all, particularly in the Slowneſs of its Growth. This, though in a leſs Degree, is alſo chargeable upon them all: but the Elder is the quickeſt of any in its ſhooting; and it will bear planting ſo large, and takes Root ſo eaſily, that it may be called an immediate Fence.

To this let us add, that the Flowers and Berries bear a Price at Market; and that the Wood of the old Stumps is valuable, and of ſure Sale to the Turners: and we ſhall find that

there

there is great Reaſon for naming the Elder among the Hedge Shrubs, for that it equals any of them in Value.

It has alſo another Benefit, that it is not ſo liable to be crop'd by Cattle, for they do not like the Taſte of its Leaves. Theſe are the particular Advantages of the Elder. It is true, that it is not proper for all Occaſions, nor will grow on all Soils: on the contrary, it will anſwer only particular Purpoſes, and will take Root only in tolerably good Ground: yet wherever it will, nothing anſwers better.

Elder makes an excellent Fence for Gardens, becauſe it is quick, ready, cheap, and affords ſo good Shade. In the ſame Manner where Fields are not liable to great Accidents; where the Banks are high and good, and the Cattle are uſed to be quiet in them, the ſame Shrub ſucceeds in the ſame Manner; for in the Conſideration of Shade and Shelter, ſcarce any Thing exceeds it.

When the Farmer has pitch'd upon a proper Place for a Hedge of this Kind, he needs not have the Trouble of raiſing the Plants from Seed, nor of laying them with that expenſive Toil and Regularity, as in the making up the Bank of Quick: the Elder will grow if any Piece of it be ſtuck into the Ground.

Let him cut a ſufficient Number of Elder Poles, eight or ten Foot in Length, and of the Thickneſs of a Child's Wriſt at the Bottom. Theſe he is to ſtick into the Earth of the Bank, not upright, but ſlanting; and when he has placed a Row at convenient Diſtances, ſlanting one Way, he is to ſet another Row in the Spaces between the firſt, ſlanting the other Way; by this croſs Direction, the Poles will form a Kind of chequer Work in Diamonds or Lozenges, and they may be ſecured, where neceſſary, by tying them at the Joints; and here and there faſtening them to a ſtrong Poſt.

No more than this is neceſſary, if the Soil be tolerably good: the Poles being thruſt ten Inches or a Foot deep into the Ground, will take Root; and almoſt immediately they will begin to ſhoot, and the Leaves by their Bigneſs and quick Growth, will preſently afford a perfect Shade and Shelter.

There is a great deal of Beauty to be obtain'd by the regular diſpoſing of theſe Poles. In the plain Way already mention'd, the Diamond Work is very pretty: but by cutting ſome in ſhorter Pieces, and a proper Care in diſpoſing and directing them in the Planting, they may be made into many of the Figures of thoſe Chinese Fences, which are ſo much admir'd in dead Work at this Time.

The beſt Seaſon for making an Elder Fence is in the Beginning of March: if the Weather prove dry, the Poles may be water'd half a dozen Times after they are ſtuck into the Ground, which will make them ſtrike Root ſo much the more readily. They will need no other Care but cutting to keep them within Bounds; for they are of ſo very free Growth, that unleſs this be done, they will ſoon exceed their intended Compaſs: nothing however cuts ſo eaſily; and no Shrub bears it better.

I have named the Advantages of an Elder Fence; 'tis fit therefore I name the Faults: for the Farmer, though he is to be told of Profits he may not be aware of, is not to be tempted into a Practice that has Inconveniencies, without being fairly told of them. When he ſees both Sides, he will be in a Condition to judge, which in any particular Circumſtance he is to take.

I have already mention'd the Weakneſs of the Elder, and its Want of Thorns and Prickles; for this Reaſon it is not to be truſted where Cattle can be tempted to break through, for it will not prevent them. As the Holly is the ſtrongeſt and moſt impenetrable of all Fences, this is the weakeſt and eaſieſt broke.

Another Objection to the Uſe of Elder for Fences is, that the Bottoms grow naked after a few Years, and nothing is ſeen but gaping Holes. The firſt is a material Objection; and the only Thing to be ſaid about it is, that the Elder is not fit in ſuch Caſes; but to this other, there is a ſhort Anſwer, and a very eaſy Remedy. As the Elder grows ſo readily, what can be ſo eaſy as to ſtop theſe Gaps by freſh Plants, as ſoon as they appear. Nothing more is neceſſary for this Purpoſe, than to cut off ſome ſtrait Sticks from the Trees where they can be ſpar'd, and plant them in the lower Part of the Bank, with their Tops juſt reaching to the naked Place. As the Planting of theſe Sticks is nothing more than thruſting them into the Ground, nothing can be ſo eaſy as this Practice, and nothing can be more certain, than that it will prove a ſucceſsful and certain Remedy.

Though the Flowers of the Elder, as well as the Berries, are uſeful in Medicine, yet they have ſo ſtrong and particular a Smell, that they are diſagreeable to many People; and are apt to give ſome Headachs. This is an Objection againſt the Elder, when there is any Thought of planting it very near a Houſe. But it is an Objection that reaches no farther. The very Wood, Leaves, and young Shoots of Elder, have all a diſagreeable Smell alſo, but this is not unwholeſome.

As the Berries of the common Kind of Elder are black when they are ripe; there are ſome Kinds which have them white, and others on which they continue always green, even when mellow; but theſe are trifling Variations, and little worth Regard. On the contrary, there is a Kind of Elder that differs from the others in the Leaves, and is worth the Planters Notice. I don't mean by this, thoſe idle and ſickly Variations of the Elder, with Leaves ſpotted with white, or ſtreaked with yellow, and kept in Gardens for their ſuppoſed Beauty: the Kind I mean here is, that Elder which has the Leaves finely cut into ſmall Diviſions. One meets with Trees of this here and there in moſt Counties of England: and I would adviſe the Farmer to plant a Parcel of theſe by way of Stock, whenever he ſhall find it convenient to have an Elder Fence; for this Kind of Elder has always more Branches than the common Sort, and when any Thing harden'd, they are ſtronger. The Leaves alſo are much more beautiful than the common Elder Leaves; and the Wood of this Kind is more ſolid than that of the other; and is prefer-

able to Box for many of the fine Works in which Elder is uſed by the Turners. People, while they are taken up with the Regard of a painted Leaf, do not attend to theſe real and uſeful Diſtinctions.

CHAP. XXI.

Of the Uſe of the Crab, Sallow, Bramble, and Alder in fencing.

WE have now gone through the Conſideration of the ſeveral Shrubs which are commonly uſed in Fencing, but there remain four others to be treated of, which, though ſeldom uſed alone for that Purpoſe, yet as they aſſiſt, or anſwer the ſame End on different Occaſions, ought to be named here.

As to the firſt of theſe the Crab, I have, in ſome few Places, ſeen entire Hedges of it; and they are very beautiful for the Regularity of their Growth. They give the Incloſure alſo the Look of a Garden when they are in Bloſſom; and have a pretty Effect when in Fruit. Neither are they without their Value, for the Wood is hard and ſerviceable; and from the Fruit is made Verjuice.

But with all theſe Advantages of Uſe and Beauty, I do not adviſe the making entire Hedges of it, for I have ſeen by Experience, that they are neither ſo good for Shelter or Fence. The Leaves of the Crab are indeed larger than thoſe of the white Thorn, but they are not nearly ſo numerous; and the ſame is to be obſerved of the Branches. Now the great Quantity of Branches and Leaves, is what gives the white Thorn the Preference above all other Shrubs for hedging.

When the Farmer ſhall chuſe whether it be from Faſhion or Whim, to have an entire Hedge of Crab, his Method is to be exactly the ſame as has been deſcribed for the white Thorn. Let him firſt ſet apart a Piece of poor Ground for a Nurſery. Let him there ſow the Seeds of the Crab, with the pulpy Part of the Fruit about them. And they will ſhoot quickly, and grow ſpeedily in good Shape.

When theſe Plants are of the Thickneſs of a Man's Thumb they are fit for Service: they muſt then be taken up, the Bank prepar'd, and the whole managed exactly as in the making a Quickſet Hedge of white Thorn. This is the Method to make an Hedge of Crabs alone, but it is what I would never adviſe the Farmer to do: the beſt Way of uſing this Shrub is, by mixing it with white Thorn in the Quickſet, when the Bank is made.

For this Purpoſe I would have the Farmer always, in his little Nurſery for his Hawthorn Sets, have ſome Crabs rais'd from the Seed, as already deſcrib'd. Let theſe be taken up, together with the white Thorn Sets, only in a ſmall Number; and laid in juſt as the Quickſets are. About one in every twelve, or fifteen Foot, will be very proper. They will thus grow up with the white Thorn; they will ſhew very beautifully in the Intermixture, when in Flower, and when in Fruit; and the ſame Uſe may be made of the Fruit for Verjuice; there will be a ſufficient Plenty of them for any moderate Uſe.

Some plant a Sallow among the Quickſet, at every fourteen Foot, in the Manner that the Crabs are here directed to be laid in: and in proper Soils this does well. It is of the Willow Kind, and therefore loves Moiſture, though it does not require ſo much as the common Willow. It is prudent therefore to plant this more plentifully in moiſt Meadow Fences, where, by its quick Growth, it is of conſiderable Advantages.

Brambles, or Blackberry Buſhes, are ſo far of the Nature of the Furze, that they will grow upon a very poor Soil: but it is not the Cuſtom to make Fences of them alone: nor are they fit for it, becauſe of the Length and Weakneſs of their Branches, which is ſuch that they cannot keep themſelves upright. They are of good Uſe planted on looſe Banks, to defend them from being over-run and trampled down by the Cattle. They alſo may be us'd to ſtop up Gaps in the Bottoms of Hedges, that with Age begin to grow bare in that Part. They may be rais'd with great Eaſe from the Seed; or Cuttings of them, will grow readily. The only Uſe they are fit for is, what has been juſt named, but that is not ſufficiently regarded: Nature very often ſupplies the Defects of Hedges with Brambles; and 'tis a Shame that Art does not imitate them in this as in many other eſſential Articles.

Laſt in this Diviſion of our Work, we come to name the Alder. This is a Water Shrub, and its Uſe in Fencing is of a very peculiar Kind. It defends the Sides of Meadows againſt being waſh'd away by ſwift running Waters. The Alder never grows ſo well as by the Sides of theſe Rivulets. The ſwift Streams of theſe frequently undermine their Banks, eſpecially at the Turnings: but the Roots of a good Alder are a ſure Defence.

There is ſcarce any Shrub whoſe Roots are ſo numerous or ſtout as thoſe of the Alder. And it is always ſending Suckers from the loweſt Roots; ſo that where there is ever ſo ſwift a Current, and ever ſo many Turnings follow one another, nothing more is needful to preſerve the Ground but to plant a ſufficient Number of Alders. In many Places alſo, where the Courſe of the River is ever ſo ſtrait, the Soil of the Meadow is ſo looſe and mellow, that it is continually waſhing in, and the Water is widening its Channel. Here the Alders are of the ſame Uſe: being planted along the ſtrait Bank, they preſerve it excellently.

CHAP. XXII.

Of the Bank Fence, with its Plantation.

IF our Intent were to recommend to the Farmer the Bank Fence alone, and naked, as it is uſed in ſome Places very commonly; we ſhould have inſerted the Rules for making it juſt after the ditching, leaving the Plantations of the Quicks to introduce that of Trees. But the Bank alone is a poor, raw, and ugly Fence, compared to the Bank with its Quick or Plantation: this is therefore its proper Place. The Manner of planting Quick has been ſhewn already: The Huſbandman has his little Nurſery of

Sets ready, and that not only of Quick or Hawthorn, but of the Crab, Sloe, and whatever other Shrub uſeful in fencing, is to be tranſplanted into its Place. We have now therefore only the making of the Bank to deſcribe; and the Manner of diſpoſing thoſe Sets which are ready rais'd, and of a fit Size.

The Bank is moſt proper, as an Incloſure, for Meadow and Paſture Grounds; and the Huſbandman ſhould firſt conſider the Nature of the Soil, before he attempts to raiſe it. Two Neceſſaries ſhould recommend it to him, the firſt, that it may be made cheap, the other, that it may flouriſh; and both theſe depend upon that ſingle Conſideration, the Soil.

An Earth that will cut eaſily and freely by the Spade, and is cover'd with a good thick freſh Turf, is the only one fit for this Purpoſe, nor let him ever have the leaſt Thought of raiſing it on any other. I ſpeak not of thoſe Banks of Clay or Dirt that are rais'd only by digging a Ditch, and piling up the Earth, and leaving it naked: but of the fine green Bank Fence which is uſed in ſome Counties, and deſerves to be uſed in all; which is beautiful and profitable; and remains firm, when once well made, for ever.

When the Huſbandman finds in his Meadow or Paſture Ground ſuch a Soil, ſo cover'd as juſt mentioned, let him ſet about the raiſing his Bank in the Beginning of the Spring, and at a Time when there have been moderate Rains. In very wet Seaſons the Earth of this Kind works untowardly, and in long dry Weather it is unfit; for it not only crumbles too much, but if the Bank be rais'd at ſuch a Seaſon, the Earth will ſwell and burſt, after the next Rains.

Having choſen then a proper Spot of Ground, and a fit Seaſon, the Work is to be executed in this Manner. In the Place where the Bank is to be rais'd, draw a couple of even Lines, at three Foot and an half Diſtance all the Way from one another. Then begin to dig up Turf in a Place cover'd with good ſtrong and freſh Graſs. Cut theſe Turfs a Span deep, of a long ſquare Form, and of ſuch Bigneſs as they may be moſt conveniently managed: as theſe are cut up let them be laid in two Rows, one along the Edge of each of the two Lines, with the graſſy Side outwards. They will lie thus in two Rows, with a Space between them.

A Foot diſtance from the outermoſt Row, not that which lies toward the Paſture, open a Ditch three Foot wide. Let it be dug ſloping, ſo that its Sides deſcend with a ſmall Slant, and carry it to ſuch a Depth as ſhall be neceſſary to ſupply a proper Quantity of Earth to make up the Bank, between the preſent and ſucceeding Rows of Turf.

The Earth which is dug up in this Ditch, is to be put in the vacant Space between the two Rows of Turf, juſt named, till it is brought to a Level with them. The Foundation of the Bank is thus laid, and it will be continued eaſily.

More Turf is now to be cut like the former, and a ſecond Row on each Side is to be laid on the former, very carefully; placing it even, but a little inwards; for the Bank is to be rais'd all the Way with a Slope, ſo as to be broadeſt at the Bottom, and ſomewhat narrower all the Way to the Top.

A ſecond double Row of Turf being thus laid, the Space left between them is to be fill'd up evenly with more Earth out of the Ditch: and the Surface well preſs'd down with the Spade: and left perfectly level, to receive the third Row of Turfs, and the Earth between.

No more Direction is needful for the raiſing of this Bank, than that the Work is to be continued in the ſame Manner, laying on more Rows of Turf on each Side, and filling up carefully the Space between with Earth; and continuing it ſlanting all the Way, till it is four Foot high, and at the Top its Breadth is two Foot and a half, one Foot being decreaſed in the Height.

The Space left between the two laſt, or top Rows of Turf, is not to be fill'd up ſo perfectly as that between the others; but the Top of the Bank is to be finiſh'd with a ſlight Hollow.

When the Bank is thus rais'd plant the Quickſets upon the Top. Let them be taken out of the Nurſery at a proper Size, and ſet a Foot deep on the Top of the Bank. They may be of any of the before-mentioned Kinds that bear tranſplanting, as Crab, white Thorn, or Sloe, but in general the white Thorn is beſt. It may be diverſified here and there with the Crab, or Sallow, but no Timber Trees, or large growing Fruit Trees are to be planted among it.

The Quick will flouriſh better in this than any other Plantation whatſoever. The Hollow at the Top of the Bank, which is ſtill to be preſerved in the Plantation, will detain the Rains, and ſend them down to the Roots of the Quick: and there is a fine Bank or Bed of Earth for them to grow in, which is thicker all the Way down, and has been juſt well ſtir'd and broken; ſo that it is in the fulleſt Perfection for ſupplying the young Growth with Nouriſhment.

When the Bank and its Plantation are thus finiſhed, a ſmall dead Hedge muſt be made on or near the Top, to keep the Sheep from runing up and nibbling the young Quick. Theſe Hedges need not be above fourteen Inches high, and no Matter how ſlight: for they will ſoon be needleſs; the Quick growing very faſt, and the Bank becoming every Day more and more firm, by the joining of the Graſs Roots from the ſeveral Turfs, ſo as to be in no Danget of Hurt from their Trampling, or indeed from any Accident whatſoever.

In the Autumn following let the Huſbandman go over the Hedge, Bank, and Quick, with his Eye, to repair what may be amiſs, it is very rarely that any Repair is wanted, but if there be the leaſt Damage it ſhould be ſupplied, for this is ſo beautiful a Fence that it is unpardonable not to keep it entire.

If there be any Defect in the Hedges, let them be ſupplied with ſome ſmall Buſhes of black Thorn: if any Turf in the Bank look decaying, or its Graſs become yellow, let it be ſupplied with a freſh one cut from the ſame Ground: and if any of the Quickſets have fail'd let them be replac'd with others, that all may be without Blemiſh.

It is proper to look over the Work, to ſee if any of theſe Accidents have happened: that if they have they may be ſupplied in Time, but it

very

very rarely happens that any do. In general, if the Fence have been made according to these Directions, it continues without Fault, and improves every Day, both in Strength and Beauty.

The Rains that fall about this Season of the Year, supply both the Turf and the Quick with Moisture; and while the former shoots briskly, the other continues in its Verdure. The fresh Roots of the Grass which are continually pushing every Way, join the several Turfs together in such a Manner, that they quickly form one Body, not a Joint being any where seen: and in a little Time the Roots of the white Thorn, spreading through the whole Substance of the Bank, bind all firmly together into one tight and solid Body, that nothing can injure it. The Grass continues to grow freely on the Slope of the Fence, and it is a Beauty: the crowning also of the Hawthorn, varied with the other Shrubs, which always look fresh and healthy, adds to the Grace of the whole, and makes it far exceed any other Fence whatsoever.

If the Ground be Pasture on both Sides the Fence; instead of a Ditch on the Outside of the Bank, the Earth on each Side may be lower'd with a Slope of two Foot deep. This will answer the Purpose of the Ditch, in supplying a Quantity of Earth to fill up the Spaces between the Rows of Turf, in making the Bank; and will answer two other Purposes. In the first Place, the Bank from four Foot will be made, by this Lowering of the Ground at its Foot, a Fence of six Foot high, beside the Hedge at the Top: and then no Ground will be lost for the Pasturage, because this hollowed Place will bear Grass like the rest; and so will the Sides of the Bank, which will, in good Seasons, be as green as any Part of the Inclosure.

If the Circumstances of the Place, or other Accidents, require the Fence to be higher, the Husbandman must begin with a broader Foundation; and must cut away the Ground more at the Foot, or dig a deeper Ditch for a Supply of Earth: no more Difference is necessary, for the Method of carrying up the Bank is exactly the same: and the higher and larger the Bank, the better the Quick will grow.

No Hedge whatsoever affords so fine a Shelter to the Growth, or to the Cattle, as this Bank with its Plantation. It must be consider'd indeed, that the Shrubs stand more exposed to the Winds on it, than on any other Plantation; and for this Reason they should not be left to grow too large. Some clip the Quick upon these Banks, which is a very good Method, for it at once thickens the Body, and keeps it in due Compass: and though, in general, the clipping of Trees be a very ridiculous Invention, it may be allowed, in this particular Case, with Use and Propriety.

CHAP. XXIII.

Of the Wall Fence, with its Plantation.

WITH respect to the Wall Fences of Fields, the same may be said as has been already observed of the Banks, that although they are frequently used singly and naked; yet they never have half their Beauty, or half their Value, when they are so imperfectly made. Their Plantation giving them their greatest Advantages and Superiority over the other Kinds.

In many Parts of England Stone is so common, and lies so ready, that it is the common Material for Fences: Walls, in the Way they make them in such Places, coming surprizingly cheap. We shall first speak of the most common Fences of this Kind; and afterwards of the better Kind.

The most rude and vulgar Fence of Stone, is the Wall they build about their Lands in Northamptonshire, and some other Counties, which, in the same Manner, yield that Sort of rough Stone us'd for this Purpose, near the Surface of the Earth; so that there is little Expence in digging, and in so many Places, that there is almost as little in carrying and laying it. In these Places they lay a Parcel of these rough Stones in the irregular flattish Shape in which they naturally rise in digging, upon one another, without Mortar, till they have rais'd what they call a Wall. This is so loose that in many Places you may see through it: and as where the Eye can pierce, the Wind very well may, these Walls are but a very indifferent Kind of Fence by way of Shelter; nor indeed do they deserve a much better Character in any other Respect, for they are so ill put together that they are frequently tumbling to Pieces. 'Tis true they are easily repaired again; for nothing is requir'd but to lay up the Stones in their Places; but when the Walls are made, as some are that I have seen in that and the adjoining Counties, the Work is endless.

The second Kind of Walls I shall mention, are such as are found upon the Grounds of more careful Husbandmen in the same Counties. These are made of the same rough and irregular Stones as the former, pil'd up on one another in the same Way, without Mortar; but then they are laid so much more carefully, that the Wind does not blow through them in so many Places; and the top Stones are laid in Clay by way of Mortar. Their own better Disposition in the Body, and this little strengthening at the Top makes these much superior to the former: they defend the Crop and the Cattle better, and they are not so continually tumbling down. The Difference of Labour in the building of these Walls is so trifling a Consideration, in respect of their Superiority over the others, that I have been surprized in looking over the Fences of those Counties, to see so many of the former, and so few of these. The one tumbling down every where, and the others tolerably firm.

A farther Improvement of these rough Walls I have seen in some few Places, which was by throwing in a Quantity of tough loamy Earth among the Stones, as they laid them in the Wall. This was a rough Imitation of laying the Stones in Mortar; and adds but a little to the Expence, while it encreases vastly the Goodness of the Fence. A Wall of this Kind, with the great Spaces filled up with Loam, and the Top tolerably laid in Clay, will stand a vast while, and answer the great Purposes of a Fence bet-

ter than either of the former, by many Degrees.

It may be natural enough to ſuppoſe, at firſt Sight, that the Wind blowing through the Holes in theſe rude Walls, would be no more Hurt to the Cattle that ſhelter under them, than that which comes through the Buſhes in a common Fence: but Experience ſhews it is much more miſchievous, and the Occaſion of it is plain enough in Reaſon. The Wind that blows through Buſhes comes broken and in a weak Manner; but that which iſſues in at a Hole in a Wall comes with a Draught and Current.

In the more northern Counties of England, where there is Plenty of a more regular flat Stone, they build their Fences of this Kind better in Proportion: in ſome Places, where the Stone naturally riſes in large flat and tolerably even Pieces, a Wall built of theſe without Mortar, and only top'd with ſome very ſmooth ones, laid in Clay or clayey Loam, ſtands a great while, and muſt be confeſs'd a good Fence for all the Purpoſes of Incloſure, Defence, and Shelter.

A much better Fence may, however, be made in any of theſe Places, even where the Stone is worſt of all, upon the Principle of the Bank Fence, deſcribed in the foregoing Chapter. This is what I ſhall recommend to the Huſbandman, where he has the proper Materials.

To this Purpoſe let him chuſe the eveneſt and moſt regular Stones he can conveniently meet with, for in thoſe Places they are often as ready at hand as ſuch as are worſe. The Preference is not ſo great in the making this Fence, as in the raiſing a ſingle Wall; but the evener the Stones the better, and it is worth while to be at ſome Care in every Circumſtance, about a Fence that is to be at once ſo beautiful and ſo laſting: for in both Reſpects this exceeds moſt others.

When he has provided himſelf with Stone, let him dig up the Ground a little Depth for a Foundation, and open a Pit, or Ditch, in ſome Place near, whence he can have a Supply of Earth as he ſhall want it, in carrying up the Wall. When thus prepared let him ſet to work.

He is to make, as it were, two Walls in one, laying the Stones one upon another, firſt two and then one between.

As the Wall is carried up, the Space between is to be fill'd up with the Earth dug out of the Foundation, or from the Ditch or Pit open'd for that Purpoſe. This brings all the Work into one Maſs, and adds Strength and Firmneſs.

The Stone Work is to be continued in this Manner, and fill'd up with the Earth to ſuch Heighth and Breadth as is neceſſary, according to the Circumſtances of the Place; and from Time to Time the Stones are to be beat in flat at the Sides, which gives the Work great Strength, as well as Regularity of Appearance.

When the Wall is thus carry'd to a proper Height, let there be Quickſets of any Kind planted upon it, in the ſame Manner as has been directed about the Bank Fence. Theſe will grow and flouriſh excellently, and there is ſomething in the Aſpect of a Wall thus crown'd with a thriving Hedge of Shrubs that is particularly pleaſing.

This is the fineſt, beſt, and moſt laſting of all the Stone Fences; nor is it a mere Propoſal from Fancy. Theſe Kinds of Walls are not uncommon in many Parts of the Weſt of England, and they there plant not only common Hedge Shrubs, but Aſh, Elm, and other Timber Trees upon them. To this indeed I object, becauſe the Force of the Winds upon ſuch Trees, when they are of any conſiderable Growth, is too much to be truſted, where the two Walls are to ſtand the Streſs of it: I have ſeen a very well made Fence of this Kind torn to Pieces for eighteen Foot length, by the blowing down of a middling Aſh that ſtood upon it: when the Trees are larger, the Danger is greater in proportion: nor is it either needful or proper to run the Hazard.

What I would adviſe is, to plant the Top of the Wall with white Thorn Sets, taken at a proper Age from the Nurſery; and for Variety, to add a Crab every twelve or fourteen Foot; for both the Flowers and the Fruit of that Shrub give a pretty Variety.

The Crab I have all along recommended to be intermixed in the Plantations of white Thorn Hedges; and its Beauty, which is ſome Recommendation, is not the only Advantage. Where that Shrub is left to itſelf, there is that Benefit of its pleaſing the Eye, but in whatſoever Fence it is uſed, it may be train'd up to anſwer other and better Purpoſes.

No Stock whatſoever is equal to the Crab for the grafting of Apples; and in Places where Cuſtom has eſtabliſhed the Property of theſe Fruits in Hedges, this ſhould be always the Uſe made of the Crab Shrub; for where People have been us'd to ſtrip Fruit Trees in Hedge Rows, they will not only take the Fruit, but break and tear down a great Part of the Hedge to get it.

In ſuch Places therefore the Crab is to be left to itſelf, and the Huſbandman muſt be content with pleaſing his Eye with its Bloſſoms, and with gathering its Fruit for Verjuice. In other Counties, where Fruit ſtands quietly in the Hedges, he is to order his Crab Trees in the following Manner.

Let him prune them up every Seaſon, till they are above the Reach of Cattle, and then let him engraft them with the moſt uſeful and valuable Kinds of Apples. The Way of doing this in the eaſieſt and ſureſt Manner, will be ſhewn hereafter, in its proper Place, when we come to treat of the Orchard: it is only named here as a Part of the Care of an Hedge.

Nor ſhould I omit to mention the Practice of a Gentleman in Devonshire, who on one of thoſe double Wall Fences, that had Earth between rais'd Apples inſtead of Crabs, at certain Diſtances between the white Thorn: it was a Matter of Curioſity more than Uſe; for the beſt Method for thoſe who intend to have Apples in their Hedges, is to raiſe Crab Stocks,

and graft them: but as it ſucceeded to his Wiſhes, I ſhall mention the Method.

Inſtead of Crab Seeds he ſowed the Kernels of ſome good Kinds of Apples in his Nurſery; and when he planted Quickſet upon any of his Walls, he placed one of theſe young Apple Trees at every twenty Foot. He took out an Apple Set of at leaſt three Years Growth more than the white Thorn Sets were, ſo that it had the Advantage of them in that Reſpect; and he planted theſe with a particular Care, and pruned them up with his own Hand, ſo as to give them all poſſible Advantages. The Conſequences of this was, that he was always able to ſhew Apples that the moſt experienced Cyderman did not know how to name. The Shoots from Seeds in all Vegetables, are thoſe that yield the Varieties; and by raiſing all theſe from Seed, and by the Benefit alſo of the peculiar Situation in which they were planted on theſe Wall Fences, he never fail'd to have here and there what they allowed to be a new Kind. Some of theſe he brought afterwards into his Orchard with Succeſs. This however was little more than Curioſity: for as to Uſe the Graft Kinds always bear ſooner; and in that Practice a Man is ſure of his Kind, whereas in this other Method all is Hazard.

The

The INTRODUCTION.

Of the Improvements made by Planting.

THE planting of Hedges, and of the Fruit and Timber Trees occaſionally interſperſed among the Shrubs compoſing them, leads us naturally to the raiſing and planting of Trees, and Shrubs in general. Our Buſineſs throughout this Work is to inform the Huſbandman how he may increaſe his Profits, and improve the Farm which yields them: and in nothing can that be aſſiſted, more than by judicious and orderly Plantations of Trees.

This will be the Subject of our preſent Fourth Book, and we ſhall begin with the raiſing, managing, and felling of Coppice, or, as it is commonly ſpoken, Copſe Wood, becauſe that is neareſt of kin to the Hedge Shrubs laſt treated of; and thence going from leſſer to greater, we ſhall advance to the Culture of Timber Trees.

There is no Step the Huſbandman can take in Planting, provided it be done with Diſcretion, that will not add to his yearly Income; or that will not be an enriching of the Land: and there is this farther Conſideration, that all he does in this Way gives alſo Pleaſure. It encreaſes the Beauty, as well as Value of the Ground; and his Eye ſhares the Advantage with his Pocket.

It is the peculiar Happineſs of theſe Plantations that all Soils will bear them. There are Lands too wet and too dry for Tillage: for there are ſome ſuch as it is impoſſible to improve. Theſe are the few really barren Lands of ENGLAND, yet on theſe Trees of one Kind or other will grow. They are to be ſuited properly to the Soil, and the Expoſure; and this done, they yearly increaſe in Value, and afford a Shelter and Defence to the Grounds, that before wanted it: thus extending their Influence beyond what riſes ſimply from their own Value.

In many Parts of NORFOLK, there are Valleys naturally rich and fertile, but lying at the Foot of ſandy Hills, they are overwhelmed with that barren Material by every Wind, and violent Shower. Of late they have in ſome Places begun to ſow upon the Sides of theſe Hills, FRENCH Furze. This grows ſo well, that once in three Years it is cut for Fuel, and ſells at a good Price; and all the Time it fixes the Surface, and preſerves the Meadows below. What pity that a Practice ſo doubly beneficial, ſhould not be univerſally follow'd.

As there are Shrubs appropriated to the drieſt Sand, ſo are there alſo to the moſt wet Side of a River. Theſe will be deſcrib'd in the ſucceeding Chapters; and it will be ſhewn, that no Piece of Ground whatſoever need be left unus'd, ſince ſome Tree or Shrub will grow on it; and the very meaneſt of them will yield very conſiderable Profit.

The Benefit of Plantations, whether of Shrubs or Trees, is not confin'd to this preſent or immediate Advantage: they improve the Land on which they grow; and the Planting a Copſe upon an unfruitful Piece of Ground, is an excellent Method of improving the Soil. This I have had Opportunity of ſeeing in my own Neighbourhood, where one of the barreneſt Spots in the Pariſh after yielding a great Profit from the Coppice Wood rais'd upon it, became a very good and fertile Field upon the ſtubbing up the Roots; and continues ſo to this Day.

Where Land is ſo indifferently fitted by Nature for Corn or Graſs, that it requires a great deal of Expence in manuring to produce a tolerable Crop, it is often better to plant it with Coppice Wood, for the annual Profits will be much greater, and the Expence in a manner nothing. There are alſo Pieces of Ground ſituated ſo unfortunately, that they are too remote from the Farm, or from the Sources of the Manure, and Tillage; theſe cannot be dreſs'd for Corn, but at a great Expence, becauſe of the Carriage of the Materials: here therefore is another Reaſon for planting; and the Succeſs is certain; and the Profits greater than any will believe who have not Experience.

The Land Owner is greatly concern'd in this. In how many Parts of this Kingdom are there Lands, that cannot be let for more than Five Shillings an Acre, and that from their Soil, Situation, or ſome other Accident, will not yield the Farmer any Profits at a larger Rent. How much muſt it be to the Advantage of the Owner in this Caſe, to plant them with Coppice Wood. At twelve Years Growth the Wood may very well be worth twenty Pound the Acre; and at a ſecond felling but ſeven Years afterwards as much: for the Roots being more eſtabliſh'd ſhoot faſter.

There is greater Security of the Profits alſo in this, than in the common Articles of Huſbandry, for Crops will fail ſometimes, and Stock will die. Here Nature does the whole Buſineſs, and is above the Reach of Accidents: nor is there any Difficulty in making, after a proper Growth, the Profits annual, and as regular as by any other Courſe. Suppoſe a Coppice of thirty Acres be planted and divided into ten Parts, one of theſe may be felled every Year: and by this Management every Year will yield three Acres of ten Years Growth.

A little Management in theſe Things is all. The Huſbandman who ſets out without it, will be perplexed with the leaſt Difficulties, and overturn'd in his Deſigns by the ſlighteſt Diſappointments: he who ſets out properly will overcome the greateſt.

The Huſbandman who ſhall ſee the Profits of this Practice, is not to ſuppoſe that becauſe barren Lands will bear Coppice Wood, only barren Lands are fit for it; nor is he to grudge the putting ſuch as are better, nay, even the beſt to this Service; or ſuppoſe the Price of the Rent will be a Drawback over-proportion'd to the Advantage: the Truth lies in juſt the contrary, for though bad Land will bear Wood; good Land will produce it much better, and the Growth will be quicker; ſo that the Benefit will be many Times over greater than the Coſt.

The better Land is that is planted, the larger will be the Profit. I have read with Surprize, of a Plantation upon a tolerably good Land, that at eleven Years Growth afforded Wood to the Amount of ſixty Pounds an Acre: but I have

have now ſeen it verified. A Piece of good Ground planted with flouriſhing Sets, will yield at eleven Years, Pole Wood, and Spar Wood, and ſome Quantity of ſmall Building Timber.

The raiſing of Coppice Wood and Timber Trees in Woods, is not the only Advantage to be made by planting. There is ſcarce any Place where ſome Tree or other may not be ſet, and there is none that does not bring its certain Advantage. Trees planted in odd waſte Places, Trees of Avenues, and thoſe in the Hedge Rows, ſet as before advis'd with the Quick, all yield a certain and a regular Profit. Every Man is a Gainer who ſets them.

The Time taken up in the Growth of Wood, is one great Objection, it requiring forty, fifty, or more Years to bring many of the Timber Trees to a Condition for felling to Advantage; but though ſlow, it is certain. Who would grudge to ſet a Plant that coſts him in a manner nothing, and that without requiring any Care or Trouble, will in fifty Years be worth four, five, or ſix Pounds. Who would grudge the Trouble of planting a Thouſand ſuch, which ſhould at the End of that Time be worth a little Fortune. What an eaſy Way of adding five or ſix Thouſand Pounds to an Eſtate: and where it is of any tolerable Extent, what is the Difficulty of adding inſtead of five or ſix, fifty or ſixty Thouſand Pounds this Way.

Indeed nobody grudges this Trouble, but all neglect it. Men do not look into theſe Things till a certain Period of Life; and then they are not to expect to live till the Time of reaping the Advantage. Perhaps not: but why ſhould they deny this Benefit to their Heirs! is there any Way ſo eaſy of raiſing Fortunes for younger Children. It is ſo eaſy and ſo certain of Succeſs, that 'tis a Crime to neglect it: and the Nation as well as Families ſuffer by the Fault.

But to thoſe who are ſo ſelfiſh, that they will not ſpeak a Word, or give an Order for their Heirs, the Plantation of Coppice Woods may be recommended as warmly as any other Practice whatſoever; becauſe they may reaſonably enough, at almoſt any Period of Life, expect Time to reap its Benefits: and theſe, although not ſo great as thoſe from Timber Trees, are enough to tempt the coldeſt Imagination, that is once inform'd what they truly are.

As to the Plantations for longer Growths, every Day gives us Inſtances of their Value. Things intended only for Ornaments to Eſtates, becoming in this Courſe of Time great Additions to them. How common is it to ſee the Trees of a long Avenue, which were planted only to pleaſe the Eye, of ſuch a Value, as warms the next Heir's Heart when he thinks of them. Others might as well have been planted, ſays he, in waſte Places, as theſe for Ornament; and he is ready to curſe his Parent who did not do it. Let him take Care to do for his Son, what would have been ſo acceptable to himſelf.

Between theſe Timber Trees and the Coppice Wood, may be mention'd another Kind, thoſe that are ſet for ſhrowding. The Aſh, and many other Kinds, ſerve very profitably for this Uſe, as ſhall be ſhewn at large hereafter. In general the Trees that are of quickeſt Growth are fitteſt for this Purpoſe; and for the reſt, they muſt be ſuited to the Soil, the Willow and Poplar for moiſt Places, and ſo the others as they naturally require.

Theſe are to be planted by Ditch Sides, in Hedge Rows, and on waſte Grounds: and they are to be ſhrowded according to their ſeveral Kinds, at ſix or eight Years Growth. After this they conſtantly bear a good Head, and the Shrowds increaſe for every following cutting. In the mean Time they are ſecure from Injuries of all Kinds, and need no Fences.

As the Shrowds are principally uſed for Fire Wood, the Profit ariſing from theſe Trees is greateſt where that is ſcarceſt; but there is no Place where it is not enough to make it very deſireable.

I have hinted before, that beſide the immediate and proper Value of Trees in Woods, Coppices, Hedges, or ſingle; they add to the Value of the Land about them, and this is ſeen every Day, and confirm'd by univerſal and continual Experience. Indeed there is no Wonder it ſhould be thus; for we ſee Hedges of vaſt Uſe by their Shade and Shelter. Woods, when they ſtand on the Edge of ſome Piece of Land, that would otherwiſe be expoſed to deſtructive Winds, muſt be of greater; becauſe being thicker, they are a more certain Defence. The ſingle Trees, and thoſe in Hedge Rows, afford Shelter for Cattle againſt the Winters Storms, and the Summers Heats; in either Plantation they afford the Huſbandman Timber for his neceſſary Occaſions; for the Repair of his Buildings, and his Implements, and for his Chimney. The Maſt bearing Trees yield Food for Swine; and, in fine, there is not one, the meaneſt of any Kind, that has not its ſecondary Uſes.

Finally, The Neceſſity of Wood where there are Iron Mines, and thoſe of other Metals, is ſufficiently known. Nothing is ſo eaſily rais'd as Wood, and no Soil but will bear it; why then will not thoſe who are ſo deeply intereſted in its Growth, raiſe it in ſuch Places.

BOOK IV. PART I.

Of Coppice, and other Small Wood.

CHAP. I.

Of raiſing a Coppice from Seed.

WE have in general propoſed the Diviſion of Plantations according to their Kinds, into Coppice Wood and Timber Trees, and are to treat of them ſeparately, becauſe they require in many Reſpects a diſtinct and different Management. We are to enter firſt on the Conſideration of the ſmaller, and after to advance to the larger Kind; our firſt Buſineſs therefore is to deliver Rules for the raiſing the Coppice Wood.

This may be done two Ways, by ſowing or by planting. We ſhall lay before the practical Huſbandman, theſe ſeveral Methods, with their Advantages and Diſadvantages; and direct him in his Choice, from the Reſult of Experience in both Kinds. In the preſent Chapter, we ſhall acquaint him with the Methods of raiſing the Coppice from Seed: in the next, by planting.

It has been obſerv'd already, that any Piece of Land, even the moſt barren, will bear Trees; and the Farmer will do well to plant on all ſuch Places; but he is not confin'd to them. He may take in a Piece of barren Ground; or he may uſe for this Purpoſe ſuch as has been tilled already; he need not grudge a tolerable Soil, nor think much of the Rent he pays, for if that be no more than its Worth, the Wood which is produced will not let him be a Loſer.

When he has fix'd upon his Ground, if it be to be taken from the Common, the firſt Thing he is to do is to encloſe it with a good Fence; for nothing is ſo liable to Accidents as a young Plantation, nor is there any Produce among which Cattle will do ſo much Harm.

If it be a Field that is incloſed already, he muſt thoroughly repair the Fences, that they may every Way keep out all Kinds of Cattle. This Expence of Incloſure may appear at firſt Sight a Diſadvantage; and the Preference may be given to the Plantation of Trees, for Shrowding or Pollards, which yield a great deal of ſmall Wood, and need no Incloſure, nor take up any Ground; but an Anſwer is given to this at once, by thoſe who have experienced both, which is, that the quick Growth of the Coppice Wood makes ample Amends for the Expence.

When the Ground intended for the Coppice is fenced in, let it be prepared by two or three deep and good Plowings, to refreſh and break the Mould thoroughly: or it will be very well worth while, where the Quantity is not too great, to dig it well up with a Spade. In this laſt Method the Way is to trench it throughout two Spit deep, and caſt the upper Part of the Soil undermoſt. This will prepare and break the Earth excellently: and it has been found by Experience, that in Ground thus prepared, the Trees ſhoot in a Manner greatly ſuperior to all that can be ſeen in any other Way of preparing the Earth for them.

Which ever of theſe Methods is taken, the Soil muſt be made very fine: if it be plow'd, it muſt be extreamly well harrow'd afterwards; if dug with the Spade, let the Rake come after, and the whole be laid as fine as the Beds in a Garden.

Where the Soil is tougher, it will require more working, and where more tender and mellow, leſs will do; ſo that there is no laying down particular Rules on this Head to ſuit every Occaſion. All that can properly be ſaid on the Matter is, that whatever be the Soil, it muſt be brought by frequent turning and breaking, to the Condition I have mention'd. If it be kindly, leſs Labour ſerves: if otherwiſe, more muſt be employ'd: but never let the Huſbandman ſlight over this Part of his Work, for all his future Succeſs will depend upon this thorough Preparation of the Ground.

If he have his Choice among different Kinds of Soil, he ſhould fix upon a good loamy Ground preferably to all others; and he ſhould chuſe that which is deep; for, though Trees ſhoot faſt and freely in a ſhallower Soil, they do not thrive upon it afterwards. However, ſuch is better for Coppice Wood than for Timber Trees, becauſe as they are for a longer and larger Growth, their Roots muſt pierce deeper.

The Reader who has conſider'd what has been written here already upon the Subject of Soils, will eaſily comprehend the Reaſon why a loamy one is here prefer'd to any other for the Growth of Trees in general. It is of a mix'd Nature between the ſandy and clayey, and therefore will agree with ſuch Trees as are ſuited to either of thoſe Kinds. None gives Paſſage to the Roots more freely; and yet, it has a Body that preſerves and faſtens them ſo, as to ſupport the Trees.

The Huſbandman being thus inform'd of the Nature, Dreſſing, and Fencing of the Soil for his Coppice; is now to conſider of the ſeveral Kinds of Seeds, and the Manner of ſowing them.

His Coppice is not to be entirely deſtitute of the Timber Kind, it being very proper to have ſome for Standards, but it is in general to conſiſt of ſuch as are of ſmaller Growth. Among theſe the principal, and thoſe of which Coppices are generally compoſed, are the Hazel, the wych Elm, the Birch, the flowering Aſh, the common Aſh, the Elder, the Hornbeam, the Maple, the Service, the Crab, the Cheſnut,

the Cherry, the white Thorn, and black Thorn, the Willow, and the Sallow.

Some of theſe delight in wet Soils, as the Willows and Alder, and others in dry or in middling Ground; this will be explain'd more at large hereafter, in treating of the ſeveral Kinds diſtinctly; but it is neceſſary to name it generally here, that the Planter may have it in his Mind, and direct himſelf accordingly.

If his Ground be in general wet, let him raiſe ſuch Kind of Coppice Trees on it as flouriſh beſt in the wet: if it be dry, let him conduct himſelf in the ſame Manner, ſelecting for it ſuch as love thoſe Situations: and if it be in part wet, and part dry, let him ſuit the Growth in the ſame Manner to each part, ſetting in thoſe Places which are wet, the Kinds that love Moiſture, and the others in thoſe which are dry. He is in every poſſible Reſpect to promote the free Growth of the Plantation, and nothing will do this more effectually, than a due ſuiting the Kind to the Soil.

When he has thus conſider'd his Ground, and determin'd what Kinds to raiſe upon the whole, or what particular ones upon the particular Parts of it; he muſt next ſeek for the Seed; and in this he is to be as careful as in any of the other Reſpects: or all his former Labour and Care will be thrown away. Let not any be frighted at the great Strictneſs and Conſideration of every Article in the preparing for raiſing of Copſe that is enjoin'd here. There is no great Difficulty in performing every Part in this nice and accurate Manner, and the Succeſs of the Plantation will always be proportion'd to it. In general where we ſee ſome thrive excellently, and others miſcarry, 'tis owing more to the Care that has been taken in the Preparation of the Ground, and Choice of the Kinds, and of the Seeds of each, than to any natural Excellence or Defect in the Place where they are rais'd.

To be ſure of the Goodneſs of the Seed, I would have the Huſbandman never buy it, but always ſave it himſelf. There may be a Thouſand Faults in bought Seed, which he will prevent in that he gathers; for his own Uſe becauſe he knows how much depends upon that Article.

As we have recommended no ſtrange or ſcarce Sorts of Trees for the Coppice, he may find enough of the ſeveral Kinds in his Neighbourhood, and may gather the Seeds himſelf.

In this let him take Care always to take them from a good, healthy, and flouriſhing Tree. Let him ſuffer the Seed to hang on this till it be thoroughly ripe, and then gather it by ſhaking the Boughs, and no other Way. And when he has thus got together a larger Quantity than he ſhall want, let him look it carefully over, and pick out of it for his Uſe only ſuch as is clean, ſound, firm, weighty and bright.

When the Seeds are thus pick'd, let them be put into large Garden Pots, with ſome Sand, and ſet by in a tolerably dry Place for the Winter. They might be ſown in Autumn as Nature ſcatters them, but then they would be in Danger of being eaten into by Inſects, or devour'd by Field Mice, and other Vermin. Nature intends the feeding theſe Creatures with the Seeds of Trees, as well as the raiſing a Supply of each Kind; and it is therefore they fall naturally at that Seaſon: but the Huſbandman in this Inſtance has nothing in view but the raiſing that Supply, therefore he will do well to avoid the Danger of their being eaten.

All is now got ready for the Sowing: the Seeds have been preſerv'd during the Winter, and the Ground ſo well work'd, that it is ready to receive them. The Spring is come, and the Huſbandman muſt get to his Work. Let him take out his Seed, and ſpread it carefully.

I would adviſe him by all Means to do this with his own Hand, going over the Ground with a judicious Eye, and ſcattering the Seed equally, and ſparingly. After this let it be well cover'd, and then Nature is to be left to herſelf.

There is a great deal of Difference in the Time of ſhooting of the ſeveral Kinds. Some ſhewing themſelves quickly, others not till after ſeveral Months, and ſome not till the Spring following. This has been obſerv'd already, and will be treated alſo more particularly hereafter, under the diſtinct Heads, where we ſhall mention the ſeveral Species.

When the earlieſt ſhooting Kinds have begun to ſhew themſelves, if there be any Quantity of Weeds riſing among them, let them be carefully rooted up, and if the Seaſon prove very dry after the deſtroying the Weeds, give the whole Ground, if it can conveniently be done, a little Water. The Earth having been diſturb'd by rooting up the Weeds, will receive this the more readily, and it is ſurprizing to ſee the Effect it takes on the young Plant.

After this the Huſbandman is to wait Natures Courſe for the Shooting of the ſeveral later Kinds, keeping his Fences in perfect Repair, and have an Eye frequently on the Plantation, to keep off all Miſchief, for nothing is ſo eaſily hurt as a Tree in its firſt Shoot.

When Winter comes on, let him order ſome black Thorn Buſhes to be ſpread lightly, and carefully, over the young Plantation; and upon theſe ſcatter a little Straw where the Ground is moſt expos'd to the Winds. This will break the Force of thoſe nipping Blaſts, which are ſo fatal to young Roots of Trees, and preſerve them from all other Miſchief.

The Summer following let the Plantation be kept clear of Weeds; and as the Winter comes on let there be a few black Thorn Buſhes ſcatter'd over the Ground, but more lightly than at firſt, to defend the young Shoots of thoſe Seeds which have not appear'd till the preceeding Spring, that they may be in like Manner defended their firſt Winter.

The Summer ſucceeding this, let the Huſbandman carefully go over the whole Ground, after a thorough weeding, and let him draw ſome of the Shoots where they have riſen too thick, and plant them in Places where they have riſen thinner. This is his Time for thinning and regulating his Plantation; and after this having once more look'd carefully to his Fences, he may leave all to the Courſe of Nature: not doubting but that he will have a Growth of Coppice Wood in every Reſpect as much exceed-

ceeding that of his Neighbours, as the Care he has taken in theſe ſeveral Articles has been more.

I am ſenſible that in the whole Courſe of ordering this Coppice Ground, I have given the Huſbandman Directions to employ a great deal more Trouble than is generally allow'd to this Article of his Buſineſs: but I am alſo ſure from Experience, that he will be well paid for every Part of it, in the ſpeedy Growth, and Quantity of the Wood.

Some have a Way of raiſing a Coppice from Seed, by ſowing the Seeds of their ſeveral Kinds of Shrubs with their Corn, upon a Piece of Land they intend to lay up for this Purpoſe. I have read Books in which this is recommended greatly; and I have ſeen it try'd, but the Event has not anſwer'd to the Promiſes. The young Shoots have always ſuffer'd greatly by being trod upon in the getting in the Harveſt, and though the Stubble being left ſtanding, affords ſome Shelter for them the following Winter, it is but very poor in Compariſon of that regular Method I have here propoſed.

There can be no Objection rais'd againſt this Method, of which I have ſpoken ſo largely, but it's Expence: and this, if it were great, would be anſwer'd by the Increaſe; but in Reality it is not. The Care requir'd of the Maſter of the Plantation, is greater than the Charge; for his own Eye muſt be over all. As to the reſt, a little Money will go a great Way; and what ſeems much in the directing, is little in the working.

CHAP. II.

Of raiſing a Coppice by planting Sets.

WE have ſhewn in the preceeding Chapter, a Method of raiſing a Coppice with Certainty and Succeſs from Seed; in this we are to propoſe as candidly the other Way of doing it by Sets; and it will become us to be as impartial in the Account of the Advantages either Way as poſſible.

But to prevent an Error at the ſetting out, it will be proper to name one natural Objection againſt the Way of doing it from Seed, which is the Loſs of Time. The Sets, or young Trees, coſting little, and being advanced ſome Years Growth when put into the Ground. This is rather a natural Objection than a judicious one; for, though it hold true of ſome Trees and Shrubs, it does not of others. There are ſome that will take at once, and ſhoot ſtrongly upon the Removal; others will be ſo much the more ſlow for it, that it has been of a ſeedling Tree, and one tranſplanted, that the former has in a few Years overtaken the latter, though it was of ſeven or eight Years Growth; and has continued growing ſtronger for many Years after, though the Soil, Situation, and Expoſure, were the ſame to both, and all other Advantages equal. Mr. Worlidge, an Author of great Veracity, aſſerts from his own Knowledge, that a Walnut ſet into the Ground, ſhall overtake a Tree of ten Years Growth planted at the ſame Inſtant.

One Thing more is to be obſerv'd againſt the Way by planting, which is, that as it will be prudent to have ſome Timber Trees in a Coppice, theſe will do much beſt from Seed, becauſe the Shoot is always ſtraiter, and grows evener, and more regular, when ſown in the Place, than when brought in by tranſplanting: and this in Timber Trees is a vaſt Article, their Value being, when grown, in a great Meaſure proportion to it.

Upon the whole it is to be allow'd alſo on the other Hand, that Shrubs, and the leſſer Trees, bear tranſplanting better than thoſe which grow to a greater Height: and one everlaſting Rule muſt be, that the Huſbandman either raiſe them himſelf upon a poor Piece of Ground; or take Care it be a poor Piece, from whence he takes them if bought. This being the Caſe, they will, upon being removed into his own better Land, ſhoot more freely; whereas if his own Soil be poor, and that of the Nurſery have been better, they will make but a very ſlow, and bad Progreſs, as has been named already, on other the like Occaſions.

After theſe general Obſervations, we ſhall come to the Method of raiſing the Coppice by Plantation; in which the Huſbandman is firſt to go through all the Care of raiſing the Shrubs in a Nurſery, or elſe to be at the Expence of purchaſing them; and the greater Hazard of their thriving. There are many Reaſons why he ſhould raiſe them himſelf; we ſhall therefore ſuppoſe he intends that, and begin from the firſt Article.

He muſt firſt then ſelect a Piece of Ground for a Nurſery; and in this he muſt be very careful; for on his proper Choice of this, depends a great Part of his Succeſs in all that follows. He is in his Choice to have regard to its Soil, and its Situation and Expoſure.

In Soil it muſt be very poor, for the Reaſons given already, that the Shoots may flouriſh when removed to the other Ground. There is ſcarce any Ground in which the Seeds of the ſeveral Trees and Shrubs will not ſhoot; and all that is requir'd of this Place is, that it be ſuch as will give them Power to make the firſt Shoot, and ſupport it to a little Heighth. I ſay a little, becauſe I am for the Farmer's taking up his Sets earlier than is uſually done; being certain that the younger they are tranſplanted, the better they will thrive; and that the Time thus loſt in other Uſes on the Land, will be well repaid by their expeditious Growth. This Loſs of Time, and Uſe of the Land, is the great Reaſon of the Preference given by many to planting, inſtead of ſowing the Ground for a Coppice. But Experience has ſhewn us, that any Loſs ſo ſuſtain'd, is repaid manyfold.

In Situation, this Spot deſign'd for a Nurſery, muſt be defended from the North and Weſt, and open to the South Eaſt. It muſt be well fenced: for one Breach may deſtroy the Labour of ſeveral Years, and it will be beſt if it lie dry. This is an Advantage of the ſame Kind, with that which is drawn from the Poorneſs of the Land: for the Trees tranſplanted from a dry

to

to a moſt Soil will always ſucceed; whereas, if removed from a moiſt to a dry they are very apt to miſcarry.

Such a Piece of Ground being choſen and fenced; let it be well turn'd up by the Plow or Spade, in the Beginning of Winter. Let it be turn'd again early in the Spring, and perfectly clear'd from Weeds; and then let the Seeds be ſown in it. Theſe having been gather'd, examin'd, and pick'd by the Farmer's own Hand, in the Manner before deſcribed, for ſowing the Coppice.

The beſt Manner of ſowing is this. Let all the Seeds be kept ſeparate; and let the Ground thus prepared be cut up with Trenches or Furrows four Inches deep, drawn at two Foot diſtance quite along or acroſs it, and in theſe Furrows let the Seeds be ſown, ſcattering them lightly in; and ſowing only one Kind in one Furrow. When they are in let the Ground be drawn over them with a Rake, and then the whole left to Nature, only taking Care to keep the Place clear from Weeds.

There are two Sorts of Weeds in particular that are to be guarded againſt in a Nurſery, theſe are the common Dock, and the common Couch Graſs. The Dock roots itſelf ſo deeply that it cannot be torn up afterwards, without diſturbing ſome of the young Shoots; and the Couch Graſs ſpreads ſo by running under the Ground, that it will entangle itſelf with the young Roots, and rob them of their Nouriſhment; and will be impoſſible to be rooted up without tearing them up with it.

This Method of ſowing by ſprinkling the Seeds in a Trench, or Furrow, is beſt for thoſe Shrubs which have ſmall Seeds; but for ſuch as are larger, as it will often be proper to have ſome of theſe, the beſt Method is to ſet them with more Exactneſs and Regularity. Thus Acorns and Cheſnuts, for the raiſing their ſeveral Trees, are beſt ſet in Rows by themſelves by a Line. But with reſpect to the Oak in particular, I ſhould always be for planting the Acorn in the Ground where it is to ſtand, for the Reaſons before-mentioned, the regular Growth of that Tree being a great Article in its Value.

The Nurſery being thus ſown is to be watch'd juſt in the ſame Manner as the young Coppice, when rais'd from Seed; and particular Care muſt, in either Caſe, be taken, to keep out Hares and Rabbits; for they will get in where there is not a Breach for Cattle, and they will eat up a whole Plantation to the Ground, when it is very young; and from their gnawing it never well recovers; and when the Shoots are of a larger Growth they will, in hard Winters, eat off their Bark, which is as deſtructive. The Care therefore of this Article extends to the Coppice, as well as the Nurſery. The particular Methods of warding againſt this Miſchief will be laid down hereafter, in its proper Place; where all the Accidents to which Trees are liable, will be treated of together.

The Seeds of the Nurſery having thus ſhot, and the Shoots having been thus preſerved in their tender State, from Weather and other Accidents; when they are grown to an Age to remove for the planting of the Copſe, let the Ground laid out for it be opened in good, deep, and wide Trenches, at twelve Foot diſtance. Let this be done in the latter End of Autumn; and let the young Sets be carefully removed out of the Nurſery, and, with all Exactneſs and Regularity, ſet in theſe Trenches.

In the Nurſery the Seeds of the ſame Kind of Shrub were always ſown in the ſame Furrow, but in the tranſplanting them let the different Kinds follow one another in the ſame Row, at moderate Diſtances. Thus the Coppice will be planted in the ſame Variety with that which is rais'd from Seed, and the Trees will not only look but thrive the better.

There is this Advantage in planting the young Trees in Rows ſo diſtant from one another, that the Huſbandman may make uſe of the Ground between the Rows for any other Growth, till the Trees are of ſome Height; and this tilling between, far from hurting the young Trees, will aſſiſt their Growth. Then the Coppice will grow afterwards with a beautiful Regularity, being all laid out into natural Walks and Alleys. I ſhould not name this as an Article worthy the Huſbandman's Conſideration, if it had in any thing interfered with his Profits; but it here agrees with them in every Article, for theſe vacant Walks will, in the felling Time, give the Workmen room to cut and finiſh up their Work well; and they will alſo give good and free Room for the Carts to come for the carrying off the Produce: and at the ſame Time Experience ſhews, that the Quantity of Wood produced in the ſame Number of Years, will be greater in a Coppice that has been planted in theſe diſtant Rows, than in one where the Trees have been ſet in the uſual thick and confuſed Manner.

CHAP. III.

Of the managing and ordering a Coppice in its Growth.

I Have laid before the practical Huſbandman the two Methods of raiſing his Coppice, at once from the Seed, or by the Aſſiſtance of a Nurſery, that he may take his Choice, according to his own Pleaſure, to the Uſes he can make of his Ground while the Shoots are raiſing in the Nurſery, or to other Circumſtances, for theſe may preſcribe a different Conduct on different Occaſions.

I ſhall not preſume to lay down any general and abſolute Rule in this Caſe. All I ſhall ſay is, that what I have ſeen by Experience in the Country where I live, would lead me to prefer the Method by Seed, where all other Circumſtances were indifferent either Way; but I would not advance upon this limited Knowledge, that the ſame Practice is to be prefer'd every where.

We have ſuppos'd the Coppice now rais'd by one or other of theſe Methods; and the Trees beginning to acquire ſome Strength. The Planters Care, though it be leſſen'd at this Time, does not abſolutely end there; he is to ſee that his Coppice be duly ſupplied with young Trees and Shrubs in all Parts; not too full in one Place and vacant in another.

To this End he is to go over it the Year after all was left ſettled, whether by the Seedlings or tranſplanted Shoots, and in general this will be the Difference, that in a Coppice rais'd by ſowing his Buſineſs will be to thin the Ground; and in that rais'd by planting to thicken it in ſome Places.

In this as well as the firſt thinning of the Coppice rais'd by ſowing, I would have the Planter keep in his Mind the Advantages ariſing from the planting the Shoots in the other Way in thoſe diſtant Rows, as has been directed under that Head. This is a Method which gives a conſiderable Advantage to a planted Coppice over the ſown; but it is an Advantage that may in a great Meaſure, though not perfectly, be given to the ſown Coppice in the Manner of thinning.

In the ſown Coppice Preference muſt be given in the taking up ſuperfluous Shoots, to the ſtrongeſt and beſt growing; but ſo far as may be let the thinning be ſo conducted as to leave the ſtanding Shoots in diſtant Rows. Theſe will never be ſo regular as when the Coppice is planted in Trenches dug by a Line, but the nearer it approaches to that the better.

It muſt be own'd alſo, that in Coppices rais'd by ſowing, not only the ſeveral firſt Years Uſe of the Ground is loſt, but alſo the Advantage of tilling and employing the Earth between the Rows afterwards, which tilling, as before obſerved, is ſerviceable alſo to the Trees; but where I have ſeen the Experiments made, the Method by Seed, as I have ſaid already, in ſpite of all this had the Advantage.

Upon the fulleſt Conſideration of all theſe Particulars which I have now, in their due Courſe, laid before the Huſbandman, perhaps it will appear in general, that when rich and valuable Land is to be laid up for Wood, the Method by planting is to be prefer'd; and when poor Ground of ſmall Price or Value is to be employed for this Purpoſe, then the beſt Method is by ſowing. But in this, as in the former Inſtances, the Rule is not to be delivered as univerſal, but the Owner, or Farmer, is to weigh all the Circumſtances together, and then determine. They have been all laid here ſo particularly before him, that he may have them in his Eye together, and ſet out in this profitable Article of his Profeſſion, in the moſt advantageous Manner.

We have directed him in the going over his riſing Coppice for the laſt Time, if it have been rais'd by ſowing, to thin it, by taking up ſuch Shoots as ſhall be found ill-faſhion'd, or ſuperfluous, in ſuch a Manner as added to the firſt thinning, ſhall diſpoſe the Shrubs, though rais'd at Random from ſcattered Seed, into the Appearance of ſomething like Order and Regularity.

On the other hand, when he makes this Viſit to his Coppice rais'd by planting, he will find it is thickening that it wants; and this is as eaſily done as the other. The Shoots were planted here in ſuch Number only as it was fit they ſhould ſtand; and though this has been done ever ſo well, ſome will have fail'd: the Places of theſe muſt be ſupplied; and whereas ſome others will be found to grow very irregularly and ill, it will be beſt to take them up and put others in their Stead.

This is the laſt Time of going over the Plantation with this View, ſo that if any of them are found to grow ill afterwards, the beſt Way is to cut them off ſlanting near the Ground, and leave them to make a new Shoot; which, the Root having now great Heart, will be very ſtrong.

But in this Article of thickening a Coppice for the laſt Time, in order to its full Growth, we are not to omit that there are other Methods, and thoſe very eaſy and familiar, beſide that of taking up a bad Shoot, and planting a freſh one in its Stead; or ſetting ſuch in accidental Vacancies.

In the firſt Place, there are ſeveral Kinds of Trees and Shrubs that will grow very well from Stakes or Cuttings; and theſe will ſucceed no where ſo well as in a Coppice of ſome Years Growth, becauſe they are ſhaded, and the Ground is kept damp about them as if watered.

The Trees which are to be planted thus by Sets, are more numerous than commonly imagin'd, the Willow, Sallow, Oſier, Alder, Aſpen, and black and white Poplar and Elder, may all be thus rais'd, and the Time for planting the Sets is early in Spring. Theſe are of excellent Service for the thickening the Coppice, in Parts where the Ground is damp. This Wetneſs which has cauſed the other Plantation to fail, will make theſe thrive, for they are the proper Trees for it, and will never fail. It will be uſeful to go over the Coppice, whether rais'd by ſowing or planting, in this Manner in Spring, when it is of a due Growth; and thus to add to it, in the proper Places, theſe Kinds which love a watery Soil, and which will not only thicken it as to Number, but advance beyond all others in thoſe Parts of the Ground.

As Spring is the Time of adding theſe Trees, in this particular and eaſy Manner to the Coppice, the Seaſon for ſupplying its Deficiencies with the others, if introduced from the Nurſery, is in OCTOBER or NOVEMBER; they are to be choſen of a proper Growth; and to be taken up juſt after the Leaves are fallen. In the removing theſe, as they are ſomewhat larger than thoſe firſt planted, ſome more Care is to be taken. They are to be rais'd up with as much of their own Earth about them as can be preſerved, and only the tap Root, or large downright Root, is to be ſhorten'd: a large Hole is to be open'd for their Reception; and the Roots are to be carefully and evenly ſpread in it, and cover'd with light Mould. The whole being fill'd up, the Plant is to be watered, and ſo left to grow.

As this Method of tranſplanting into the Coppice is much more troubleſome than that of raiſing the Willows, and other Trees juſt mentioned, by Sets; there is another middle Practice between them, which may be us'd very advantageouſly for the thickening of a Coppice: and this is by what is call'd among Gardiners, laying of the Branches.

To this Purpoſe, when the Huſbandman ſees a vacant Place that wants to be thickened, let him pitch upon a good Branch of one of the neareſt Trees on each Side; and giving each a Chop half through, or more, as has been before obſerved on the plaſhing of Hedges, let him

bring it down to the Ground; and opening the Earth a little, lay in the Branch, ſtaking it down with two or three Pegs, and then cover it with the Mould that was thrown out.

Each of theſe Branches, thus laid, will produce a great Number of Suckers, which will grow freely enough; and the vacant Place will thus become, perhaps, one of the thickeſt Spots of the whole Coppice, in leſs Time than could be imagin'd.

The laſt Time for laying of theſe Branches is in the Beginning of the Spring, juſt when the Sap is riſing freely, and the Buds are going to break out on the Twigs. If the Earth thrown out of the Trench, that was made for laying it, do not cover it thoroughly, there ſhould be more added till a little Hill be rais'd all along. Where the Branch is carried: this will forward the ſtriking of Roots downwards, and Shoots upwards; and the Quantity and quick Growth of the young Plants, will ſurprize thoſe not uſed to theſe Aſſiſtances of Nature.

If the Coppice be too thin in many Places, where the Branches from the neighbouring Trees cannot be laid to thicken it; let ſeveral Branches of ſome other proper Kinds be laid in their Place, in the Manner juſt directed for a Supply of young Trees, if the Nurſery do not afford a competent Number for that Purpoſe. Theſe will ſend up each its proper Quantity of Shoots, and they may afterwards be removed to Places where they are wanted with little Trouble.

Many Trees are propagated better this Way than any other, in particular the Lime, the Birch, and Horſe Cheſnut; and the Elm very well. Theſe young Sets are to be removed early in Spring, and once water'd, and they will grow without any farther Trouble.

The Sets of Willow, Poplar, and the like Kinds, which we have order'd to be inſerted early in Spring in their proper Places in the Coppice, are to be cut only one Way, at the End that goes into the Ground. Experience ſhews that they take the more certainly for this little Circumſtance.

Finally, to give the laſt Article in the Management of young Coppices, we are to mention the cutting them down at a certain Growth: not for their Wood, but to increaſe the Quantity afterwards.

Some deliver this as a neceſſary and univerſal Practice; and in ſome Places it is univerſally done: but this we do not recommend, though, in part, ſuch a Practice be very uſeful.

It is founded on this, that from the main Shoot when cut off, there will riſe a Number of others: this is a plain Truth; but Experience does not therefore always ſupport the Practice. When this is done, it is to be at two Years Growth, if the Coppice have been rais'd by planting, and at four Years if it have been rais'd from Seed. The Shoots are to be cut off within three Inches of the Ground, and there will riſe from them many new Shoots, which the Root will puſh up very vigorouſly, and which will ſoon make ſo many good Poles.

There may be Places where it will be neceſſary, or at leaſt proper, to cut down the whole Growth at that Time in this Manner. Particularly when the Soil is very poor, and the Coppice having advanced ſo far, is ſeen not to proſper. In this Caſe the cutting down the whole within two or three Inches of the Ground, will give Strength to the Roots, and they will ſhoot up vigorouſly from all the Stems: but although particular Circumſtances, and eſpecially bad ones, may ſometimes render this proper, it is not to be ſet down therefore as univerſally neceſſary.

Some Time is plainly loſt by it; and in Places where the Growth ſucceeds well, 'tis evidently better to let it wholly alone than to cut it up. 'Tis better in this Caſe to take an earlier felling, as for Inſtance, at eleven Years Growth; and then to expect the Growth of theſe numerous Shoots, which will riſe ſo quick from the Roots now ſo confirmed and ſtrengthened, that in ſeven or eight Years, there will be another felling ready, richer than the firſt.

But to ſpeak from Experience, and to favour real Advantage more than any particular Scheme, it will be beſt to moderate the Practice; and I would have every Huſbandman in part follow it, whatſoever be the Soil and Condition of the Growth, tho' very rarely do it entirely.

Thus at the third Year, if the Coppice have been raiſed by planting; or in the fifth, if from Seed; I would have him go through it for the laſt Time with a careful Eye, making good all Deficiencies, and retrenching all Superfluities: and I would have him now take a Labourer with him, with a good ſharp Bill in his Hand. Let him examine every young Tree in the Coppice, and let him leave all ſuch as grow proſperouſly and regularly to ſtand as they are, but let him ſee every one that grows irregularly and ill, or that ſeems not to thrive like the reſt, cut down in this Manner within three Inches of the Ground, by one ſlanting Stroke of the Bill. This Practice will give Strength to ſuch Roots as want it, by taking off for the preſent the Shoot that was too much for them to feed; and it will leave the reſt to continue in that proſperous Condition wherein he finds them. This is the Practice of Reaſon; and this the Method in which the moderate and judicious Huſbandman will uſe all thoſe Inſtructions which are given by People too warm in the Purſuits of their particular Notions, to give Way to a due Conſideration of their Intereſt.

CHAP. IV.

Of the Felling of Coppices.

WE have now brought the Coppice to a Time and Condition, in which it wants no farther Aſſiſtance from the Huſbandman; he is only to ſee that the Fences keep ſound in every Part, and leave all to Nature. The Trees are now too ſtrong to be hurt by Weeds; on the contrary, they will ſuffer none to live among them; except ſome few of a particular Kind, as Fern about their Roots, and Sanicle, Betony, and ſome other ſuch under their Shade, which do no Harm, and will not live elſewhere. The

Husbandman is to give himself no more Trouble on this Head, but wait with Patience till the Coppice is fit for felling.

We meet with very punctual Directions on this Head in Books; and every Woodman to whom the Husbandman shall speak on the Subject, will dictate to him as positively: but Experience is more cautious; and following that Guide alone, we shall tell him that no exact Direction can be given. The Writer delivers imperfectly, what he has heard partially; and the Woodman forms his Judgment upon what he has seen in two or three particular Places, and thinks all Nature is to follow that Rule.

Experience shews, that in different Places the Growth of a Coppice is very different, according to the Soil, Situation, Degree of Moisture in the Ground; and many other Accidents: some very obvious, others not to be discern'd by the most curious and penetrating Eye. The Time of felling the Coppice is to be regulated according to this: for 'tis not its being of such an Age from the Sowing or Plantation, but its being in such a Condition of Growth that renders it fit to cut.

All that can be deliver'd with Certainty on this Head is, that the earliest Time at which a Coppice should be cut, in whatever Manner it has been rais'd, is the eleventh Year. It is only in favourable Soils and Situations, that it is fit to be felled so soon; and in others, from this Time the Husbandman must Year by Year watch its Growth, to see when it is in a Condition for cutting down to his Advantage.

Twelve or fifteen Years is a common Age for felling; and sometimes there is a Necessity of letting the Wood stand longer. But this is to be understood only of the first fall: for the Roots are then so establish'd, that a much smaller Time does for a new Growth.

It is a very good Practice in many Circumstances, to fell the Coppice in Parcels, as has been hinted already. For Instance, Let the Owner begin at twelve Years Growth, and fell one eighth Part of his Coppice: the next Year let him fell another eighth Part, and so on every Year one eighth, to the last. The last Years felling will then be of twenty Years Growth; and he will find it will very well pay for the Length of its standing.

Every succeeding Year's felling will be larger and larger than the last; and the Difference between the Growth of twenty Years, and that of twelve, greater than will easily be imagin'd.

This is the Way of making the Coppice yield a regular annual Income; for by that Time he has felled the last eighth Part; the first having had so many Years for Growth, is ready to be felled again, and he may thus go on Year by Year, so long as the Roots will hold out.

The Time for felling a Coppice is during the whole Winter; the Woodman may be set to work in the third Week of September, and the Business may be continued till the first Week in March. After this, the sooner the Produce is got off the Ground, the better: for the Owner is to consider his succeeding Growth. Spring will be now coming on, and the Trees will be very ready, and quick in shooting from the Stumps. These Shoots must not be injur'd, for on their fair Growth depends the Value of the next Fall. For this Reason the sooner all is clear'd off the better; for the Feet of the Cattle, and Wheels of the Carriages, and the Roughness of the Brush Wood will tread down, break and destroy these young Shoots to a great Degree, if this Part of the Work be neglected, until they have made their Appearance, and obtain'd some Length.

Let the Husbandman himself attend the Woodmen in their Work, that he may see the felling perform'd to his Advantage. In the first Place let him leave a Number of regular and well growing Trees at proper Distances for Timber; and let him see these rightly trim'd of their waste Boughs, that their Sap may be so directed as to feed the Trunk, and carry it up even and regular.

Let the others be cut off at five Inches from the Ground, that the Shoots for the next Growth may rise properly; and let them be cut off sloping, and with a sharp Instrument; for all bogging at the Stump does great Mischief. The Success of the succeeding Growths in a Coppice, depends more than can be imagin'd on the employing a good Workman, and seeing that he keeps his Tools in order.

A Readiness and Expedition in the removing the Wood of the last cutting, has been recommended already: when all is clear'd off, the Husbandman is to see the Coppice well fenced as at first, that it may shoot without Interruption or Injury. He cannot be too careful on this Head; for the Mischief he may suffer is very great. The Coppice being well defended, and left to itself, will surprize him by its Shoot of the first Summer, and afterwards it will grow in proportion Year by Year to the next cutting.

After a few Seasons it will be too strong to be hurt by Cattle: but if it happen either through the Owner's Negligence, or in Spite of his Care, that Beasts have got in and crop'd it the first Year, so that it does not thrive, for that is a certain Consequence; the only proper Method is to go over the Shoots at the End of September, and cut them down that there may rise new ones in their Place; and then to see that the Plantation be better defended than before. This is always worth while: for the Difference is great between the Growth of those Shoots in a Coppice which have received no Injury, and those which have been hurt.

CHAP. V.

Of Pollards, or Trees for Shrowding.

FROM the Management of Coppice Wood we are to advance to the Consideration of Timber Trees; but we are naturally stop'd between both, by a particular Kind of Growth, which is properly speaking, neither of the Coppice Wood, nor Timber Tree Kind: this is the Pollard; a Tree of any Sort cut off at ten or twelve Feet Distance from the Ground, and shooting

ſhooting out from that Part a Number of Branches or Poles.

Theſe Poles or Branches are called Shrowds, and the lopping them off is called ſhrowding of the Tree. Theſe are raiſed for the Supply of the Fire, and other ſmall Purpoſes; and are cut at certain Seaſons, not the ſame for all the Kinds, but in general according to their Growth.

Trees intended for ſhrowding, are planted ſometimes in Hedge Rows, and ſometimes in waſte Places: the Kinds that love Water along the Sides of Ditches; and thoſe that bear Dryneſs and Expoſure, on Commons, and in the moſt barren Places. The Water Trees, as they are called by ſome; that is, ſuch as love wet Places, are the quickeſt Growers, the others are according to their Kinds, more and more ſlow.

Pollards are inferior to Coppice Trees in the Quantity of Wood they yield, and in its Value; for the Coppice Wood is fit for many Purpoſes, that the Shrowdings of the Pollards can never anſwer, and therefore brings a better Price; but on the other hand, Pollards are maintain'd, as before obſerv'd, at a ſmaller Expence, indeed it may almoſt be ſaid at none at all; for they require no Fences, they take up no Quantity of Ground; and they are in their Shoots above the Reach of Cattle.

The moſt frequent and moſt profitable Trees for Pollards, according to the three diſtinct Uſes and Situations already named, are the Willow for watery Places; the Aſh for Hedge Rows, and the Oak for Commons. But each of theſe Situations will ſupport ſeveral others to Advantage; and there is ſcarce any Tree that may not be brought to a Pollard at the Owner's Pleaſure.

In general, the Huſbandman ſhould ſhrowd ſuch Trees as are not fit for Timber; or any from which he deſires to have a preſent Advantage, or which he intends ſhall ſupply his Family, or the Market, with Fuel quickly and readily: for there is no Growth ſo ſpeedy as that of the Tree which is ſhrowded.

Trees intended for ſhrowding may be raiſed in many Places, where it would not be worth while to have others, becauſe of the Injury they would do the Ground: for, as to ſhrowded Trees, the Farmer may have the Benefit of grazing under them, while the Tops are growing, ſo that little Produce of the Ground, where that is of any conſiderable Value, is loſt by their Growth: and when their Heads are ſo large that they injure the Growth of the Graſs, they make Amends another Way, for they then afford Shelter for the Cattle, the Neceſſity of which is ſufficiently known to every Grazier.

For the Planting of Trees intended to be Pollards, the Huſbandman ſhould follow theſe Directions.

Firſt, Let him obſerve what Kinds of Trees thrive beſt in the Hedges, or on the Commons about his Neighbourhood; and let this direct him in the Choice of the Kinds for his Pollards.

When he is thus determin'd which of all the Kinds of Trees that are fit for Pollards to raiſe, let him mark out the proper Places whether in Hedges, by Ditches, or on waſte Ground; and let him not ſet them too near one another; for in that Caſe they would defraud one another of Nouriſhment.

For the Generality, the neareſt they ſhould come to one another is forty Foot Diſtance. The Aſh may be planted ſomewhat nearer than other Trees in general, and the Elm nearer than any other Kind: but in this Deſign of Shrowding, between thirty and forty Foot ſhould be the neareſt they are ever allowed to ſtand, let the Soil and Situation be ever ſo good.

Having fix'd upon the Kinds and Places, I would have him raiſe them by planting, not by ſowing; for, in this Caſe, that latter Method would be tedious and unneceſſary. Let him therefore take the young Trees out of his Nurſery at three or four Years Growth, and plant them where he deſigns.

I am particular in adviſing the Huſbandman to take the young Trees out of his own Nurſery, becauſe he will take Care, as before directed, to have that upon a very poor Soil, whence the young Trees being brought to a ſomewhat better, if not entirely good one, will ſhoot vigorouſly.

The Heads of theſe young Trees are not to be cut off at the Time of their Tranſplanting, for two very ſubſtantial Reaſons. Firſt, if they be of the light and pithy Kind, the Wet will be likely to rot the Top where it is cut; and in the next Place, they are not of a due Height, for the Part whence the ſhrowded Tree is cut off, muſt riſe above the Reach of Cattle; elſe they will crop and mangle the young Shoots, and the Shrowding will be worth very little.

At whatever Age Trees are planted, they are not to be cut off for Shrowds till they have ſtood a Year or two to get firm and ſecure Rooting. The beſt Time for doing it is in Spring; and the whole Care reſpecting the Height is, that it be ſuch as to prevent the Miſchief juſt named by Cattle.

In ſome Caſes the Huſbandman may find Trees of a conſiderable Growth, that he ſhall think it worth while to cut off for Pollards; as the Poplar, Willow, and ſome others: but he muſt do this carefully, and the beſt Rule is, that he cut them off at ſome Place, where there is a good Side Shoot to draw the Sap; otherwiſe it is often ſeen that a Tree of this Bigneſs periſhes under the Operation.

The Trees, of whatſoever Kind, being thus cut off, are to be left to Nature, for the ſhooting out of Poles or Branches. Theſe will appear ſoon, and grow very faſt: and when they are of ſuch a Bigneſs as to anſwer the Huſbandman's Purpoſe, he is to lop them. With reſpect to the Time they are to ſtand, no Rule can be given, any more than they could about the Copſe Wood, becauſe ſome Kinds of Trees grow much quicker than others; and the ſame Kind will require a different Time to come to Uſe, according to the Soil and other Circumſtances. The Owner's Eye therefore muſt be his only Rule in this Caſe: he is to conſider the Nature of his Occaſions, and to cut them down when they are fit for thoſe Uſes. Obſerving always that in theſe Shrowds, as in the Growth of Coppice Wood, the Value is always greatly increaſed by allowing a Year or two more in Growth.

The Seaſon for ſhrowding or cutting the Shoots of Pollard Trees, differs in ſome Degree according to their Kinds. As to the Oak and other hard Wood Trees, when they are made Pollards, the Shrowds may be cut at any Time between Autumn and Spring; but it is beſt done in Autumn: but on the other hand, the Willow and other ſoft Wood Trees, including the Aſh, ſhould never be ſhrowded, except in Spring; for if it be done in Autumn, the Winter Rains will be very apt to damage, and will often deſtroy the Tree.

To prevent this Miſchief in any Caſe, Care muſt be taken in cutting off the Shrowds of all theſe Trees, but eſpecially of the ſoft Wood Kinds, that they are cut off carefully in a ſlopeing Direction, and with a ſharp Inſtrument: for in theſe, as in the Coppice Wood Shoots, all haggling of the Stumps does great Miſchief. More depends upon the employing a good and careful Workman on theſe Occaſions, than any one will be aware, who has not minded the ſeveral Conſequences.

Finally, for the laſt Article in the Management of Pollards, I ſhall direct the Huſbandman to fell or ſtub them up at a proper Time; for they do not laſt like other Trees that grow upright and naturally. Pollards uſually, after ſome Loppings, grow hollow and decay. In this Caſe they not only loſe their Value in the Trunk, but the Produce of the Head is leſs, and of ſlower Growth.

For this Reaſon I adviſe the Huſbandman to provide for a Supply in Time, by planting a young Tree of the ſame Kind between every two, and ſhrowding it at a proper Growth. When he is thus prepared let him watch all his old Pollards, and take them before they decay. Cutting them up at this Time they will yield a conſiderable Quantity of good Wood: the beſt of it will be fit for ſome mechanical Uſes according to its Kind, and the worſt for Fuel.

I have ſaid theſe old Pollards are to be fell'd or ſtub'd up; but from Experience I altogether prefer the latter Method. The Price of ſtubing them up will always be return'd in the Quantity of Fire Wood yielded by the Root; and the young Trees will thrive vaſtly the better, for the clearing and ſtirring of the Ground.

In this Manner I would have a Quantity of Pollard Trees always kept up about a Farm, and by the Method here laid down there will be a Supply of them from Generation to Generation.

BOOK IV. PART II.

Of the Management of TIMBER TREES.

CHAP. VI.

Of Timber Trees in general.

THE Plantation of Timber Trees is an Article of vaſt Conſequence to the Publick, as well as of great Advantage to private Perſons: their Uſes in building, and other neceſſary Articles of Life, are ſufficiently known; and our Navy depends upon them. Their Value to the Poſſeſſor is often ſuch as to recover an half-ſunk Eſtate: ſo that, taking in the whole of the Conſideration, it is not eaſy to name any thing a Man can do, that is more for publick and private Advantage together, than planting. It is cheap, and it is eaſy; and it is of all Methods the beſt in which a Man can make Atonement to his Succeſſors for his own Extravagance: and he who ſets about it with Spirit, ſhould conſider he is working for himſelf, his Heirs, and Poſterity.

Theſe are the natural and plain Advantages of planting Timber and Foreſt Trees, and yet the Care of it is, in a Manner, loſt. Neither Laws nor Reaſon ſeem able to affect Men againſt their immediate Intereſt; nor will any thing tempt them to look farther. The Heir cuts down Wood without the leaſt Thought of providing for his Heir, who may probably enough be left in real, in the Place of his imaginary Wants. We ſhall be happy if, by ſetting forth plainly, in the enſuing Sheets, the Eaſe of planting Timber Trees and their Value, we can raiſe again a Spirit for ſetting about that uſeful Work, at the ſame Time that we deliver the neceſſary Directions for the doing it in the moſt ſucceſsful Manner.

Timber, or Foreſt Trees, are planted in Woods, in Parks, in Avenues, and in Hedge Rows, and they ſucceed very well in any of theſe Ways. They may be raiſed from Seed either in the Places where they are to remain, or in Nurſeries, and removed by Tranſplantation; the latter is the more common Way, but the former is the better: this I affirm from what I have ſeen on repeated Trials. The Method by ſowing will ſeldom, however, be prefer'd, becauſe of its Slowneſs; People are eager to ſee the Effects of their Labours, and the other Method ſhews them moſt readily.

When Timber Trees are to be rais'd by tranſplanting, the Sets are to be had from a Nurſery: and the Directions which have been given on that Head, for the raiſing the Supply for Hedges and for Coppice Wood hold good here. The Poorneſs of the Soil of the Nurſery is alſo a particular Article to be regarded in this Caſe.

The Diſadvantage of Trees rais'd by tranſplanted Sets, in Reſpect of thoſe from Seed, is owing principally to ſome Check they receive in the tranſplanting; and this is ſure to be greater when they are removed from a better than from a worſe Soil: the only Thing that could make Amends for the Stop naturally made by this, is the removing them into a Soil ſo much better than their own, that they ſhould feel it inſtantly.

A great deal of Good is to be done alſo, and a great deal of Miſchief to be prevented, by the Method of tranſplanting, of this we ſhall ſpeak at large hereafter: but in this Place there comes a more immediate Conſideration, that of the Soil in which the Plantation ſhall be made.

In this there is a great deal of Difference between the Plantation of the Coppice Wood Shrubs or the Pollard Trees, and that of Foreſt Trees. The former Kinds are intended for immediate Growth and immediate Uſe; but theſe latter are to ſtand a long Time, and on their Strength and Soundneſs, at the End of ſo many Years, depends entirely their Value. This will be more certain in ſome Soils than in others: thoſe Soils, where there is Choice, are therefore to be prefer'd. In general the Trees of theſe Kinds will ſhoot quickeſt in the lighter Soils; but it is in the firmer and ſtronger they grow to the greateſt Value. An Oak in a clayey Ground, makes ſlow Advances, but the Timber is never ſo perfectly firm and ſound as when it grows on this particular Kind.

We are not, however, to infer at once from this, that clayey Soils are the beſt for Trees. A particular Inſtance is not to be advanced into a general Rule: other Soils agree with other Trees; and very well, though not ſo well with the Oak; there is no Need therefore to be particular in the Preference.

The Coppice and Pollard Trees may be planted on any Soil; but 'tis not ſo with the others: as we are to look upon a Plantation of Foreſt Trees as a publick Benefit, we ought to wiſh all poſſible Succeſs to thoſe who undertake it, and to contribute to it by all poſſible Means. In the firſt Place then, the better is the Soil, ſo much the fitter it is for large Trees; and one particular Conſideration comes in here, which is, the Depth. The beſt Soil imaginable, if it lie over a Bed of Rock, though at ſome conſiderable Depth, will ſtarve large Trees: a much poorer with Depth is better.

Without Exception, the richeſt and the deepeſt Soils produce the largeſt and the faireſt Trees. The Quickneſs of their Growth depends, in a great Degree, upon the Goodneſs of the Soil, but their abſolute Growth to their proper Bigneſs and Strength on its Depth. We ſhall find this, on Examination. If we bore into the Earth where Trees grow tall, fine, and regular, we ſhall find it always deep; and on the contrary, wherever the Soil is ſhallow, we ſhall ſee the Trees of the ſame Kinds ſtunted, crooked, and low; with no other Occaſion for that Alteration whatſoever.

Timber Trees would, in general, grow very well in our rich Paſture Grounds: the ſeveral Kinds that love a dry Soil in the higher Paſtures, and thoſe which love wet in the Meadows; but there is no Occaſion to ſacrifice ſuch Land to them: the beſt Method he who is about to plant can take, is to ſearch about his Ground for ſome Place where the Soil is deep, and the Land not turn'd to ſuch Account; and then, in whatſoever Form he chuſes to plant them, he will make it turn, in the End, to a much greater Benefit than any other Part, let what Uſe will be made of it.

There is no Need to be particular as to the Nature of the Soil, provided it have this great Article, already named, of Depth. In general, thoſe which are too dry are the worſt: and to name the beſt of all, it is the loamy Kind. No Matter what be the Colour: but a Soil of this Nature, compos'd, as has been already explained in the fourteenth Chapter of our firſt Book, of Clay, Sand, and a proper Quantity of vegetable Mould, and lying to a proper Depth, with ſome ſoft Bed under it, is the Soil that of all others the moſt univerſally agrees with Trees; and does beſt for all.

There is no Wonder in this Preference, when we examine the Nature of Things; for if we demand what is it that a Tree wants from the Soil in which it grows? the Anſwer is, a Firmneſs that will give hold to the Roots; an Openneſs that will let in the Rains; a Richneſs for Nouriſhment; and a Depth that it can pierce with its Roots In proportion as it advances in Heighth: now all theſe Qualities the loamy Soils have more than any other Kinds.

As to Depth, that is in ſome Degree accidental; but in the general, loamy Soils do not want it, for they are thicker commonly than others, and they uſually lie upon a Bed of Clay which the great Roots are able to pierce, while the others ſpread themſelves in the lighter Soil.

Then the Firmneſs that is in the Loam gives it a Body; and the Sand that is in it breaks it to let in the Rains: while the vegetable Mould, which makes the other Part of the Compoſition, ſupplies its Part of the Nouriſhment. Thus Loam has all the Qualities of theſe ſeveral Soils, and yet has not the Diſadvantages under which they lie ſingly: for though being all thus blended in Loam they make ſo admirable a Soil for Trees, they would neither of them do well alone, excepting for a few particular Kinds.

Clay will give hold to the Roots, but it is cold and has not Nouriſhment: even the Oak that grows ſo ſound in a clayey Soil, expects ſome Moiſture of vegetable Mould, for it does not ſucceed well in Clay alone. Sand that has Warmth enough, wants Body to hold the Roots. And as Clay will not admit the Rains, Sand, though it admits, lets them through, ſo that they do not remain long enough to be of Uſe to the Tree. In the ſame Manner vegetable Mould alone, which receives and keeps the Rains ſufficiently, and affords ſuch abundant Nouriſhment, does not give a ſufficient Hold to the Roots, becauſe it is too looſe and crumbly.

Loam, as we have ſeen, poſſeſſes all the Advantages of theſe ſeveral Soils, without being ſubject to their ſeveral Inconveniences, and therefore Reaſon declares it to be the beſt, as Experience ſhews it is; we ſee all Trees, without Exception, grow well upon loamy Soils; and moſt of them flouriſh: then, as there are certain Plants peculiar to Clay, which will not live in Sand, and ſome that delight in Sand and will not live in Clay, ſo it is with Trees: but in the ſame Manner as all theſe Plants, ſo all thoſe Trees will grow and thrive in Loam.

The loamy Soil then is that which he who is about to plant for Timber is to chuſe; and if he can with Convenience, I would adviſe him to fix upon ſome Spot where Trees have not grown before. For it will be the richer, as its nu-

tritive Parts have not been exhauſted by former Growths.

Some carry this ſo far as to adviſe a Piece of Ground on which no Crop has ever grown; but this is a needleſs Caution, for Timber Trees are to ſeek their Nouriſhment principally at a Depth, to which the Roots of Corn, and other of the common ſuperficial Crops, do not deſcend.

When he has thus fixed upon his Spot, I would adviſe him to uſe the ſame prudent Caution that was recommended on the Subject of Coppice Woods. That is, that if the Soil be not exactly what he could wiſh, he ſuit the Trees to it: and if it differs in ſome Places from what it is in others, he is to uſe the ſame Caution of planting in thoſe particular Places, ſuch Kinds of Trees as that particular Soil agrees withal.

Thus if his Ground be throughout much inclining to the clayey; or what is called a very clayey Loam, let him plant in it the greateſt Quantity Oak: if it be too much tending to Sand, let him plant Aſh in the greateſt Number; and in the ſame Manner let him ſuit the Growth to the Soil, according to thoſe Directions which ſhall be given at large, when we come to treat ſeverally of the Kinds of Foreſt Trees.

At the ſame Time if only ſome one Part of the Ground be very clayey, let him there plant Oak; if ſome Part ſandy, let him here ſet Aſh and Sycamore; and in like Manner if any Spot be particularly wet, let him there plant the black or white Poplar, and ſuch other Trees as love a wet Soil; the ſeveral Kinds of which will be pointed out to him at large hereafter.

CHAP. VII.

Of raiſing Timber Trees from Seed.

WE have obſerv'd in the preceeding Chapter, that ſome raiſe their Plantations of Timber Trees from Seed upon the Spot where they are to remain, others in Nurſeries from whence they remove them by tranſplanting, when they have arrived at a proper Growth. As we have already done in regard to the ſmall Wood for Coppices, we ſhall do in reſpect of theſe: we ſhall deliver the beſt Method of doing each; and the ſeveral Cautions to be obſerv'd in the Practice.

The Seeds of theſe large Trees, are in general large alſo; and they therefore are not to be ſown by ſcattering them at random over the Ground, or ſpreading them in Trenches. They are to be ſet in regular Rows by a Line, putting them carefully into the Earth, and ſeeing them well cover'd. This is the Practice when they are to be rais'd in a Nurſery for tranſplanting: but when they are ſown where the Trees are to ſtand, another Method is to be follow'd, and the Succeſs is more certain.

To this Purpoſe having fix'd upon the proper Places, and Diſtances at which the Trees are to ſtand, a Hole is to be open'd in the Earth for each Tree with a Spade. Let this be dug two Spit deep, and about two Foot ſquare. Let the Earth be well broken, and put in again; and then four or five Acorns, or of whatever Seed is choſen, be carefully ſet in this new ſtir'd Ground.

Let this be done in the Beginning of OCTOBER. When the Ground is laid level over the Seeds, lay a black Thorn Buſh lightly over it, and then raiſe a little dead Hedge, or a ſlight paling round it; and thus leave it till the Seeds ſhoot. This may be called by ſome a troubleſome Method; and indeed it is more troubleſome than the common Way of Planting, which ſpoils half the Trees by Neglect; but all the Expence of digging for a large Plantation will come to but little; and for the reſt, 'tis only doing earlier what in open and expoſed Plantations others do later.

If the Place where the Plantation is made be within a good Incloſure; and no other Uſe be made of the Ground, this Care of fencing round the Seed Spots may be omitted; but there will always be Danger. In the Method here preſcrib'd, the Ground may be uſed for the common Purpoſes of Huſbandry, all the Time the Trees are growing up to a Heighth; and they will be defended by the firſt Work, till they are out of the Reach of Danger.

No Method ſo well gives Trees the Advantage of growing up for the firſt Years in perfect Security and Quiet; and few conceive how much the future Beauty and Value of the Tree depend on that Article. The leaſt Hurt from Man or Beaſt, while young, may blemiſh a Tree for ever: nay, the very blowing of the Wind will ſometimes do it an irreparable Miſchief. It is at this Seaſon only they require Care, but here they really require the greateſt.

According to this Plan, the Owner will be ſure of every Step he takes: he will have a Plantation, every Shoot of which ſhall certainly thrive; and every Tree be regular and beautiful: and this is the Method we prefer for raiſing Plantations, though we ſhall do Juſtice alſo to the other.

When the Seeds in theſe ſeveral Spots have ſhot above the Ground, let the Place be kept clear of Weeds, and their Growth for a little Time carefully watch'd. As ſoon as they are ſo far advanced that the Eye can judge of them, let one be marked for the reſerved Plant that is to ſtand, and be the future Tree; and let the others be drawn up and ſet in Hedge Rows, Coppices, or where the Owner pleaſes; leaving the favourite Shoot alone to have the Benefit of the Ground. This will ſhoot up at a ſurprizing Rate, and almoſt always with perfect Regularity. If from any Accident it prove faulty, let it be taken up, and one of the beſt of thoſe that had been tranſplanted, again removed and ſet in its Place, watering, and ſhading it, which may eaſily be done by means of the Hedge or Paling; and uſing every Method to forward its Growth, that it may not be too far behind the others.

Thus is a Plantation of Timber Trees rais'd by ſowing; and no farther Trouble is requir'd about them.

CHAP.

CHAP. VIII.

Of propagating Timber Trees by Tranſplantation.

IF the other Method by tranſplanting be prefer'd from the particular Fancy of the Owner; or from the particular Circumſtances of his Situation, which may ſometimes reaſonably influence him to make that Choice, though naturally and generally the other is beſt, the following is the Method to be obſerv'd.

Firſt then, let a Spot be choſen for a Nurſery on a poor Soil; and let the Seeds of the ſeveral Timber Trees intended to be raiſed, be ſet according to the Directions before given by a Line. When they are come up, let them be thinned where they have riſen too thick, pulling up the weakeſt Plants.

When the others are of a proper Growth, let them be tranſplanted into the Places where they are to ſtand, obſerving the following Directions; on the punctual regarding of which, a great deal of the Succeſs of this Undertaking will depend. All Trees are injur'd by removeing, but that Hurt is uſually much greater than it need be from the improper or careleſs Manner of removing them.

In the firſt Place, as to the Time of tranſplanting them, the beſt is when they are of two Years Growth. Moſt People do it later, but I have found fewer Accidents when they were thus young, than at any other Time.

Let them be taken up out of the Nurſery with more Care than is uſually allowed. Let the Place be open'd to receive them; and let them be brought to it with as much of the Earth of the Nurſery about the Root as poſſible.

Let the large ſtrait downright Root, in ſuch Trees as have one, be cut off at the End; and the Hole be deep enough to receive it without bending. This is what is called the Tap Root; and the preſerving it in its proper Direction, is of great Conſequence to the regular Growth of the Tree. Let the other Roots be as evenly laid in, and as little cruſh'd and injur'd as poſſible: and when the Earth is put over it, let it have a careful watering to ſettle and fix it about them.

Let Care be taken that the Hole into which the young Tree is ſet, though deep enough to receive the tap Root, be not ſo deep as to bury the others below the beſt Part of the Soil. This is a common Fault of thoſe who in ſmall Plantations will be over careful. By this Miſtake they ſet all the young Roots in a Clay or a Gravel, whereas they might have diſpoſed them in a good vegetable Mould. The lodging theſe Roots carefully in the beſt Part of the Soil, and keeping them evenly diſpos'd, and well ſpread out, with Earth between them, is a very great Article: and to this Purpoſe when the Soil is very thin or ſhallow, it is beſt to keep them in it, and if need be, to raiſe the Earth about the Bottom of the Tree, rather than ſink that too low.

The Diſtances at which they ſhould be planted, we have already ſaid depend upon the Nature of the Tree. The Oaks ſhould ſtand at forty Foot Diſtance every Way: the Elms at thirty; and all other Trees at ſome middle Diſtance between theſe. This, and the other particular Directions, will be given in treating ſeverally of the diſtinct Kinds; we are here ſpeaking of Planting in general.

In the ſame Manner is to be underſtood the Preference given to ſowing above tranſplanting: it is deliver'd of Trees in general. We ſhall ſhew hereafter how either Method ſuits beſt with each particular kind of Tree.

The Directions here laid down will enſure a general Succeſs, when they are practiſed with due Care in the Tranſplantation of Trees of two or three Years Growth. But as it is a common, and, in many Caſes, a very right Practice, to remove ſuch as are of a larger Size, it will be uſeful to ſet down here the Cautions and Expedients which are to be uſed in removing them, and to aſſiſt the Succeſs.

When a Tree of ſome conſiderable Growth is to be removed, let the Hole in which it is to be ſet be thoroughly prepared before it is brought; and in the taking it up out of the Nurſery, let there be as large a Quantity of its own Earth as well may be, removed with it, and kept cloſe to the Roots.

Before it is taken up, let there be a Mark made upon its Bark with Chalk, facing the South; and let Care be taken in the ſetting it in its new Place, that this Mark faces due South again.

There is more Reaſon for this than is generally imagin'd, for the Sap naturally riſes moſt in all Trees on that Side which is next the Sun; and if the ſame Side be not kept next in the Removal, this alone will make a Confuſion, and be a Check upon the Growth; which is the great Thing to be avoided in Tranſplantation.

The beſt Seaſon for tranſplanting Trees which are ſomewhat grown, is in the latter End of OCTOBER: for the young ones 'tis as well to do it ſomewhat earlier. The watering of new planted Trees, which is ſo neceſſary to all, is the more needful as they are the larger; and they will then bear it alſo in greater Quantity; for too much Water in a cold Seaſon to a very young Tree ſometimes chills it.

Particular Care muſt alſo be taken in theſe Caſes, to ſpread thoſe Roots evenly which ſtand out beyond the Clump of Mould taken up with the Tree; and to cloſe the Earth well about them.

When the Tree is thus planted upright and ſteady, it muſt be ſtaked up to keep it ſo. One or more Stakes are to be thruſt firmly into the Ground for this Purpoſe, and the Tree is to be faſten'd to them with a Hay-band; and it is always good to put a Handful of Moſs between the Stakes and the Tree, that they may not rub and injure the Bark.

If it be planted where Cattle may damage it, it muſt be ſecur'd by Buſhes of black Thorn, or by a Hedge, or paling round it: for they will prevent many a Tree from growing, by rubbing themſelves frequently againſt it; beſide their injuring it by cropping it if in their Reach.

Farther, to ſecure the Succeſs of the Plantation, it will be proper to lay a Quantity of freſh cut Fern, or Pea or Bean Stalks, or any Thing of that Kind, all about the Roots. This ſerves to keep the Earth moiſt about them; and by Degrees theſe Plants rot and decay, and the Earth receives their Subſtance, which is waſh'd in by Rains as a Manure, greatly improving the Soil, juſt when it is moſt wanted; and promoting the Growth of the Tree when there is the Fear of its being check'd by the Removal.

If the Place or Seaſon make it inconvenient, to get any of theſe Things to lay about the Root of the Tree, it is adviſeable to lay a good Quantity of large Stones there. Theſe anſwer the ſame Purpoſe in keeping the Ground moiſt; and they alſo preſs it down ſteady and firm to the Roots.

CHAP. IX.

Of tranſplanting Trees at a large Growth, or at improper Seaſons.

AS there may ſometimes be Occaſion to remove Trees of a very large Growth, or at an improper Seaſon of the Year, we ſhall add here the beſt Methods for doing either; and the Cautions that are neceſſary to be uſed to prevent the Loſs of the Tree, which naturally would happen, if ſuch Tranſplantations were ſet about raſhly, and without the neceſſary Care.

When there is Occaſion to remove a very large Tree, the Method to be taken is this. A Year before the Time let the Earth be open'd at ſome moderate Diſtance in Form of a Trench; ſo as to leave a Ball of Earth about the Stump, of five, ſix, or more Feet in Diameter, according to the Bigneſs of the Tree. When this Trench is dug to the needful Depth all round, and the Side Roots at that Depth are all cut through, let a Rope be applied to the upper Part of the Tree, and by the Strength of three or four Men, let the Tree be pulled on one Side till the Workman can get at the ſtrait downright Root or tap Root. Then let him cut through that Root with his Axe, and when this is done, let the Tree be ſet up ſtrait again. When it is up, let the Earth that was dug out of the Trench be thrown in again, and then tying two more Ropes round the upper Part of it, drive three Stakes at ſome Diſtance in the Ground, and faſtening the other Ends of theſe Ropes to the Stakes, the Tree will be able to ſtand againſt the Wind, which otherwiſe would blow it down; as which ever Way it is bent by the Blaſt, there will be a Rope to pull againſt it. In this Manner let the Tree ſtand till that Time next Year; or if this have been done in Time, and it be allowed to ſtand two Years, it is the better.

The beſt Seaſon for removing it, is juſt after a good Froſt. Let the Hole in which it is to be ſet be made ready; and the Earth about the Root well wetted before the Froſt, that it may bind together in a firm Lump about the Root; and in this Condition let it be removed and ſet in the Hole where it muſt be ſecured by Ropes and Stakes as before directed.

If Trees are to be tranſplanted in Summer, the great Art is in preparing the Earth for their Reception. They muſt be taken up with all the Cautions already given, and the Earth ſhould be wetted to make it hold together about them. Then in the Hole where they are to be planted, there muſt be a large Quantity of fine Mould mix'd with Cow Dung, and beaten up with a ſufficient Quantity of Water to reduce it to a Paſte.

When the Hole is thus prepared, the principal Branches of the Tree muſt be ſhorten'd; and it muſt be removed with a good deal of Earth about the Root; it muſt be ſet upright in this Paſte, and fine Mould thrown in and preſſed down upon it: then the Hole being filled up, is to be cover'd with Turf; and a Quantity of Stones laid all about the Bottom of the Trunk to keep the Ground moiſt, and to preſerve the Tree ſteady.

In this Manner; and by theſe Methods carefully follow'd, Trees may be tranſplanted when of ever ſo large a Size; and at ever ſo improper a Seaſon. But theſe are Occaſions which ſeldom offer in the Huſbandman's Way, Pleaſure demanding them much oftener than Advantage. We have, however, given the Rules for doing it, that nothing might be omitted; and having thus treated at large of raiſing and tranſplanting Trees in general, we ſhall advance to a full Conſideration of each Kind in particular; and of the peculiar Management each requires.

BOOK II. PART III.

Of the ſeveral Kinds of TIMBER TREES.

CHAP. X.

Of the Oak.

WE have already ſpoken of the Oak at large among other Timber Trees, in delivering what in general concerns their raiſing; but we are here to conſider that of this Tree in particular. We ſhall in this, and the ſucceeding Chapters, as much as poſſible avoid Repetitions of what has been ſaid already in that general Diſcourſe; reſerving to each Head what is, in ſome Degree, peculiar to each Tree.

The Oak is a large Tree with a rough Bark, ſpreading Branches, and large Leaves, deeply

wav'd at the Edges: the Flowers are inconſiderable, they are a Kind of brown Threads: the Fruit is the Acorn, ſtanding in a Cup, and growing in ſome Trees on a longer, and in others on a ſhorter Foot Stalk; from which Difference ſome have diſtinguiſhed two Kinds of Oak. Others have, in the ſame Manner, divided the Oak into two Kinds, one of which riſes more in Height, and the other, which they call the wild Oak, ſpreads more into Branches. But theſe are accidental Varieties, not diſtinct Kinds.

The Oak will grow in almoſt any Soil: this we ſee in Fact, becauſe we find Oaks on all Kinds of Land. We ſee it on clayey, ſandy, and ſtony Ground: but thoſe who have made ſtrict Obſervations declare, that in the clayey Soils it obtains moſt Firmneſs, but in theſe the Growth is ſlow. The beſt Earth for Oak, where there is Choice, is a rich Loam. This is a ſound and commonly a deep Soil. Too much Wet is an Enemy to the Oak, ſo that it ſhould be guarded againſt; and 'tis principally for this Reaſon that it grows beſt on ſomewhat riſing Grounds, for they are naturally more dry than the abſolute Flats on which the Wet lodges and remains.

When the Ground is too moiſt the Oak puts out moſt Branches, and the Trunk is defrauded of its due Nouriſhment; in very dry and expoſed Places it grows low and ſtubbed.

The Timber in too moiſt Ground is ſofter, and in theſe hilly and barren Places it is harder than its uſual Quality, but 'tis there of an uneven Grain, and leſs uſeful.

The fineſt Oak Timber is that which has grown on a firm good Soil, rather enclining to Clay than any other particular Quality, and where there is not too much Moiſture.

The Oak is propagated three Ways; firſt, from Seed, or the Acorn; ſecond, by raiſing in a Nurſery, and then tranſplanting; and, thirdly, by taking up young Sets out of the Woods, where they have riſen from the fallen Acorns, and are uſually plentiful enough.

Of theſe Methods I altogether prefer that of raiſing the Oak from the Acorn, in the Place where it is to grow. The Oaks from the Nurſery are commonly twice tranſplanted to come to their ſtanding Place, and this gives them two Checks greater or leſs; and diſpoſes them twice to an Unevenneſs in the Growth: as to the Sets taken out of Woods, they are the worſt Way of all. Idleneſs or Frugality may tempt thoſe who will not raiſe, or purchaſe the young Sets out of a Nurſery to do this, but theſe wild ones having been rais'd under too much Shade, are uſually very ill ſhaped; and as they are planted out into more expoſed Places, they commonly get an ill Growth.

CHAP. XI.

Of raiſing Oaks by Tranſplantation.

IF any one in ſpite of theſe Diſadvantages will plant the wild Sets, the Method he is to take is to cut them off cloſe to the Ground, with a ſharp Knife, and by a ſlanting Stroke, as ſoon as they are planted. This gives the Root Time to recover ſome Strength, and as it affords a new Shoot, that is often better than the original Plant. But in this Caſe the Diſadvantage is plain, for it is evident that it would be better this Shoot roſe from the Root than from a Stump.

Thoſe who raiſe Oaks in a Nurſery for Tranſplantation, muſt obſerve a different Method from what is to be followed by ſuch as ſow them where they are to ſtand. They are to proceed thus. Let the Acorns be ſhook, as ſoon as fully ripe, from a ſtout Branch of a well growing Oak; and immediately ſown in the Nurſery, for the Air withers them.

They are to be ſet in Lines, at two Inches aſunder, and about two Inches and an half deep in the Ground. They will ſhoot the ſucceeding Spring, and they ſhould be ſuffer'd to ſtand till that Time Twelvemonth: then they are to be tranſplanted into another Part of the Nurſery, and ſet at eighteen Inches Diſtance, in Rows three Foot aſunder. They are to be watered a little when firſt tranſplanted, but this muſt be carefully done, for too much Water is apt to hurt the Oak, eſpecially when young.

The Oak is a particular Tree, and requires, as well as deſerves, a particular Care in its Management. In many little Reſpects the Conduct is to be different from that obſerved in the raiſing the Generality of Trees; and it is to a Want of Regard to theſe, that ſo many young Oaks are loſt more than of other Trees.

The young Trees thus tranſplanted are to be watered ſometimes in dry Seaſons, and kept clear from Weeds. It is alſo good to dig between the Rows: for this, by breaking the Soil, affords them a greater Supply of Nouriſhment, and at the ſame Time it cuts off the ſtragling or far-ſpreading Roots, which will make the young Trees bear their next Tranſplantation the better.

During the Time they ſtand in theſe Beds they are to be regulated in their Growth, but in this only a little is to be done. They who cut off the Head deſtroy the Tree, for if there be not a leading Shoot to conduct the Top, the whole will periſh. Neither are many of the ſide Branches to be taken off, but only ſuch as tend to too much ſpreading. The Planter is to remember that the Trunk of the Oak is to be his beſt Benefit; he muſt therefore cut off ſuch very ſpreading Branches, as would draw the Sap away from it and ſtarve it: but it is prudent to leave a competent Number of the others, to draw up the Sap. When an Oak in this young State is too cloſe prun'd, the Head is always ſeen to grow over proportioned, and weighs down the Tree and ſpoils its future Progreſs.

When the Trees have thus ſtood about four Years; that is, when they are between five and ſix Years old from the ſowing, they may be conveniently tranſplanted. They are at this Time of a pretty Size, and having been thus prun'd ſhew well. It is dangerous to move them in the common Way, when they are older, for the Oak bears removing, when grown to a Size, worſe than any other Tree.

The Time for tranſplanting them is juſt before they begin to ſhoot; and it is prudent to chuſe a ſhowery Seaſon: if no Rain fall they

muſt be gently watered, as before directed, and ſtaked up to keep them ſtrait.

This is the Method for raiſing Oaks by Tranſplantion; and when they are wanted for Beauty and Ornament, as for Chumps in Parks; and for Wilderneſſes in large Gardens, this is a very good Way, becauſe they may be had of a proper Growth from the common Nurſeries: or from the Owner's own Stock, rais'd there for other Purpoſes. But when Oaks are intended for Timber; and Uſe and Value are more ſtudied than Ornament; 'tis by much the beſt Method to raiſe them from the Acorn, in the Places where they are always to continue.

CHAP. XII.

Of raiſing Oaks from the Acorn.

THE Directions which have been given for raiſing Trees in general from the Seeds, in the laſt Chapter, might ſeem here, and on the like Occaſions hereafter, the Repetition of a great many needleſs Words; but in each we ſhall deliver whatſoever there is required particular for the raiſing of each Kind.

When the Oak is to be rais'd immediately from the Acorn, a different Method, and different Seaſon are to be obſerved for ſowing.

Let the Acorns be gathered when full ripe, from a thriving Tree, and immediately ſpread upon the Floor of a dry ſhady Room: when they have lain a Week, frequently turning them, let them be put up in large Garden Pots, with a Quantity of dry Sand, and laid by for the Winter.

Early in Spring let the Ground be marked out where the Plantation is to be made, and at the Diſtance of forty Foot every Way, let the Holes be open'd for receiving the Seed. Theſe are to be dug two Spit deep, and the Earth well broken, four or five Acorns are to be put into each, and cover'd two Inches deep, and when they have ſhot, and acquir'd a little Growth, all the Plants, except the one beſt in each Hole, are to be taken up as directed at large in the laſt Chapter. And that ſingle Plant in each Hole is to be nurſed up for ſome Years with due Care.

The Head of theſe young Trees is to be ſuffered to grow, and none of the Branches are to be cut away, except ſuch as ſpread out too wide, as in the Nurſery; and if it happen that in ſpite of the Care in the Choice of thoſe Shoots which have been ſuffer'd to ſtand, any one be uneven; the beſt Method is to cut it off at the Ground, and wait for a new and better Shoot.

A Plantation of Oak thus made, if the Soil be tolerable, is a Fortune for the Succeſſor in the Eſtate; but it is not limited to that; Men enter too late upon theſe Studies, otherwiſe they might reap the Benefit of their Plantations themſelves. If a Man would begin to plant at eight and twenty, and ſhould live to ſee ſixty-three, there is a Space of five and thirty Years, which is a Time for raiſing even an oak Plantation, ſlow as that is in Growth, to very conſiderable Value, though not to its full Price, or nearly to that.

It is not eaſy to give what can be call'd a middle Calculation for the Growth of the Oak, it differs ſo prodigiouſly in Reſpect of the Soil, Situation, and other Circumſtances. But this I can ſay from my own Knowledge, that Oaks are now to be ſeen in this Neighbourhood, which were planted thirty-four Years ago in the Acorn: And the laſt Tree among them is fourteen Inches diameter in the Trunk.

An Oak of this Bigneſs is but advancing toward the proper Time of felling, and towards its Value, but if the Neceſſities of the Owner induced him to fell theſe at this Time, the Price of the worſt Tree among them would pay for the Labour and Charge of the Plantation.

If the young Plants, when they riſe in theſe Spots, appear almoſt above the Ground, or ſtand too high with their Roots, the beſt Method is to lay up a Parcel of fine Earth againſt the Bottom of that which is the moſt thriving Shoot. This happens ſometimes from the Acorns being not ſet deep enough; and ſometimes from the Weather: for after a Froſt the Mould will riſe, and bear up the young Shoot with it.

Acorns are not to be buried too deep, eſpecially in a moiſt Soil, for they often rot: and, on the other hand, they muſt not be ſet too ſhallow; for it not only makes the Shoot ſtand too high; but frequently the Field Mice find them out, and devour the Hopes of the Plantation.

The Quantity of Ground taken up by this Plantation, at forty Foot diſtance, is not to be ſuppoſed waſted: for though the Oaks will, in their larger Growth, require that Diſtance, they do not at firſt. For many Years Aſhes may be rais'd upon the Ground between the Oaks, for Poles, and cut to a great Advantage. Underwood of all the ſhrubby or Coppice Wood Kinds, may alſo be planted for a Time, if the Ground be fit for it: or it may be graz'd, and will loſe little of its Value for many Years. Nay the planting the Trees at this Diſtance is the only Way to preſerve a Value in the Ground for theſe Purpoſes; and when the Soil is good, it will continue to yield fine Paſture.

For an Inſtance of this I need not ſend the Reader farther than to that elegant and noble Plantation BUSHY-PARK: where, all about the Caſcade, he will ſee Oaks of a very noble Growth, at about forty Foot diſtance, more or leſs, and the whole Surface of the Ground under them as green as the fineſt Meadow.

CHAP. XIII.

Of the Uſes of the Oak.

NO Plantation whatſoever exceeds that of Oak, when made in this Manner: and to thoſe who will ſuffer it to ſtand a proper Time, none equals it in Value. By this Management the Trees will all riſe with a ſingle ſtrait and upright Stem, and their Branches ſpreading every Way with a beautiful Regularity, make, when cloathed with their large and fair Leaves, a beautiful Appearance. Their Shade is preferable to that of any Tree whatſoever: their very Imperfections and Excreſcencies, the Oak Apples, Oak Cones, and Oak Grapes are beautiful; and the Air is perfumed and rendered healthy by blowing over them.

Among

Among the Excreſcences of the Oak I have not followed the common Cuſtom of ranking the Herb, call'd Miſletoe; becauſe it is not an Excreſcence, but a regular Plant, riſing from its own Seeds, but whoſe Place of Growth is not the Ground, but the Bark of ſome Tree; and no Trees afford it ſo ſeldom as the Oak.

Its Fruit, which a good and well-grown Oak bears annually in vaſt Abundance, is an excellent Food for Hogs. No Fruit feeds them ſo well, it gives their Fleſh alſo an excellent Taſte. The Flavour of the Westphalia Hams is owing to this Food. They are made from wild Swine that live in the Foreſts; and it would, doubtleſs, be an Improvement of our Hogs Fleſh intended for that Service, if the Creature were fed with Acorns.

That they give a Flavour to the Fleſh of ſuch Hogs as eat them in Abundance, is not to be queſtioned; for our Country People, who are not accuſtomed to that Taſte in Bacon, always feed their Hogs ſome Time with Peaſe after the Acorns, to take off the Flavour.

The Effect of Food on Creatures in giving a Taſte to their Fleſh, is not to be doubted. The Heath-Cock of Germany is not eatable in Autumn, except by the Peaſants, becauſe its Fleſh taſtes ſo ſtrongly of the Juniper Berries he eats at that Seaſon; and as to the Effect of particular Food on Hogs, an Inſtance is given in the Philoſophical Tranſactions, of the very Bones of a Pig being ting'd red, by its eating Madder Root at a Dyer's.

The Hog is the Creature that eats Acorns moſt freely and naturally, and is beſt fed with them; but what Nature has meant as Food to one Animal, may, by proper Management, or in Neceſſity, be made Food to others; all Poultry will eat Acorns if broke ſmall, and given them among other Food, and nothing fattens them more. They have alſo been given to Oxen, and other Cattle, among their dry Food; and we read that before the Cultivation of Land was ſo well known, they were, in Part, the Food of Mankind.

Their Effect in fattening the Hog is ſupported by ſufficient Experience. A Peck of Acorns a Day, with a little Bran, will, it is affirmed, upon good Authority, make an healthy Hog encreaſe a Pound each Day in his Weight, for fifty or ſixty Days together.

The Bark of the Oak ſerves the Tanner, and fetches a large Price; the Dyers alſo uſe it: and it has been diſcovered ſome Years ſince, that the young Branches of the Oak cut and ground to Pieces in a Mill, anſwer all the Purpoſes of the Bark, and that in as great Perfection on theſe Occaſions.

We have mentioned Saw Duſt among the Articles uſeful as Manures; and Experience ſhews that none is ſo excellent for that Purpoſe as the Duſt of the Oak: this is natural enough, becauſe the Oak is the moſt firm and ſolid of all our Timber. Thoſe who have try'd the Experiment ſay alſo, that of the Kinds of Wood Aſhes uſed in dreſſing of Land, the Oak claims greatly the Preference.

All theſe however are but, as it were, accidental Articles of Value in the Oak, its great Worth is in the Timber, which in Solidity, Strength, and Soundneſs, exceeds all our other Kinds, and is therefore of all the moſt fit for great and laſting Uſes. Of all Kinds of Wood yet known in this Part of the Globe, the Oak is in its Service the moſt univerſal.

Beſide its prodigious Uſe in our Shipping, it is called for, on a thouſand Occaſions, in Buildings, and for Inſtruments. It reſiſts the Injuries of Weather more than any other Wood, which is not a Wonder, for even the Fire takes Effect upon it much ſlower than on any other Timber whatſoever: and ſome of it is ſo hard that the beſt Tools will ſcarce work upon it.

In Water-works, where the Timber is expoſed both to the Air and the Water, no Wood ſtands like the Oak: and no Wood is equal to it in the Support of Burthens. The Ebony and ſome other foreign Woods, when they are very hard and firm, cut as difficultly as Oak, but if they are try'd in the ſupporting of Burthens, they ſtart and fly under half the Weight that a Piece of Oak of the ſame Size will ſupport with perfect Safety.

Even the Defects, as they naturally appear of Oak, ſerve to give it Strength for certain particular Purpoſes. Thus it is not unuſual for an Oak Trunk to grow a little twiſted: this may be diſcovered through the Bark as it is ſtanding, but is very viſible when the Tree is fell'd and ſtrip'd: the Trunk of ſuch an Oak is uſeful beyond any other, for the ſupporting vaſt Weights. Where Poſts and Columns are required for ſuch a Purpoſe, nothing equals it.

In Buildings the ſtraiteſt, fineſt, and eveneſt growing Pieces of Oak are uſually wanted, and they bring their Price accordingly; but for Engines where a vaſt Strength is required, the Body of one of thoſe ſtubbed, and rough grain'd Oaks, which are not fit for other Purpoſes, and which are ſo hard that a Tool will ſcarce pierce them, is ſuperior to any thing.

There is no Oak, while ſound, that is not fitted for ſome Purpoſe. Thoſe Parts which will not do for greater Uſes makes Pales, Poſts, Coopers Ware, and Laths; all which bring their Price to the Owner: even the leaſt Pieces are worked into the Pins and Pegs us'd in tyling, and that Way are of Value.

Oaks that grow crooked, and are firm withal, make what they call Knee Timber for Shipping. The knottieſt and rougheſt Pieces are fit for Piles in Water-works; and Mill Wheels, and Spokes for other Wheels are made from the proper Pieces.

Beſide all the Uſes of the Oak in its various Conditions, conſider'd as a Timber Tree; we are yet to conſider it as a Part of the Coppice Wood Plantation; and no Kind is there more valuable. The Oak maintains its Character in every Condition, and is every where of Value.

When the Oak is ſown among the Coppice Wood, to be fell'd with it at twelve or fourteen Years Growth, it yields excellent Poles for Hoops. 'Tis uſual to make theſe of Aſh, and ſome take Hazel; but the Preference is due to the Oak Hoop beyond all Degree of Compariſon: the Aſh does not exceed the Hazel for Hoops half ſo much as the Oak exceeds the Aſh. An

Oak Hoop will laſt out ſeven of any other Timber.

The ſmaller Kinds of Poles ſerve as Staves, and the leaſt make our walking Sticks. The Root of the Oak where it is knotty and firm, has alſo great Beauty when uſed by the Turner or Inlayer.

Thus we ſee that this ſerviceable and univerſally uſeful Tree ſupplies us with Materials of all Kinds, as Timber, from the Ribs of a Man of War to a walking Staff, and from the main Beam of a Houſe to the Pegs in the Tiling: not the leaſt Particle of it but is uſeful. Even ſuch as is fit for nothing elſe in the Coppice Oak is good for firing, whether ſplit into Billets from the larger Pieces, or cut into Faggots it excels other Wood. The Charcoal that is made of the Oak is better alſo than any other.

CHAP. XIV.

Of the Growth of Oak Trees.

THE Growth of the Oak is not only very different on various Soils; but it has been found by nice Obſervation, to vary exceedingly at different Periods on the ſame Place. For Inſtance, an Oak has been obſerv'd to grow very freely and very well for twenty ſucceſſive Years: at the End of this Time it has come to a ſtop, and has for ten or a dozen Years made little Progreſs. From this Time it has begun to grow again, and has continued in its uſual Way increaſing viſibly in Height and Thickneſs.

This, though ſeeming to ariſe from ſome hidden Cauſe in the Tree itſelf, is really owing to the Soil. The Tree being planted in a good Earth, ſpreads out its Roots, and flouriſhes extreamly well, ſo long as they remain within the Compaſs of that Coat or Layer of the Ground; but when they have pierced through that, and got into ſome other ſtarving and poor Earth, they receive little Nouriſhment, and the Tree comes to a ſtand. It would continue ſo all along, were it not that the ſame Roots puſhing deeper and farther, find good Soil again. Thus in the preſent Inſtance, the good Soil holds the Roots twenty Years, and affording ſufficient Nouriſhment, the Tree all that while grows freely. At the End of that Time they penetrate into ſome unfavourable Layer; there they are kept twelve Years, all which Time the Tree barely lives, and hardly grows at all: till at the End of this Period the Roots piercing into another Bed of good Matter, ſupply the Tree as at firſt, and it then grows and increaſes again as it did from the Beginning.

It has been obſerv'd already, that the Oak will grow in any Soil, though it thrive differently according to the Nature of that Earth: but the Difference that is made by Soils in the Speedyneſs or Slowneſs of the Oak is not all: for the very Grain of the Wood is affected by it.

On barren Heaths, where the Bottom is ſtony, the Oak is ill-grain'd and coarſe: the Grain of that Oak which has been rais'd in ſandy Soils, is ſmoother and evener than any: but that which has been fed by a good firm Loam, inclining to clayey, is the right ſubſtantial and true grain'd Timber.

In the Foreſt of DEAN in GLOUCESTERSHIRE, there have been long ſince Iron Works, and a great deal of the Ground is cover'd with Slags of the Remains of thoſe old meltings. Theſe are taken up and wrought at preſent by the People who work the freſh Ore alſo, and that to a great Advantage. From thence has riſen an Opinion, that theſe Slags were filled with a freſh Quantity of Iron from the Air. But this is an Error. The Truth is, that the old Workmen did not ſo well know how to get all the Metal out of the Ore, as our People do at preſent; or that having great Choice and Plenty, they did not trouble themſelves to work near: however that be, 'tis certain that all the Iron now found in theſe Slags was left in them at that Time: the Occaſion of naming them here is, that from theſe Maſſes of Slags, Oaks grow in Abundance in that Foreſt, and to a great Value. A great Part of their Roots are ſpread among thoſe Slags, ſome piercing down below them, and others running through them to a better Ground that lies at a Diſtance: for the Roots of Trees ſpread farther than is imagin'd. In HAMPSHIRE, and other Places, Oaks are ſeen growing out of Stone Walls, and riſing to a great Height, and to the containing very conſiderable Quantities of Timber.

Though the Oak will grow any where, we ſee how it will be ſtop'd in its Growth by the Interpoſition of a Bed of unfavourable Matter in its Way. Theſe Things are not ſet down here for Curioſity, or to raiſe Mens Wonder, but for Uſe. As the Planter ſees an Oak may be thus ſtop'd for a Courſe of Time, ſo that it ſhall be as good at twenty as at two and thirty Years Growth, it will be worth his while to take all Precautions to prevent ſuch an Accident. We have directed the Uſe of an Auger for boring the Ground in Search of Marle, it will be adviſeable that the ſame Inſtrument be uſed in examining the Earth, where an Oak Plantation is deſign'd to be rais'd: and that the Planter may know to what a vaſt Size and Value Oaks will grow when the Soil favours them, not only in Condition, but Depth, we ſhall give him an Account of what Bigneſs ſome have ariſen to in ENGLAND, as ſupported by unqueſtionable Authority.

In WORKSOP Park the Duke of NORFOLK had an Oak which ſpread almoſt three Thouſand ſquare Yards. Near a Thouſand Horſe might ſtand under the Shade of it: this is affirm'd upon very good Authority, and will appear the more credible from other Inſtances of the vaſt Size of ſome of thoſe Trees. PLOT in his OXFORDSHIRE, tells us of an Oak at CLIFTON, that ſpread eighty one Foot from Bough End to Bough End, and ſhaded five hundred and ſixty ſquare Yards of Ground. 'Twas computed five and twenty hundred Men might ſtand ſheltered under it. The famous Robur Britanicum in Lord NORREY's Park at RICOT, was computed to be able to ſhelter between four and five Thouſand Men.

The Mainmaſt of the old Royal Sovereign was ninety nine Foot long, and near a Yard thick,

thick, all of one Piece of Oak; and ſome of the Beams of that Ship were made from another Oak near five Foot thick, and were forty Foot in Length.

What muſt be the Value of theſe Trees is very evident; and there is no Reaſon why any Man who will take the Pains in raiſing his Oaks from the Acorn upon the Spot with due Care, and ſee that the Soil be perfectly fit for the Growth, may not leave an Inheritance of ſuch to his Poſterity.

The Oak requires leſs lopping than any other Tree, whether it be intended for Beauty, or for Uſe. Nature rarely over-proportions the Branches to the Trunk; and they ſpread with great Beauty, and grow in Value with it. If there be any Danger of a Branch growing to an immoderate Extent, ſo as to rob the Trunk of its Nouriſhment, that is ſeen in the firſt Years; and Directions have been given already for the retrenching ſuch: for the reſt, the Oak does beſt when left to Nature; and, according to the beſt Accounts that can be had, the common Opinion of the Time of its Growth, Duration and Decay, ſpeaking in round Numbers, is not far from Truth. Oaks have been known to continue in a State of Growth and Increaſe ninety or a hundred Years; and we have Records of the planting of Oaks in ſome old Parks, that are of near three Hundred Years ſtanding, and now are in a miſerable State of Decay.

'Tis idle to ſuppoſe the exact Period is determin'd by theſe exact Numbers, but probably a Tree that attains its full Maturity ſo ſlowly, remains a long Time ſound, and is long in decaying; and this the Firmneſs of the Oak Wood makes it the more natural to imagine.

CHAP. XV.

Of the Felling of the Oak.

IF it be true that an Oak continues growing a Hundred Years, certainly 'tis beſt not to fell that Tree till after the full Period of the Growth, when it can conveniently be ſuffer'd to ſtand ſo long; but with a View of Advantage, it is idle to think of its ſtanding any longer: for certainly it can never be better than when at a full Maturity.

This then is, in general, the beſt Time of felling, but no particular Period can be limited for each Tree; for of thoſe raiſed from Acorns of the ſame Bough, and ſown in the ſame Soil, ſome will thrive better than others.

When a Quantity of Timber is to be felled, let it be firſt well examin'd, and let the Workmen begin with the decay'd Trees, if there be any, leaving the beſt and moſt flouriſhing till the laſt, becauſe they can get no Damage in ſtanding a little longer; and the others which have begun to decay, will be periſhing every Day more and more.

More Things enter into the Conſideration in the Article of felling the Oak than any other Timber; as the ſeparating of the Bark for the Tanners, and the like. The beſt Seaſon is the latter End of April, which favours the Separation of the Bark; it then riſing freely and eaſily.

At this Seaſon the Trees being mark'd out that are to be felled, the firſt Thing to be done is to cut off ſuch Arms as may damage the Trunk in the fall. The Manner of doing this is, by beginning below cloſe to the Trunk: when they have thus cut the Arm about a ſixth Part through, they begin at the Top near the Trunk alſo, and when they come near meeting the other cutting, the Arm falls off without ſpliting.

When the Branches that may be hurtful in the Fall are thus removed, they are to go to work upon the Trunk, cutting it down as near as poſſible to the Ground, becauſe the Length of the Timber is a very great Article in its Value, beſide the adding to its Quantity.

When the Oak is down, its Trunk is to be ſtrip'd of the Bark, which will come off freely at this Seaſon, becauſe the Sap is full and flowing; as the Bark is taken off, ſet it up in ſuch a Manner as it may dry beſt. After this take off the Bark from the Branches that were left on; and ſet it up in like Manner: when this is done, let the Branches be cut off; and then cut it into Lengths for Sale.

It is a Cuſtom in many Places to take off the Barks of Oak Trees as they are ſtanding, a Year or more before they are felled. This is done to give a Strength and Firmneſs to the Timber, and is called in thoſe Places a ſeaſoning of it: but notwithſtanding what has been ſaid in favour of this Practice, I have never been able to find from the Accounts of thoſe who have try'd, that it is of any Uſe.

CHAP. XVI.

Of the ſeaſoning Oak, and judging of the Timber.

THE Wood being thus felled and cut out, the next Conſideration is the ſeaſoning of it, which is done ſeveral Ways; but all of them require Time. Green Oak is fit for very few Purpoſes; and a great deal of its Value in many Caſes depends upon the ſeaſoning.

The plaineſt and moſt familiar Method is to truſt to Time only, taking Care to prevent Accidents in the mean while. Thus let the Timber, cut as before directed, be laid up till dry in a careful Manner. Let it be taken off the Ground at a dry Time, and laid up in an airy Place, but out of the Reach of the Sun, and defended from the Winds, both which crack it in the drying. Let Blocks be put between the ſeveral Pieces, to give Paſſage to the Air. If this be omitted, they grow moiſt and mouldy, or breed Toadſtools. In this Manner Time will take a proper Effect, the Timber will ſhrink gradually and regularly, and being thus ſeaſon'd, it will ſtand when it is employ'd in Building, or on other Occaſions.

Another Way of ſeaſoning Oak Timber is by burying it for ſome Time under Ground: but this

this muſt be done in a dry Soil, otherwiſe it will require more ſeaſoning when it comes out than it did when it was put in.

The beſt Method of all for many Purpoſes, and particularly thoſe which require the beſt ſeaſon'd Timber, is that we learn'd of the VENETIANS, which is called the Water ſeaſoning. This is done by ſinking the Timber under Water; and no Way is ſo good to prevent its ſpliting. The VENETIANS from whom we learn'd this, keep the Timber for their Sea Service two or three Years under Water before they uſe it, and then it ſtands firmly.

The Water ſeaſoning is commonly done in ENGLAND in this Manner. When the Oak is cut into Boards, or Pieces, they ſink it under River Water for fourteen or fifteen Days. Then they take it out, and lay it up carefully to dry in a cool airy Place, as directed in piling up the freſh Timber; preſerving it from Winds and Sun, but leaving the Air free Paſſage amongſt it.

Oak that is cleft is not ſo apt to ſplit and crack as ſuch as is entire: and round Pieces are always more ready to crack than ſuch as are ſquared. Theſe are ſtanding Rules, and the Workman is to conduct himſelf in his Choice accordingly: Pieces that are bored through are found ſeldom to ſplit. In general the more the Oak is in its natural Condition, the more liable it is to ſplit; and the more it has been cut and wrought, the leſs.

Burning the Ends of Poſts of Oak that are to be let into the Ground, has been accounted an excellent Method to preſerve them a long Time; and ſome have carried this Practice ſo far, as to burn the Ends ſo deep as to impair their Strength. It is at preſent much diſputed by thoſe who pretend Experience on their Side, whether this Practice be of any Uſe at all. If not, 'tis a great deal of Trouble thrown away.

This burning naturally preſerves that Part of the Poſt from the Worms by which it is ſubject to be gnaw'd under Ground; and the DUTCH to prevent the ſame Accident under Water, cover over their Piles and Ship Bottoms with Pitch and Tar; on which they ſprinkle Sea Sand with Powder of Sea Shells among it, and Flakes of Iron, ſuch as fly off in the hammering.

In the Choice of Oak Timber, the Purchaſer ſhould examine the Weight and the Grain, the heavieſt Timber in this Kind is always the beſt for Purpoſes that require great Strength and Soundneſs; and the ſmoother and evener the Grain, the better for moſt Occaſions. Oak is not to be truſted in any nice Works, till it has been well ſeaſon'd: and that from full grown Trees, is preferable to ſuch as has been cut from ſmaller. But when the Tree has ſtood beyond its Time, the Wood becomes ſomewhat brittle; this is the firſt Tendency in Oak to decay.

CHAP. XVII.

Of judging of Oak as it ſtands.

THIS is an Article of great Conſequence very frequently, and nothing is ſo difficult: it is a common Thing to purchaſe Trees ſtanding; and in Oak 'tis of great Importance to be able to gueſs at their Value. Where all is good, nothing would be ſo eaſy, for the Queſtion might be anſwer'd by meaſuring, inſtead of gueſſing, but nothing is ſo capable of deceiveing as a Tree while it ſtands. There may be many Infirmities which 'tis impoſſible to diſcover till it is down; and which then greatly leſſen the Value. Such as may be diſcover'd we ſhall point out; as alſo the Signs of Decay.

In the firſt Place, if the Head of the Tree be in any Part dead, 'tis a ſhrewd Sign that there are more Faults in the Body: in this Caſe it is a very good Method to bore into the Trunk with a ſmall Piercer made Auger Faſhion, and obſerve the Condition of what it draws out.

If in any Tree there be a ſwelling Vein perceiv'd riſing above the Level of the reſt of the Tree, and cover'd by the Bark, it is a Sign all is not well within. When this Vein twiſts about in the Manner of a Stalk of Ivy, it is worſt of all; and ſeldom is ſeen but where the Heart of the Trunk is rotten.

Finally, another very good Method of judging is, to open the Earth about the Roots; and examine in what Condition they appear. If they are freſh, ſound, and full of Juice, it is a Sign all is well above: but on the contrary, when many of them are found decay'd without any viſible Cauſe in the Ground; when ſome of them are rotten, brittle and mouldy, all is wrong in the Body of the Tree. This is a Part not ſo much attended to, but a Decay here is a more fatal Sign than the Deadneſs of a Part of the Head.

Upon the whole, a great deal is to be judg'd by the general Aſpect, and that much more by thoſe who are accuſtom'd to theſe Things than by Strangers. There is a Look of Health in a Tree that is perfectly well and ſound, which no other perfectly has. And tho' People who ſhould be Judges are often deceived, yet it is their want of Obſervation, or their want of Knowledge that often leads them to it. There will be Faults which no Perſon whatſoever can diſcover till they are ſeen in cutting through the Tree; but the greater Part of thoſe which debaſe the Value, are not of this Kind: they may be gueſs'd at leaſt, if not certainly known, from ſome one or another of theſe Marks on a careful Inſpection.

CHAP.

CHAP. XVIII.

Of the Elm; its Kinds, and proper Soil and Situation.

NEXT to the Oak the Elm is the moſt univerſal of the English Timber Trees. It is of all Trees the moſt common in many Parts of the Kingdom in Hedge Rows; and is thence the moſt familiar to the Eye of all the Kinds.

The Elm is not a Tree remarkable either for Flowers or Fruit. Both are inconſiderable. The firſt ſcarce at all regarded; and the other rarely minded, unleſs where fallen in Heaps under the Tree. The Flower is little and hollow, with ſome Threads in the middle; and the Fruit which comes after it is a flat leafy Caſe, having in the middle a longiſh Seed Veſſel, ſomewhat like a Pear in Shape, with one Seed.

We have no leſs than five Kinds of Elm common in one or other of our Plantations. Some in Hedge Rows, others in Coppices; and ſome in Avenues and Plantations intended for Ornament. It is of great Importance to the Planter, who conſiders theſe Things with regard to the Profits that may ariſe from them, to have a perfect Knowledge of theſe Diſtinctions; and to chuſe the proper Kinds according to his ſeveral Occaſions. One being preferable on ſome, and others on the others.

The five Kinds of Elm are theſe. 1. The common Elm. This is a tall well growing Tree, with broad rough Leaves. 2. The narrow leav'd Elm; this has ſmall and narrow Leaves, and is called by ſome by way of Diſtinction, the English Elm. 3. The Dutch Elm; this has broader Leaves than the common Elm, and as rough as they. 4. The Witch Elm; which has very ſmall and broad Leaves: and, fifthly, the broadeſt leav'd Kind of all, which is called the Witch Hazel.

All theſe ſucceed extreamly well in our Plantations, but it does not appear from the earlieſt Accounts that any one of them is a Native of the Kingdom. Some of them are taken into Gardens for Hedges; and the Nurſery Men who ſpoil many a handſome Tree for Curioſity, have found the Way to get them with yellow and white, variegated, or as they call them, ſtriped Leaves.

The common Elm, the narrow leav'd Elm, and Dutch Elm, are beſt for ordinary Plantations; the two others, namely, the witch Elm, and witch Hazel, do beſt in Woods. Theſe two grow very well among other Trees; but the other Kinds, though they ſucceed extreamly well elſewhere, and will bear to be planted in Rows very near one another, do not thrive in Woods.

This is a ſingular Obſervation, but it is not difficult to be explain'd. The Elm, when intended for long Growth, muſt have free Air, and a large Scope for its Roots where there is Plenty of Nouriſhment. For this Reaſon ſeveral Elms ſtanding very cloſe to one another thrive, becauſe they are yet open to the free Paſſage of the Air from each Side, which they are not when choaked up every Way in Woods: and their Roots here can ſpread to a Diſtance under the Turf, and find Nouriſhment in Abundance, which they cannot do in Woods, where every Inch of the Ground is full of Roots of other Trees.

The Elm is very hardy, and full of Life: but it requires a great deal of Nouriſhment; ſcarce any Tree more. It will ſend out its Roots a vaſt Way to ſearch for it, but then it muſt be ſupplied in Plenty in thoſe Places. Thus it is ſupplied where other Trees are not planted about it, but not where they are. This is the ſole Reaſon why the Elm ſucceeds excellently in Hedge Rows and Avenues, but not at all among the other Trees of a Wood. Far from hurting one another by being planted cloſe in Avenues or Hedges, they are found to thrive the better: for they thus defend one another from Winds, and are obſerv'd to grow ſtraiter and taller in theſe Places, than where they ſtand ſingle.

Though the Elm will grow any where, yet it requires a good Soil and Situation to thrive. When too much expos'd, as upon hilly Lands, it does not proſper any Thing nearly as in lower Grounds, neither will it ſucceed to the Planters Wiſhes in a hot dry Soil. It will live in ſandy or gravelly Grounds, but he knows little of his own Intereſt who plants it there. In ſome Places the Elm has been obſerv'd to grow very poorly, though the Soil was good, but there has been a bad Bottom.

The Soil the Elm loves, and in which it proſpers to the utmoſt, is good rich Mould; and the Situation that moſt favours it, is a level and ſomewhat low Ground, for it loves Moiſture. In the Hedge Rows of ſuch Lands Elms will yield a vaſt Advantage. They will often grow very well under the Advantage of that Situation, even where the Soil is not ſuch as beſt ſuits with them. The Huſbandman may know by the Growth of his Neighbours Elms, whether they be a proper Plantation for his own Grounds; for where they grow tall and ſtrait, they alſo grow quick; and, on the contrary, where they are low, ſtubbed, and ill-ſhap'd, they grow ſlow: this is his great Conſideration. For in one Place he will have good Timber in a little Time, and in the other, he will, after a great while, have much leſs in Quantity, and that from its ill Growth alſo, leſs Value.

Let him therefore plant Elms only in favourable Soils, and good Situations; in Places not expos'd, in light Earth, and where there is Moiſture. There are Trees enough for his hilly Places, and dry Soils, as will be ſeen hereafter; for in ſuch the Elm will never thrive as in others.

In Choice of the Kind, let him prefer the English Elm, either of the broad or narrow leav'd Kind to the Dutch. In this I ſhall ſeem particular, contradicting the vulgar Practice. It is ſuppoſed the Dutch Elm thrives quicker, but this is an Error. For the ten or dozen firſt Years the Dutch Elm will out-grow the English, but that is all. I have ſeen two planted together of equal Size, and equally thriving Trees: for ten or twelve Years the Dutch has thus out-grown the English; but after that it grows more ſlowly; and, on the contrary,

contrary, the ENGLISH more quick: by eighteen Years old the ENGLISH Elm had greatly the better of the DUTCH; and at this Time 1748, both being of three and twenty Years Growth, the ENGLISH Elm exceeds it by a vaſt deal.

The Planter may here take this Leſſon, that if at any Time he have a Mind to cut the Elm while ſmall, the DUTCH is beſt, but this is not the common Deſign. When rais'd for Timber, the ENGLISH has the Preference: and there is another great Difference, the Timber of the ENGLISH Elm is much better.

If any one is determined to have the larger Elm in Coppices, though I have already obſerved the witch Elm and witch Hazel are fitteſt for that Uſe, he muſt plant them only at the Edges of the Piece, for they will not do in the Middle; and for this Purpoſe the DUTCH Elm is better than the ENGLISH, for the Reaſon given already; which is, that in twelve or fourteen Years, the common Time of Growth of a Coppice Plantation, it will be larger than an ENGLISH one.

The ENGLISH Elms are altogether to be prefer'd for Timber Trees, and of the two Kinds of them the careful Planter is to chuſe the broad leaved for the richer and moiſter Soils, and the narrow leaved Kind for the dryer and poorer. If he will plant Elms in his hilly Hedge Rows, the narrow leav'd Sort will grow better than the other. For Parks and Avenues the broad leav'd Elm is to be prefer'd, becauſe it is the more beautiful, and naturally the more regularly growing Tree.

CHAP. XIX.

Of the Propagation of the Elm.

THE Propagation of the Elm is exceedingly eaſy, for it may be rais'd any Way that any other Tree whatſoever can. It will grow from freſh Poles of it ſtuck into the Earth, at a proper Seaſon, in the Manner of the Willow; and may be rais'd in great Abundance, by burying a large Piece of a freſh Branch in the Ground, at a proper Time of the Year, and in a good Place.

It may be rais'd in the Nurſery either from Seed or by Suckers, and it bears tranſplanting perfectly well; ſo that the Planter may take his Choice of any of the following Ways.

If he uſe a Nurſery let it be on a Piece of even Ground well fenc'd; and order'd as before directed. Many ſay the Elm bears no Seed, and ſome have written ſo, but that is a ſtrange Error. Whoever walks in an Avenue of well-grown and thriving Elms in APRIL, will find the Ground cover'd with the Seeds of the Trees, in thoſe thin leafy Caſes I have deſcribed as holding them. To get his Seed let him mark out a very well-growing Tree, and watch the falling of theſe Parts. Let a Quantity of them be gathered, and directly ſown in the Nurſery in Rows, at a ſmall Diſtance and very ſhallow, the Earth being only juſt raked over them.

They will ſhoot in great Abundance; and are after a little Time to be thinn'd: the Ground is then be kept clear from Weeds; and at two Years Growth they are to be removed into another Part of the Nurſery, planting them at two Foot Diſtance, in Rows four Foot aſunder: and here they are to be kept till they are of ſix or eight Years Growth, at which Time they will be fit to tranſplant into the Places where they are to remain.

The Nurſery muſt be, all this Time, kept clear from Weeds, and the Ground dug every Spring between the Rows, which will greatly aſſiſt their Growth: and from Time to Time they are to be prun'd up, cutting off all the large ſtraggling Branches, that would hinder their upright Growth; in which both the Beauty and Value of an Elm conſiſt. The Elm is, while young, to be prun'd much cloſer than the Oak; but even this is not to be wholly deprived of its Shoots; for a young naked Trunk, with only a Twig at the Head, will never riſe to be a fine Tree. Some ſmall Shoots muſt be left on, otherwiſe the Sap all runs up, none ſtaying to encreaſe the Trunk, and the ſmall Top that it has left is too heavy for the Support of its weak Stem: this bows down therefore, and the Tree will grow for ever crooked.

The common Way of raiſing the Elm is from Sets, which grow in vaſt Abundance from the Roots of the old Trees in Hedge Rows, where the Soil is favourable. Poor People take theſe up in many Places, and ſell them to the Nurſery-men, who thence raiſe young Elms for Sale. The beſt Time of removing theſe Suckers is toward the End of OCTOBER; but the Trees thus rais'd are ſeldom ſo good. The Way from Seed is very eaſy. And the Plants ſown in Spring will be up by the Beginning of AUGUST, and will ſtand the Winter of themſelves, though if a little looſe Straw, or other ſuch Matter, be ſcattered over them by Way of Defence, they will ſucceed the better.

Thoſe who would raiſe Elms from Stakes ſhould cut them about ſix Foot long, and of the Thickneſs of a Child's Wriſt, ſtriking them off at the Bottom by one ſlanting Stroke. Theſe being ſtuck down in a moiſt and mellow Earth in Spring, will ſhoot very vigorouſly, but irregularly. This is to be done early in the Seaſon, and in a rich and ſomewhat damp Soil.

In like Manner thoſe who raiſe Elms by burying the Branches, or larger Boughs, or the Trunk of ſome ſmall Tree, muſt chuſe a good Earth, where there is ſome Moiſture, and the Spring Seaſon. In this Earth they are to dig Trenches of a Foot deep, and to lay in them a Piece of ſix, eight, or ten Foot long, of a large Bough, or of the ſmall Trunk of an Elm. They are to cover this up with the Earth taken out of the Trench, and watering it once or twice leave it to Nature. There will riſe many young Shoots in a few Months, from every Part of the buried Wood. But theſe are Methods to be uſed only to ſuit particular Purpoſes.

Thoſe who would ſpare the Trouble of ſowing the Elm, by taking up wild Suckers, had better do this themſelves, than purchaſe them of others; and better prepare for the getting them than take them as they happen to riſe.

The Way to prepare for them is this. Lay bare ſome of the large Roots of a tall and thrive-

ing Elm, and chop them with an Axe one fourth Part through in ſeveral Places. Put a little Piece of Wood by way of Wedge, or a ſmall Stone, into every Nick, thus made with the Axe, and then cover the Roots up again with Mould about three Inches thick. There will riſe from each of theſe Nicks a great Number of Suckers, which at two or three Years Growth may be taken off and tranſplanted.

Another Way of obtaining Suckers in Plenty is this. Dig a ſtrait Trench at ſome Diſtance from an Elm, and the Roots having been wounded by this, and being laid bare will ſend up a vaſt Quantity of Suckers. Theſe are to be cut off from the old Roots, and tranſplanted at two Years Growth, and they ſeldom fail to produce good Trees.

We have mentioned theſe ſeveral Methods of propagating the Elm, to ſhew how eaſy it is to raiſe a Supply for Plantation: but there remains yet one other Way to be nam'd, that is, by Layers; for, to go regularly to work, the Way is to raiſe the young Elms either from Seed or by this Way; they being, by one or other of theſe Methods, more certain of Growth when tranſplanted, and of being ſtrait and well-bodied Trees than any other. To raiſe a Supply of Elms by Layers, the regular and certain Method is this.

Let a ſmall Piece of Ground be dreſs'd carefully for receiving the Roots and Stumps of ſome Elms, which are to furniſh Shoots for Layers: theſe Roots, with their Stumps, are called the Stools.

The Soil of this Piece of Ground ſhould be light, but with ſome Degree of Moiſture; and it ſhould be trench'd, and a little well rotted Dung buried in it. When this Ground has been clear'd from all Roots of Weeds, and laid level, the Plants muſt be let into it at about eight Foot Diſtance. The Seaſon for this is Autumn, and being a little watered, and the Ground dug now and then about them, they will, the next Spring, make a great many vigorous Shoots.

Theſe Shoots are to be laid, and the proper Time for that is when they are of about two Years Growth.

At this Age, in the Middle of February, they are to be laid in this Manner. Each Shoot is to be ſlit a little Way, and then buried under the Mould. Five or ſix Inches Depth of Earth is to be laid over the Shoot; and its Top is to riſe a Foot out of the Ground.

When all the Shoots are laid the whole Stool is to be well watered: and this is to be repeated at Times when it ſhall appear moſt neceſſary, during the Summer; and by this Means, the Elm being a very lively and vigorous Tree, theſe Shoots will all have taken Root by the following Autumn, at which Time, when the Leaves are fallen, they are to be taken off and planted in the Nurſery, at a Foot and half Diſtance, in Rows three Foot aſunder; where they may ſtand till they are of a Size to remove into the proper Places.

This is the whole Trouble of that Practice, call'd by the Gardiners and Nurſery-men, laying; and it is idle for any one who intends to plant many Elms, not to do it for himſelf: a few Stools thus planted will yield, every Year, a great Number of young Elms, with ſcarce any Trouble.

If at any Time a Shoot will not lie readily, it is to be pegg'd down with a wooden Hook or two.

Inſtead of ſlitting the Shoot ſome twiſt it; and in other Caſes a Wire is tied tight round it, and Holes pierc'd through and through with an Awl; or the Shoot is lightly cut round. Any of theſe Methods will do, for all that is needful is to give the Shoot a Tendency to puſh out a Root at the Place where it is laid: and when that is done, and the Roots have ſome Strength, it is to be cut off from the Stool, and tranſplanted into the Nurſery, to arrive there at the proper Growth for its laſt Removal.

Though early in the Spring be the beſt Seaſon for laying the Elm Shoots, it may be done with Succeſs in Autumn: and although Spring is preferable for the Elm and other very vigorous and quick-ſhooting Trees, yet for others the End of October is better; becauſe they have then the whole Winter to prepare for rooting, before they are called on by the Warmth of Spring to ſhoot out Leaves and Branches.

That there is ſome Sap riſing all the Time from October to the March following, which is the Seaſon when the Spring Shoots are preparing, is plain from this, that there is a continual Waſte of Sap from the live Branches of Trees at that Time: for if they be cut off, and the cut End ſeal'd up, that no Moiſture gets out there, ſtill there will be a large Quantity, conſidering the Seaſon, evaporated; and the Branches will grow dry and loſe their Weight. Doubtleſs the ſame happens while they are on the Tree, as is thus found when cut off, and there muſt be a Supply for this from the Root.

Now as it is plain there is ſome Sap ſent into the Shoots at this Seaſon, and that it does not force out Buds or Leaves, nothing is more natural than that it ſhould ſpend itſelf in ſending little Roots from the wounded Part of the Shoot, which is quiet and warm under Ground.

This is a ſubſtantial Reaſon for laying many Trees in Autumn; but for ſuch as the Elm that thrives ſo freely, and will ſend out Roots at any Time, the Spring is early enough. I have named the different Seaſons, and explained the Reaſon here for the Sake of the Huſbandman's general Knowledge. Such Trees as do not root freely in the Layers, may be beſt laid in October; the others in Spring.

Having thus once delivered, at large, the Method of raiſing a Tree by Layers, it will be underſtood when only mentioned on ſucceeding Occaſions. It has been judg'd right therefore to be the longer in theſe firſt Chapters upon the Propagation of Foreſt Trees, that we may be the ſhorter on others.

Some have pretended to deny the Riſe of any Sap in Winter: and theſe might very well object to the laying Trees in Autumn; for if no Sap roſe they would be in the Condition of dead Sticks at that Time, and their buried Part would be in Danger of rotting. But the contrary moſt evidently appears. It is found by Trial that the Holm Oak, and the Cedar of Lebanon will grow by grafting on the common Oak, and on the

the Larch Tree. And although the Oak drops its Leaves in Autumn, the Holm Oak grafted on it keeps green all Winter; and juſt the ſame happens in the other Caſe; for though the Larch Tree drops its Leaves in Autumn, the Cedar being an ever-green like the Holm Oak, keeps its Leaves when grafted on it. It is very plain therefore, that ſome Sap ariſes from the Oak, and the Larch Tree all Winter, otherwiſe theſe Grafts could not keep their Leaves; for they could not keep them without Sap, and they have no other Supply. Leſs Sap ſatisfies Evergreens, becauſe they evaporate leſs, but ſtill it is plain there muſt be ſome.

We would have the Farmer underſtand every Thing he is adviſed to practiſe. And with that Deſign this Matter is ſo carefully explain'd to him. He ſees plainly that ſome Sap riſes in all Trees in Winter: therefore when we ſhall on any future Occaſion direct the raiſing a Tree from Layers; and order it to be done in October, let him not ſuppoſe it an Error, or a careleſs Direction; for there are many that will ſucceed beſt that Way, though the Elm does better in Spring.

The Huſbandman has here before him the ſeveral Methods by which the Elm may be propagated. But of all theſe the two which are preferable, are from Seed or by Layers; and in his Choice between theſe, he is to be determin'd from his own particular Circumſtances and Deſigns. If he intend a Plantation of Elms to be made at once, and ſhall not think of repeating that Work, the beſt Way is raiſing them from Seed: but if he intend to continue from time to time planting, he is to prefer that by Layers. For the Seedlings are a Stock for once; but the Stools for laying being once prepared, will afford a freſh Supply every Year for his Life.

If the Farmer at any Time want to ſet a few Elms only, it is not needful he ſhould be at the Trouble of either of theſe Methods: but his beſt Way will be to take up Suckers from the Hedge Rows, chuſing the ſtraiteſt and moſt promiſing.

CHAP. XX.

Of the Uſes of the Elm in Plantations.

THE Elm is a valuable and uſeful Tree, both for the Field and Garden: and none is more to be eſteem'd for Plantations, where the Eye is to be pleaſed, as well as the Eſtate improved by them.

No Tree is ſo good as the Elm for Avenues and Walks, becauſe, with proper Care, none grows ſo upright and regular; and none will, in ſo ſhort a Time, reach ſo conſiderable a Height.

No Tree is better for Hedge Rows, when the Soil and Situation are ſuited: for by its upright and regular Growth, it is an Ornament to an Eſtate; and its Branches not ſpreading too wide, eſpecially in the uſual Way of lopping in Hedge Rows, it does not ſhade too much of the Crop in the Field; and yet it is leafy, and affords a ſufficient Shade for Cattle.

In Parks alſo, the Elm makes a very beautiful Appearance in Clumps, or ſingly: but for this Purpoſe 'tis beſt not to lop it up ſo cloſe, but to leave ſome large Branches; or from twenty Foot upwards to ſuffer it to ſpread as Nature pleaſes. In this Way Elms will ſtand many Years, and look very beautiful, but they are apt to grow hollow: the Verdure will often keep freſh when the whole Heart of the Tree is gone; nay, when nothing remains but a Shell of Bark. But this is not wonderful, for the Bark conveys up the Sap.

The young Shoots of the Elm are a very acceptable Food for Cattle; and they may often be cut for this Purpoſe to the great Profit of the Farmer; when other Fodder is expenſive.

The Loppings are very good Wood for Fuel; and an excellent Kind of Charcoal is made of the Branches.

Theſe are the ordinary Uſes of the Elm in the Field; excluſive of its Timber. About Houſes it is valuable becauſe it is very pliant; and may be made to grow any Way.

It is excellent to plant by way of Defence from Winds. For, if left to ſpread its own Way; its growing cloſe, and its great Number of Branches, are an excellent Shelter; but if cut and train'd up, it may be raiſed into a Hedge of forty Foot or more in Height, and of ſuch a Compactneſs, as to keep off every Blaſt from the Dwelling.

But Caution muſt be taken that Elms be not for this Purpoſe planted too near the Garden, for they will rob the Fruit Trees of their Nouriſhment, and ſpoil the Beauty of both Graſs and Gravel. No Tree ſpreads its Roots ſo wide as the Elm, and theſe will therefore interfere with thoſe of the Wall Trees, and deprive them of their Nouriſhment; and as no Tree in the World is ſo apt to ſend up its Suckers from the Roots; theſe will riſe every where among the Graſs, and through the Gravel, being an eternal Plague to the Gardiner, and continually defacing the Beauty of the Walks.

A vaſt Advantage of the Elm about Houſes, is alſo that it may be tranſplanted when very large; no Tree bearing this ſo well. But let the Planter in that Way receive this Advice, always to get his large Trees from a Nurſery; becauſe having been there prepared for tranſplanting, they will riſe with a good Root; whereas thoſe from Hedge Rows often fail when taken up at any Size from the Irregularity of the ſpreading.

In this Place alſo, it may be proper to inſert the neceſſary Cautions about removing thoſe Trees for the laſt Time, or to the Places where they are finally to ſtand. Now, on this Occaſion, whether they be very large, or of the common planting Size, which is at ſeven or eight Years Growth: this muſt be done in the Beginning of October; their Heads muſt be leſſen'd, but the leading Shoot muſt not be taken off; nor muſt the other Branches be cut too cloſe. Their Roots muſt not be buried too deep; and eſpecially if the Soil be moiſt. It is better in this Caſe to plant them ſhallow, and raiſe a Bank or Hill about them. When this is done, they are to be ſtaked as directed for the Oak;

Oak, and by theſe Means there will ſcarce ever a ſingle Tree fail either in the Garden or Field.

The beſt Seaſon for lopping the Elm is about the Middle of JANUARY; and the oftener this is repeated, the taller the Tree will grow. The Side Boughs are to be cut off freely in theſe Loppings, but the Tops muſt be ſpared: when they are cut too near, they frequently let in Wet, to the Deſtruction of the Tree. In SPAIN they have Plantations of Elms many Leagues in Length, which are kept conſtantly and frequently lopped, and by their even Trunk, great Height and buſhy Tops, make a noble Appearance.

CHAP. XXI.

Of the Value of the Elm in Timber.

WE have conſider'd the Elm in a Variety of Uſes while ſtanding, we are now to examine into its Nature and Value as Timber.

The beſt Seaſon for felling the Timber Elm is in the Beginning of DECEMBER. No Tree is ſo vigorous as this; and therefore the fit Seaſon for cutting it down is to be conſider'd in a particular Manner; for to give the greateſt Value to the Timber, the Sap muſt be as much as poſſible at reſt when it is cut: and this is the Seaſon when it is in that State.

As to the Kinds of Elm for Timber, we have obſerv'd already, that the ENGLISH Elm is better than the DUTCH, for the Wood is ſounder. Of the two common ENGLISH Kinds rais'd for Timber, the Difference is this, the broad leav'd Elm affords an evener grain'd Plank; but the Timber of the narrow leav'd Kind is harder.

Though theſe are the only two we uſually raiſe for Size, we need not be ty'd down to them, for the witch Elm, which we commonly confine to the Coppice, will afford an excellent Timber: this is not at all inferior to that of the common Elm, and is of the ſmooth grain'd Sort, or more like that of the broad, than the narrow leav'd Kind.

The witch Elm requires the dampeſt Soil of any of the Kinds; but in ſuch Ground it will out-grow the common Elm. It is this Quickneſs of Growth that has given it the Preference above the other for a Coppice Shrub. But it will in ſuch Plantation riſe to an excellent Tree, fully equalling the Elm in Bigneſs, and in Value.

The Planter will do well to conſider this, and to raiſe Supplies of this as well as the other Kinds, and to ſet it always in the dampeſt Places where his Elms are to ſtand. For this Purpoſe he ſhould ſow the Seeds of each Kind; and diſpoſe them properly, which will vaſtly increaſe his Profits; or if he raiſe them from Layers, he ſhould have two or three Stools of each Sort; ſo that he may take off his Layers from Kinds fitted to the Soil, which can never be done if he buys them.

The Elm Timber is an exceeding ſtrong and ſound Wood; and it is very durable either in Places where it is kept always wet, or where it is always dry: but it does not bear ſudden Changes from one Condition to the other. It endures a vaſt while in Water Pipes, which are always wet and under Ground, and in many of the common Uſes where it is never wetted at all, 'tis in a Manner everlaſting. Its Toughneſs recommends it to the Wheelrights and Millrights: and it is very uſeful for Dreſſers and chopping Blocks, becauſe it will not break away in Chips.

There is a vaſt Difference between Elm Timber cut in the Middle of Winter, and that at other leſs favourable Times. The Trees are in felling to be cut off as cloſe as poſſible to the Ground; and Care muſt be taken about the Fall, that they are not hurt by their own Boughs, or Things in their Way, for they come down with a great Weight by reaſon of their Tallneſs.

It is made by ſome a great Objection to the Elm, that it is apt, as before obſerv'd, to be hollow: but this may in a great Meaſure be prevented, by obſerving the Directions already laid down, in the Articles of the laſt Removal and the Lopping. Twenty Elms become hollow by bad Management, for one that is ſo from Nature. The common Occaſion of it is, the cutting the leading Shoot; or ſome upright Branch of the Head; or ſome nearly upright Branch elſewhere: theſe let in the Wet at the Wound, and the Decay which begins there, runs down to the Bottom of the Tree.

When a Branch has thus injudiciouſly been taken off, which endangers the Tree, the Method to prevent that Miſchief is to cut it off again cloſe to the Trunk, and cover the Wound with Lead, or Oil Cloth.

As the Elm ſo ill bears cutting off its upright Branches, it does but very badly take the topping for a Pollard. 'Tis indeed one of the worſt Trees for this Uſe: but ſome will cut it in that Manner. In this Caſe many die in the Operation; and the reſt, though they ſeem to bear it at firſt, commonly grow hollow afterwards, and decay entirely.

When the Farmer intends to uſe the Shoots and Branches of the Elm as Fodder for his Cattle, he ſhould cut them about AUGUST, and let the Leaves dry on them. Theſe will keep till Winter, and the Cattle will eat them rather than almoſt any other Food, and thrive upon them extreamly. Hogs will eat them green, and fatten upon them very quickly.

People who are fond of relating ſtrange Stories, have aſſerted that Elms will grow from Chips of the dry Wood. This is not true, but what gave riſe to it is a very familiar Obſervation. Elms are often removed ſoon after they are felled; and ſometimes when they have ſhot out from the Knots, as they will do as they lie on the Ground. When theſe are ſquared for Uſe, thoſe knotty Parts being trodden into the Ground by the Workmen, will ſhoot: but the reſt of the Story is not true.

The common broad leav'd Elm in a rich and ſomewhat moiſt Soil, will grow to a great Bigneſs. There have been ſeen whole Rows of them in Hedges, that were three Foot ſquare for forty Foot in Height; and there are authentick and unqueſtionable Accounts of an Elm in

OXFORDSHIRE, which near the Ground was ſix Yards in Diameter. Dr. PLOT who gives us this Account, mentions a witch Elm very nearly of the ſame Bigneſs: he ſays it was at the lower End ſeventeen Yards in Circumference, forty Yards high, and contain'd near a Hundred Ton of Timber.

The Elm is not ſo tedious in its Growth as the Oak, and the Demand for its Timber is very conſiderable, though the Price be but moderate: the Quantity uſed for Water Pipes alone is ſurprizing. There is therefore great Encouragement for the Huſbandman to plant it. 'Tis eaſily done, the Expence almoſt nothing: the Ground it takes up in Hedge Rows in the ſame Manner nearly nothing, and it grows quick, and may be cut down at any Bigneſs to conſiderable Profit.

CHAP. XXII.

Of the Aſh, its proper Soil and Situation.

THE Aſh is a tall and ſtout Tree when ſuffer'd to grow freely. Its Leaves are every one compoſed of ſeveral ſmaller, which ſtand on each Side a Stalk with an odd one at the End. The Flowers are ſmall and inconſiderable. They conſiſt only of a few ſhort Threads. The Fruit grows in other Parts of the Tree, is what we call the Aſh Key, hanging in Bunches.

Though we have ſeveral Kinds of the Elm, there is but one Sort of Aſh wild in ENGLAND, or fit to be cultivated in Hedges or other Plantations for its Timber. The Gardiners have found the Way to ſtain its Leaves, and then call it the variegated Aſh. The flowering Aſh, and ſome other Kinds, are alſo kept there for Beauty; but with theſe the Huſbandman has nothing to do. There is one from NEW ENGLAND with ſharp pointed Leaves, and another from CAROLINA with broad Keys. The ITALIAN Aſh which affords Manna, is alſo diſtinguiſh'd by having rounder Leaves; but with theſe he whoſe Intent is to raiſe Timber has no Concern; the common ENGLISH Aſh is his only Kind.

The natural and favourite Soil of the Aſh is, a light and rich Mould, but it will grow any where: we find it in ſandy Ground thriving very tolerably, and alſo on rocky and ſtony; but when it has its own natural Earth about it, the Growth is much quicker. In a good Soil there is ſcarce any Tree that will in leſs Time riſe to ſo conſiderable Value. A Hundred Years is allowed for the Growth of the Oak. The Aſh, on the contrary, will riſe to its utmoſt Perfection in between forty and fifty, when it has been carefully manag'd at firſt, and the Soil ſuits its Growth.

We ſee Aſhes on the moſt barren Mountains, and it is fit the Huſbandman ſhould know they will live on ſuch Places; but they do not thrive there either ſo quickly, or ſo regularly as in better Ground. In general the Planter ſhould be inform'd that it may be proper for him to plant the Aſh on any Soil, and in any Situation, but that he muſt make a right Uſe of it when planted. The Aſh on barren hilly Places, will grow to a very good Coppice Wood; but 'tis not a fit Soil for planting it for large Growth. And in the moſt ſtony Ground, the Aſh may be planted for Pollard, and will yield a good Quantity of Wood in Shrowdings, as well as maintain a firm Trunk to the Height, that is allow'd on thoſe Occaſions: but it is only in the richer Soils, and in more favourable Situations, that it will grow ſpeedily and profitably for Service as Timber.

One Kind of Soil has often been remark'd as favourable to the Growth of the Aſh, which it is a Wonder the Huſbandman has not more obſerv'd, or oftener planted with it, this is the white chalky Soil: many Trees that flouriſh very well on others, will grow but poorly on this; whereas the Aſh, whenever it is ſeen on ſuch a Soil, has a healthy Aſpect; and Experience ſhews thoſe who are concern'd, that it arrives very quick at a valuable Size.

We have adviſed the Huſbandman before, always to look into the Hedge Rows of his Neighbours, before he plants Trees in his own, that he may ſee what Kinds thrive beſt there, and ſuit his own Plantation accordingly. As plain and obvious a Thought as this may be, it is not follow'd. The Work is done at random, and ſucceeds accordingly.

The Huſbandman in KENT and SUSSEX, tho' he ſees the Aſhes in his Neighbours Hedge Rows fair and thriving; and the Elms in the ſame Plantations, crooked, ſtubbed and hollow; yet when he makes his own Hedge, ſets Elms, and they grow hollow and ſtubbed like the others, neglecting the Tree that he ſees thrive ſo admirably.

Cuſtom has been uſed to guide the Huſbandman in ENGLAND, without his ever conſulting his Reaſon, or even Experience. We hope that one good Effect of this Book will be the leading him to uſe both in a proper Manner; and that ſeeing how neceſſary ſuch a Conduct is, and how uſeful, he will for the future try Cuſtom always at their Tribunal, and accept, or reject it, according to their Sentence.

There is one Caution the Huſbandman is always to take with him in the planting the Aſh; that is, that too many of them muſt not be planted in the Hedge Rows of plow'd Lands. The Aſh ſpreads its Roots a great Way, and, if not prevented, its Branches alſo. When this latter is the Caſe, the Drippings from them hurt the Corn, and when the pruning prevents this, ſtill the Roots ſpreading ſo near the Top of the Ground, take the Nouriſhment that ſhould ſupport the Corn: and another Inconvenience ariſing from them is, that they obſtruct the Tillage of the Ground by their Frequency and Toughneſs.

From theſe general Obſervations on the Aſh, the Huſbandman will know where, and in what Manner to plant it in his Grounds; and, when planted, how to manage it to the beſt Advantage.

If he plant it on a bad Soil, and in an expoſed Situation, let him uſe it as Coppice Wood,

covering the Ground either with Aſh alone, or with that and ſome other hardy Kinds, and cutting them down at twelve or fourteen Years Growth, and afterwards every ſeven or eight Years; if he plant the Aſh on a hungry ſtony Soil, let him ſhrowd it at the Height of ten Foot, and keep it as a Pollard. When he has Hedge Rows on good light Land, ſeparating Meadow and Paſture Grounds, let him ſet Aſh plentifully in them; and never let him forget it when the Soil is chalky.

The Aſh does not like the Elm thrive only when it is open every Way to the Air, it is a very good Tree in Woods; and indeed ſo profitable, that they ſhould in very few Caſes be planted, without a large Proportion of this Kind; for it grows no where quicker than among Trees every Way, if the Soil ſuit.

The Soil that agrees worſt of all with the Aſh, is a wet Clay: not but this Tree will bear a great deal of Moiſture, where there is not that Coldneſs and Solidity in the Ground; for we ſee it growing at ſome ſmall Diſtance from Rivers in many Parts of Buckinghamshire, and it thrives no where ſo happily. The Timber when felled, is whiter when it has grown in theſe Places than in any others, but it muſt be confeſſed, it has not altogether that Strength it poſſeſſes in drier Soils.

The Aſh is an Enemy to all ſmaller Growths: and no Tree drains a Land ſo much of its Nouriſhment. If planted too near Gardens, it will ſtarve the Fruit Trees, and hurt every Thing that is propagated within the Reach of the ſpreading of its Roots; and much more whatſoever is within the Drippings of its Branches.

CHAP. XXIII.

Of the Propagation of the Aſh.

THE Aſh is beſt propagated by ſowing the Seeds; and this may be done either in the Places where the Trees are to ſtand, or in a Nurſery from whence they are at a proper Growth to be removed into thoſe Places. The common Cuſtom of Writers is to give one or the other of theſe Methods as the beſt, without any Exception; but we hope to introduce a more reaſonable Practice. It may be moſt convenient to raiſe the young Trees in a Nurſery for ſome Purpoſes; and for others it will be found beſt to ſow them where they are to ſtand. Let the Huſbandman therefore conduct himſelf, not according to any general Direction, but according to the Situation and Deſign of his Plantation.

Let him conſider whether he intend to raiſe his Aſh in Hedge Rows, in Coppices, or Woods, or in Clumps upon expoſed Situations, as in Parks, or on the naked Hills where little elſe of Value will ſtand: for, according to theſe ſeveral Conditions, the Practice he is moſt advantageouſly to follow, will differ.

If his Aſhes be for Hedge Rows, it is beſt to raiſe them in the Nurſery, and to remove them thither by two Tranſplantations: if for Clumps, or for Coppice Woods, 'tis beſt to ſow them on the Spot; but when they are to make a Part of large Woods, the Soil and Situation muſt determine, for on a very good Soil they do beſt by Tranſplantation; but it is beſt raiſing them immediately from Seeds, where the Land is barren, and will not yield them a ſpeedy Nouriſhment when tranſplanted.

The Aſh may be raiſed as the Elm by Layers, but it does not ſucceed ſo well: and the Huſbandman may purchaſe the young Shoots, or Suckers, from thoſe who draw them in the Hedges, but they never riſe to be ſuch fine Trees, nor grow ſo quick, this Experience abundantly confirms, and therefore it is that the Method of raiſing them always from Seed is to be prefer'd; though with this Difference, that ſometimes 'tis beſt to do it on the Spot, ſometimes in the Nurſery.

Which ever of theſe Methods the Circumſtances of the intended Plantation require, the firſt Care is to get a neceſſary Quantity of good Seed. Let the Huſbandman not buy this, for if he does, he is never ſure of its Goodneſs; and 'tis eaſily in his Power to collect it under all poſſible Advantages. Let him ſet his Eye upon a tall, lively and flouriſhing Tree, and watch the ripening of its Keys. When they are thoroughly ripe, let him ſend up a Servant to ſhake the Tree well; and if they don't fall readily this Way, as in ſome Seaſons they will, and in others they will not, let him ſee a Quantity of the Bunches cut off, ſelecting the fulleſt, beſt and largeſt.

The Seeds being thus got, let them be ſown according to the Intent of the Plantation.

If the Trees be intended for Hedge Rows, or for Woods, upon a very favourable Soil, they are to be ſown in a Nurſery; but if for Coppices, in Clumps; for Parks or in Woods, on poor Ground, then on the Places where they are to ſtand.

CHAP. XXIV.

Of raiſing Aſh in a Nurſery.

THE laſt Week in October, which is the Time of the Aſh Keys ripening, let a ſmall Bed of Earth be well dug, and perfectly cleanſed from all Sorts of Weeds. 'Tis beſt to chuſe for this Purpoſe a Piece of Ground that has not been wrought before. The Soil ſhould be light but poor, an ordinary Loam where there is Choice, is preferable to any other: but this is not ſtrictly neceſſary.

When this Earth is well prepared by turning and breaking the Clods, let the Aſh Keys be ſpread for a few Days after their Gathering, upon a Floor of ſome airy Room, where the Sun does not come; and being thus a little dry'd, let them be ſown thick in ſhallow Trenches open'd a-croſs the Bed, at four Inches Diſtance. Let the Earth be drawn over them with a Rake, and the Bed made perfectly level; and ſo leave them to the Courſe of Nature. Nothing will be ſeen of them till about ſeventeen Months after; and they will then riſe in vaſt Plenty along the Places where the Trenches run.

During

During the Time the Seeds lie in the Ground, as well as after they are up, the Bed muſt be kept very free from Weeds; and in the Spring, if there are not frequent Showers the Plants ſhould have a little watering. Sometimes, if the Keys be gathered very ripe, the Ground freſh and good, and the Seaſon particularly favourable, the Aſh Keys will riſe the firſt Spring: but they uſually lie till the ſecond, and we have therefore prepared the Huſbandman to expect it.

The Authors on theſe Subjects who are as ready to abuſe, as they are to borrow, from one another, inſult each other upon the ſuppoſed Errors about the Time of the ſhooting of Aſh Keys; but we are to inform them from Experience, that the Truth may lie on either Side, and thoſe who may write from what they have ſeen who contradict one another; for that it is ſometimes the firſt, and ſometimes the ſecond Spring they ſhoot, but much oftener the latter.

A Nurſery muſt be early prepared to receive the young Trees from this Bed, for the Aſh bears, and requires tranſplanting from the firſt Shoot, earlier than any other Tree whatſoever.

I have always found it moſt beneficial to remove them out of the Seed Beds at ſix Months Growth, one Summer being enough for their ſhooting; and their Roots piercing too quick for deferring it.

Therefore let a larger Piece of Ground be well dug, and clear'd of Weeds, for the Reception of theſe young Trees, the Autumn after their firſt Appearance above Ground. Let Trenches be open'd all over this Ground, at three Foot Diſtance, and let them be deep and wide enough to receive the young Trees, without Injury to their Roots when prepared for them.

The Ground being thus prepared let the young Trees be taken up; but this requires more Care in the Aſh than in many other Kinds; for the ſame Reaſon that this requires to be tranſplanted younger than the others. The Roots muſt be a little looſen'd with a Spade, and then carefully rais'd without breaking. The tap Root, or ſtrait Root that runs down, muſt be cut off at a few Inches Length; the Reſt muſt be left as they are: and the young Trees in this Manner muſt be carefully ſet in the Trenches, at about fifteen Inches Diſtance from one another; and the Earth cloſed and preſs'd down about them.

They are to ſtand in this Nurſery four Years, and then to be removed into the Places where they are to remain: but in order to their growing regularly, ſome Care is to be taken of them while they are in this Nurſery. Weeds muſt be kept thoroughly away, that they may have all the Nouriſhment the Earth can give them; and they muſt be trim'd up every Winter, cutting off the Side Branches.

It will greatly aſſiſt their Growth if the Earth between the Rows be dug up every Spring: and at their firſt bringing into this Nurſery a little Care may be well employed, in ſeeing that they keep upright, and that the Earth be well clos'd about them, which is beſt done by treading it down. Late in the Autumn of their fourth Year, in this ſecond Nurſery, they are to be removed into the Hedge Rows where they are to ſtand; or to be brought into the new Plantations of Foreſts, where a good Hole is to be opened to receive them, and Care taken to ſet them upright and keep them ſo.

The Diſtance for planting them in Hedge Rows, is about five and twenty Foot. In Woods intended for long ſtanding, and a good Growth of Timber, an Aſh may very well and very profitably be planted, every third Tree; and in this Caſe, about nine Foot every Way is a proper Diſtance.

If Aſh would be rais'd alone, as it may in many Places, with great Benefit to the Owner; the beſt Method is to plant them at eight Foot diſtance every Way in the Place, and at the End of the firſt Year, going over the Plantation to cut down every other Tree at ſix Inches from the Root: chuſing the worſt Shoots for this Purpoſe, and leaving the ſtraiteſt and beſt ſtanding.

This thins the Plantation for the preſent to one half, and gives it a double Kind of Growth. Theſe Stems which have thus been cut off, will ſend up many ſtrong Shoots, which will grow into good Poles in five or ſix Years, fit for the Hoop-makers and many other Uſes; and they will thus, at proper Times, yield a Supply of ſmall Aſh in the Manner of a Coppice, very uſeful for this Purpoſe; and all the while the others which were left ſtanding, will be ſhooting up into beautiful and ſtately Trees, which in thirty, forty, or fifty Years, according to the Nature of the Soil, will be of great Value.

The Soil alſo muſt determine whether the whole Number left at this firſt Reduction ſhall ſtand for Timber, or whether they require to be thin'd again; if ſo, let this be done with Diſcretion; and always the worſt taken for cutting down for ſmall Wood, and the talleſt and ſtraiteſt left for Timber.

When the Aſh is removed into the Place where it is to ſtand, ſome of the ſide Branches may be taken off, but the Top is never to be cut. If that be to be done at all they muſt be cut down to the Ground, and ſtand for a Supply of Poles, or at a greater Height for Pollards. For if the Top be once injured, they never make Timber.

There is this Advantage in the Aſh, that where it will not do for one thing, it will for another; and at any Time, when it is ſeen that a Tree will not thrive for Timber, it may be cut off at ſix or eight Inches, and will then ſucceed very well. This may be done at any Time, and the moſt ſickly Aſh will revive upon it.

CHAP. XXV.

Of raiſing Aſh where it is to ſtand.

THERE remain yet ſome other Plantations of the Aſh to be conſidered, theſe are, firſt, when it is to be a Part of Coppice Woods. Second, when it is to be rais'd in Woods on a poor Soil, either entirely of that Kind, or of that mixed with other Trees; and, thirdly, when it is to ſtand in Clumps in Parks, or ſingly upon high and barren Grounds. In all theſe Caſes the beſt Method is to raiſe it where it is to ſtand, but there is a different Way of doing this, in order

order to ſuit it beſt to the ſeveral Circumſtances. We ſhall therefore give the Directions ſingly.

When the Aſh is to make a Part of Coppice Woods, there ſhould always be a double Intent in the Plantation, ſome of the Shoots being to be cut for Poles among the other Coppice Shrubs at the ſeveral Fellings, and ſome to be left to ſtand for Timber.

The Aſh may be let into theſe Coppices either at their firſt Plantation, or after any of the Fellings; and the Method is this.

When the Growth of the other Shrubs is at ſome Height, whether from the firſt Shoot, or any ſubſequent Felling, let the Huſbandman go over them with a Trowel in his Hand, and ſome choice Aſh Keys in his Pocket; the Seaſon for doing this muſt be the End of October, and the Keys juſt gathered, and a little dry'd, as has been already directed for preparing them for the Nurſery. He is to open the Ground with his Trowel, in convenient Places, and let in a few of the Keys. Theſe he is to cover with the Earth taken up, to about half an Inch depth, and then to draw the fallen Leaves over the Place by way of Shelter, and to detain the Moiſture. The Places where he is to introduce theſe is where there is moſt Vacancy, and where the Soil is fineſt, and there is moſt Moiſture if the Situation in general be dry.

Theſe will ſhoot very favourably, and the Autumn or Autumn Twelvemonth following, according as they have ſhot the firſt or ſecond Spring, he is to go over the whole Coppice and examine his young Plants, cutting off thoſe which riſe crooked, within five Inches of the Ground, and leaving the others for Timber Trees.

Thus will he thicken his Coppice in a very eaſy Manner, and that with one of the moſt valuable Trees he can plant in it. Thoſe Aſhes he has cut off will riſe in Cluſters of Poles, to be cut down with the reſt of the Coppice Wood at every felling: the others will grow well, and are to be left ſtanding in ſufficient Number for Timber. When they grow too cloſe the Woodman muſt cut down ſome of them, at the firſt Felling of the Coppice, leaving the Stumps to ſupply the ſmall Growth of Poles for that Purpoſe, in the future Cuttings; and the other Trees to grow up for Timber.

As this is a particular Practice in introducing the Aſh into Coppices, 'tis fit the Huſbandman ſhould know the Reaſon of it.

If the Coppice have been rais'd by planting from the Nurſery, the Aſh will not grow well in it, unleſs the Soil be particularly good. Then as the Aſh requires a Time of tranſplanting from its firſt Beds, different from other Trees, being much earlier, it is beſt to raiſe the Supply of thoſe ſeveral Kinds without it.

'Tis alſo a quicker Grower than the Generality of other Coppice Trees; inſomuch that if it be brought into the Plantation long after the others, it will riſe to an equal Bigneſs with them by the Time of felling; for the common Growth of a Coppice is from twelve to twenty Years the firſt Time; and theſe Aſhes will riſe to very good and uſeful Poles in ſeven Years after the cutting the Shoots down to the Ground.

When the Coppices are rais'd by ſowing, the Aſh Keys may be ſown with the other Seeds, and take their Chance: thus will they only outgrow many of the other Kinds; and there is no great Harm in that; but this Way of introduceing them afterwards, is preferable for many Reaſons. It places them not at Random, that they muſt ſtand when rais'd with the reſt of the Coppice Wood, but juſt in thoſe Places where they will thrive beſt; and the Advantage beforenamed, of thickening the Coppice with ſo uſeful a Growth and in ſo eaſy a Manner, is far from trivial.

There remain two other Occaſions in which the Aſh is beſt propagated immediately from the Seed in the Places where it is to ſtand, that is, in the Woods deſigned for Timber on a poor Ground, and in Parks, and other expoſed Situations. In Woods, when the Soil is good, the Aſh may be brought in at four Years Growth very properly, and will thrive very well, becauſe as much as it is ſtop'd by the laſt Removal, ſo much, or more, it will be aſſiſted by the ſuperior Goodneſs of the Soil. But when that is indifferent; and perhaps worſe than the Ground of the Nurſery, it is beſt to ſow the Seeds there; for no Trees ſucceed well on being tranſplanted, unleſs it is on a better Ground.

As to thoſe Aſhes which are to ſtand ſingly, or in Clumps in Parks, or other expoſed Situations, they are beſt raiſed from the Seed there, for the ſame Reaſon; the Expoſure otherwiſe checking them, if brought from a Place where they were ſheltered, as Nurſeries uſually are, as much as the barren Soil.

In either of theſe Caſes the Method to be obſerved is this. Let the Ground be opened in every Place where an Aſh is intended to be rais'd, to the Depth of two Feet, and very well turn'd, and the Clods broken. When the Ground is thus prepared, let about a Dozen Aſh Keys, of the ſoundeſt and beſt Kind, be ſet in each Place, and defended till they come up by Buſhes laid over, or a low dead Hedge carried round the Spot. When they have ſhot let half of them be pull'd up, leaving the moſt promiſing; and after this, at different Times, let all the others be taken up, except one, leaving the fineſt and moſt regular.

This muſt be carefully done every Time, that the Roots of the remaining Tree may not be diſturb'd. It is then to be defended by Pales, or otherwiſe, and careſully trim'd up in the Winter, to take off all ſtraggling Branches, and carry it up ſtrait and regular. There is no doubt of thus raiſing fair and rich Trees.

The more common Practice for raiſing an Aſh Wood, is to plow the Ground intended for that Purpoſe, and ſow the Keys upon it, thinning them after they are of ſome ſmall Height; or others ſow Oats with the Keys, and gathering that Crop at a proper Seaſon, leave the Keys to ſhoot at their Leiſure, under the Shade and Defence of the Stubble.

We have mentioned this Method of ſowing already, for the raiſing of a Coppice; but for an Aſh Foreſt deſign'd for the Timber, this Method is not comparable to the before-mentioned, which very well pays the additional Labour by the better Growth of the Trees.

At all Adventures, the raiſing ſuch Aſhes as are deſigned for Timber upon the Places where they are to ſtand, is, in theſe Caſes, vaſtly preferable. We deſire Timber Trees ſhould be of an even and uniform Growth; and ſuch they are if rais'd from Seed in their Places, becauſe they meet with no Stop; the Nouriſhment yielded by the Ground, be that more or leſs, being regularly conveyed to them: whereas all Trees have ſome Stop at the Time of tranſplanting, before their Roots have laid hold thoroughly of the new Earth; and none ſo much as the Aſh. It is allowed by all who are concern'd in theſe Tranſplantations, that the Aſh, for the firſt Year after its ſecond Removal, makes very little Progreſs in its Growth; which ſhews the Diſadvantage that ariſes from the Removal; and how much better it is that the Trees of this Kind, deſign'd for Timber, ſhould be ſown in the Places where they are to remain, that they may have no Check in their Growth.

CHAP. XXVI.

Of the lopping and felling the Aſh.

WE have conſidered the Aſh as a Coppice Tree, a Pollard, a Hedge Row, and Foreſt Tree, in the raiſing; and it muſt be regarded in all theſe Lights alſo to the End: for it is frequently uſed in all the four Kinds, and a Method not altogether the ſame is to be followed in treating it under theſe ſeveral Forms. In Coppices it is to be cut with the other Wood, when rais'd in Poles by cutting off the Shoot while young; but when it ſtands for Timber among theſe Plantations, Care muſt be taken it does not ſpread out too much into Head, for the Drippings from that Breadth of Top would do a great deal of Harm to the young Growth after every felling.

When the Aſh is cut as a Pollard Care muſt be taken to keep all its Boughs at ſuch a Height, that they be out of the Reach of Cattle; and the Huſbandman muſt conſider the Aſh is a Tree of quicker Growth than moſt others, and cut off the Shrowds accordingly, oftener than he would from moſt other Kinds. In theſe Pollards he is alſo to obſerve carefully the State of the Trunk. It grows hollow ſooner than many other Kinds, and then it loſes its Value, and yields fewer and fewer Branches for lopping every Time, and they grow more ſlowly. I therefore adviſe the Huſbandman to keep up a Stock of theſe, by now and then planting freſh ones for this Purpoſe, and cutting them off at a proper Height. And theſe being thus ready to take the Places of the old Set, let him cut down theſe as ſoon as they begin to be hollow at the Top, anticipating their Decay. Thus he will have the Benefit of their Branches, for which theſe Pollards are principally rais'd, as long as the Tree bears them in Quantity, and with Vigour; by cutting up the Tree when it begins to ſhew the firſt Signs of Decay, he will have the Advantage of ſo much good Timber as the Tree affords; and he will have freſh and vigorous ones ready in the Places of thoſe he deſtroys. Theſe young Trees ſhould be planted evenly, one between every two of the old ones; and the Roots of the old ones ſhould be grub'd up, that the young may have full Liberty for ſpreading theirs: and thus it will be proper to go on from Generation to Generation, always preparing a Supply in Time.

When the Aſh grows in Hedges it muſt be lop'd carefully, and often: neither the Loppings here, nor in the Pollard Aſh, ſhould be ſuffer'd to grow too large; and the beſt Seaſon for cuting off both is in Spring. It muſt be prevented from having too large an Head in Hedges, as in Coppices, and for the ſame Reaſon to prevent the Miſchief ariſing from its Drippings, and it will thus riſe into a noble and regular Tree.

In Woods and Parks proper Care muſt be taken in forming and training the Aſh at firſt, but afterwards it requires no lopping. It muſt be carried up in a ſtrait and uniform Trunk in Woods: but in Foreſts it may be ſuffer'd to branch out after a certain Height, as from twenty Foot or thereabouts. This takes off ſomething from the Value of the Timber, becauſe of breaking in upon the Length; but it gives the Tree a finer Top, and a more beautiful Aſpect, which is a Thing regarded in thoſe Plantations; and the Quantity of the Timber is not leſſened, though the Value is in ſome Degree abated, for theſe large Arms yield a great deal.

The Time of felling the Aſh is the Depth of Winter, when the Sap is altogether at reſt; for when cut down at any other Time, it becomes ſubject to Worm-eating, and loſes a great Part of its Value. It is to be fell'd in November, December, and January; but beſt of all about Christmas Time. And in felling the Workmen muſt take Care to cut it off as cloſe to the Ground as poſſible; and if it be one that has grown in a Park, or elſewhere, when the Head has been indulg'd, the larger Boughs muſt be carefully cut off while it is ſtanding, or a great deal of the Timber will be ſpoil'd in the Fall. The beſt Time of all for cutting ſmall Aſh, in whatever Form, is toward the Middle of February.

CHAP. XXVII.

Of the Uſes of the Aſh, and its Value in Plantations.

THE Growth of the Aſh, which is quick and regular, recommends it in Plantations about Houſes and Gardens; keeping a due Diſtance between theſe Trees and the Garden Ground; and the Make of its Leaves ſo different from that of the other common Kinds in theſe Plantations, gives a great and a very pleaſing Variety. Thoſe who are curious in Trees ſhould always raiſe Aſh alſo in their Nurſeries for another Uſe, that is, to bud upon it the ſeveral foreign Kinds mentioned in the firſt Chapter on this Subject, all thoſe ſucceeding better here upon that Stock, than when rais'd without budding.

No Wood is ſo ſweet in the Bud as the Aſh, and for that Reaſon there is none on which Cat-

now, though the Beech is liable to neither of theſe Objections as to tranſplanting, becauſe it will very well bear a Removal while young; and will out-grow a Defect in Shape better than any other Tree, yet there is another very ſubſtantial Reaſon for raiſing it where it is to ſtand; which is the Poorneſs of its Soil. It is a general Rule that Trees muſt be rais'd on a poorer Ground in the Nurſery, than that where they are deſign'd to grow; but the proper Soil for the Beech is ſo poor, that the Nurſery cannot well be made in a poorer: and it is certain, that a Tree never does well on tranſplanting, unleſs it be removed into a better Soil.

For the Sake of thoſe who will follow their own Method in all Things, we ſhall, however, lay down the beſt Way of managing it in this Manner.

For the Nurſery Way, let a ſmall Bed be dug in a poor, raw, gravelly or ſtony Soil, and ſome good Beech maſt be gather'd from a thriving Tree, and ſown in it in Trenches three Inches deep, drawing the Earth over it with a Rake. When the Bed is thus prepared and ſowed, it is to be kept clear from Weeds; and when the Plants riſe, they are to be watch'd, and in the firſt Autumn after their ſhooting, ſome of them, where they grow thickeſt, are to be removed into a larger Piece of the ſame Ground: the next Autumn, a ſecond Parcel are to be drawn out of the Seed Bed; and a third Parcel, the Autumn afterwards; then leaving only a few at proper Diſtances, as the others are placed in the new Ground.

Upon the Removal they are to be ſet in Rows a Foot and half diſtant one from another, and the Rows a Yard diſtant; and they are to be kept there three or four Years, digging between the Rows in Spring, and keeping clear of Weeds.

This is the Method where a Nurſery is uſed; but I think the ſowing upon the Spot preferable; and in this ſome Difference is to be obſerv'd according to the Nature of the Plantation. If a large Tract of Ground is intended to be cover'd with a Beech Foreſt, the Plow is to be uſed; but if ſome Clumps of them are to be raiſed in Barks, or other Plantations, the Spade is preferable.

When theſe large Plantations are intended, or where the Trees are to be raiſed for Beauty, a particular Care is to be taken in the Choice of the Seed. The maſt is to be gather'd from the talleſt and moſt beautiful Trees, and to be ſown as ſoon as it has been a little dry'd, by ſpreading on the Floor of an airy Garret, not expoſed to the Sun.

For the ſowing a Foreſt, let the Ground be twice plow'd, and well harrow'd to break the Lumps; and let the Seeds be carefully ſcattered, and well covered. After this when they riſe, let the Weeds be kept under, and from time to time let the Growth be thinned till the young Trees are left ſtanding only at nine Foot Diſtance every Way.

After this let the Planter go through them every Winter, and carefully trim them up for Timber Trees, taking off ſuch ſide Branches as would draw the Nouriſhment from the Trunk; and when he has thus ſet Nature into a right Courſe, let him leave her to herſelf for the Succeſs.

In Parks, and other Plantations, where Beauty is conſider'd as well as Uſe, the Spade is to be employ'd inſtead of the Plow, becauſe the Ground is to be open'd for the Seeds only in a few Places, and the Seeds muſt be more carefully ſet and cover'd.

For this Purpoſe the Beech ſhould be allowed five and thirty Foot Diſtance every Way between Tree and Tree. It will in the Growth very well fill up this Space, ſpreading into a noble Tree, and making an elegant Appearance when full of Leaves, as they are very numerous and ſhining.

At every thirty five Foot let a Hole be open'd, and the Earth being well ſtirred, let five or ſix Seeds be ſet in it at three Inches depth, and at equal Diſtance from one another.

Beech Seeds are very apt to be eaten by Vermin, and the Hope of a whole Plantation may be ſo deſtroy'd, but if they are carefully cover'd at this Depth, they are ſecure.

When they ſhoot up, the weakeſt are one after another to be drawn, and at laſt one Plant only is to be left in each Hole; which is to be defended, as has been already directed for the Oak, and will not fail to grow up into a noble Tree.

It very ſeldom happens that any of ſuch a Plantation die; but to provide a ſupply for ſuch a poſſible Accident, let ſome of the beſt of the young Shoots that are drawn, be ſet out in a Nurſery Bed, where being of an equal Age, they will be ready to ſupply a Failure in the Plantation.

Theſe Beeches are to be trim'd up as they grow, but at five and twenty Foot they ſhould be ſuffer'd to ſend out two or three large Branches, for this makes the Beauty of a Tree for a Park.

At this Diſtance they will not in the leaſt interfere with one another, and if the Soil and Situation favour them, they will grow to a ſurprizing Height and Bigneſs.

In many Places the Beech may be planted in Hedges very profitably; and, as to the Difference of the two Kinds, the Mountain Beech, and the wild Beech, the Planter will be able to raiſe both out of the ſame Parcel of Seed, only by ſowing them in a different Soil and Situation. Thoſe which he raiſes on dry hilly Places, will be Mountain Beech; and the Timber will be white and even grain'd. Thoſe which he raiſes in lower Grounds, and Hedge Rows, will be wild Beeches; and the Timber will be darker in Colour, and though of a more uneven Grain, it will be of a firmer Subſtance, and more durable.

As to the Lopping of this Tree, it requires leſs than moſt others, for the greateſt Care is in the pruning it while young. When this is carefully done, and the Tree train'd to a proper Growth, it produces few ſide Shoots when in Woods; and in Parks it only ſpreads at the Head, as deſign'd. When planted in Hedges, it is to be treated as the Aſh, and other Hedge Row Trees; and when cut for a Pollard, which it may very well be, it is to be ſhrowded once in about eight

Years, and that always in Spring. For if the Shrowding be ſuffer'd to grow too large, or be cut off in Winter; the Wet will get in and damage the Trunk, which is very apt in this Tree to grow hollow from ſuch Injuries.

It is to be felled any Time from the Beginning of the Month of NOVEMBER, to the End of FEBRUARY, but the Timber keeps beſt when it is cut in the Depth of Winter.

CHAP. XXX.

Of the Uſes and Value of the Beech.

THE Beech, when we conſider at large its Uſes and Value, is not to be look'd upon only as a Foreſt Tree, but as one for the Garden. Its Beauty in Parks we have mention'd already, in which Reſpect no Tree whatſoever exceeds it.

In Gardening few Kinds are ſo proper for the making large Hedges to ſurround conſiderable Plantations, or large Wilderneſs Quarters. In this Condition they may, with due Care, be kept very regular, and will be as beautiful as they are uſeful: but the Gardener is to know that this is a very quick ſhooting Tree, and that its young Branches ſoon get Strength: for this Reaſon he muſt be ſure to cut his Beech Hedges twice a Year; for when they are let alone but a little while, he will find it extreamly difficult to get them again into Order.

There is another Reaſon alſo why the Gardener ſhould raiſe a Stock of Beech Plants in his Nurſery. They are very uſeful for receiving the ſtrip'd Beech of both Kinds, by budding or grafting; and it is found to thrive better upon the wild Beech Stock, than when raiſed on its own. This indeed is true of moſt of the ſtrip'd Trees.

We have not recommended the Beech Tree in Coppices, becauſe if ſuffer'd to ſtand for Timber, the Drippings of the Leaves will greatly prejudice the young Growths after felling the Coppice: and for the ſame Reaſon thoſe who ſhall have a proper Soil for raiſing it in Hedge Rows, though they may do this to a conſiderable Profit, yet muſt take Care to lop it in ſuch a Manner, as to prevent the Damage it may otherwiſe do by its Shade, and the Drippings from its Leaves.

It is on the Sides of Hills that the Beech flouriſhes beſt, and yields the fineſt Timber: it will here ſtand againſt the ſtrongeſt Winds, better than almoſt any other Tree, altho' the Ground ſeem ever ſo looſe; but this is owing to its deep rooting, and to the Roots ſpreading ſo greatly at that Depth.

Let not any one be diſheartened if he ſee his Beech Plantation grow ſlowly, for in moiſt Soils 'tis the Nature of the Tree to do ſo at firſt. When it has been thus for two, three, or four Years ſpreading in Root rather than Top, it will begin of itſelf to thrive, and will go on without Stop or Interruption till it be arrived at its full Maturity, in which it exceeds moſt other Trees in Size.

The Fruit of this Tree called the Beech Maſt, is a moſt excellent Food for Hogs, and many other Creatures. Deer are very fond of it; as alſo Pheaſants, and many Kinds of Poultry. It fattens theſe Creatures excellently, and their Fleſh is never better taſted. The Leaves of the Beech are light and dry, when properly cured, beyond all others. It has been a Practice to ſtuff Mattraſſes with them. There is alſo another Uſe to which the Fruit of the Beech may be put, that is, the preſſing it for Oil; this it yields in ſuch Quantity, that a Buſhel affords a Gallon, and it is ſo ſweet and well flavour'd, when drawn with proper Care, that it may be eaten as Oil of Olives; and will ſerve excellently for ſeveral Purpoſes for which Oil of a large Price is uſed.

There was ſome Years ago an Undertaking ſet on Foot for the making this Oil, but it was ill contrived and very injudiciouſly executed, ſo that 'tis no wonder it fail'd: but that is no Argument againſt the ſetting about it again upon better Principles, and with wiſer Management. There is no Doubt to be made of its Succeſs for the Quantity and Quality of the Oil enſures it.

Thoſe who ſhould entertain Thoughts of ſuch an Undertaking, are not to be diſcouraged at the ſmall Quantity of Maſt they will ſome Years ſee on the Trees. The Beech does not bear regularly; but in general about one Year in three is a good one; and the Produce then is prodigious.

Thoſe who are curious in obſerving the Growth and Succeſs of Fruits, have often expreſs'd their Surprize at the great Difference there is found in the Quantity on the ſame Tree in different Years; and the more ſo as after keeping a ſtrict Watch of the Seaſon in that whole Year, they have frequently found nothing particular to occaſion it.

Several ingenious Perſons have mention'd this to me, and I ſhall take this Opportunity of propoſing my Opinions concerning the Cauſe, as there is no Kind ſo much liable to this Uncertainty of bearing as the Beech. The ſame Tree in my Neighbourhood having to my Knowledge yielded ſome Years not above ſix or eight Buſhels of Maſt, and ſome others fifty.

They who enquire ſo far into the Cauſe of this, as to examine the Seaſons of that Year, ſhould go a little farther back, and take Notice of thoſe in the preceeding. It is certain that the Weather of one Year will ſhew its Effects in the Fruits of another, eſpecially in Trees that grow on looſe and open Soils, and this in the common Courſe of Things is in no reſpect more the Caſe than in the Beech.

When one Year has been remarkably wet, it has been found to affect the Fruit of that which follows, and particularly ſuch as is produced by Trees that grow on looſe and open Ground: I ſhall mention, by way of Inſtance, the Vine. When one Year has been very wet, if the Vines be examin'd the next, they will be found to ſuffer by it extreamly; for, notwithſtanding there be ever ſo fair a Promiſe in the Spring, and the blooming Seaſon go on ever ſo well, very few Bunches of thoſe which ſucceed,

will come to any Thing. Nay, the Gardeners, without ſeeing the Cauſe ſo far back, will, at the pruning Seaſon, be able to foretel a bad Year at theſe Times, the bearing Shoots being poor and crude. On ſuch Occaſions the firſt Crop fails, and often a ſecond is produced, but this is always too late in the Year for its arriving at any Perfection.

On the other hand, whenever there is a remarkably dry Autumn, the next Year there is Plenty of fine Grapes, let the Seaſon of that Year be what it will: and as this is plainly the Caſe in theſe Shrubs, it doubly holds in reſpect of other Trees which grow in looſe Soils, and bear irregularly. I am perſuaded from what I have ſeen of the Beech, that its bearing Years are influenced by the preceeding Seaſon, and may be foreknown accordingly; but what I have collected from my Obſervations on this Head, is not yet enough to form a Syſtem.

After the Uſes of the Fruit, let us enquire into thoſe of the Wood of the Beech. In its ſmaller State, the Branches, as well as the worſt Pieces of the Timber cleft, make a bright, clear, and pleaſant Fire. The ſmall Wood makes excellent Charcoal, and the Aſhes are prefer'd to many other Kinds for uſing in the making of Glaſs. Turners uſe a great deal of the well grain'd Beech in Inſtruments, for it cuts eaſy, and is capable of a good poliſh.

The large Timber is uſed in many Kinds of Work. It will ſtand excellently in Water, where it is always wet, but it will not do where it is wet and dry at Times. The Evenneſs of its Grain, and its not being liable to ſplit, recommend it greatly to the Joiners and Cabinet Makers. Our Bedſteads in general are made of Beech; and it is the common Groundwork of thoſe Pieces of Furniture which are inlaid with Mahogany, Roſewood, or other expenſive Kinds.

It makes good Buckets, Trays, and other Utenſils, as Trenchers, and the like, being eaſily kept clean, and looking very pretty when ſo: and not being ſo liable to crack as many other Woods.

There is another Uſe which makes a large Demand for good Beech, which is the ſpliting it into thoſe thin Boards of which Ban-boxes, Hat-boxes, and ſuch other light Things are made. Theſe are all in general made of the Beech, becauſe no Wood ſplits ſo fine, or holds ſo well together. The ſplitting it for this Uſe is a very pretty Operation, it was invented abroad, and when the Knowledge of it got into ENGLAND, was for ſome time kept a great Secret.

The ſhavings of Beech are bought up by the Wine Coopers, being uſeful in the fining of Wines, and they are a very innocent Ingredient; which cannot be ſaid of all that are uſed in LONDON for that Purpoſe.

The beſt and fineſt Beech in ENGLAND grows in HAMPSHIRE, from whence great Quantities are ſent up annually to LONDON; it there is planted generally on a dry ſtony Soil, and in high Situations.

The Beech would be a very proper, and a very beautiful Tree for long Walks and Avenues, where the Soil and Situation are proper, for no Tree makes a more beautiful Appearance, or affords a finer or more wholeſome Shade, it is therefore a Wonder 'tis not more cultivated in general throughout the Kingdom.

CHAP. XXXI.

Of the white Poplar, its Soil and Situation.

WE have in ENGLAND four diſtinct Kinds of Poplar, though ſome of them are called by other Names. In this Chapter we ſhall treat of two of thoſe four, which are nearly of kin to one another, and are too often confounded together. Theſe are the white Poplar, and that Kind called the Abele, for theſe may very fitly be conſider'd as two white Poplars; the other two Kinds are the black Poplar, and the aſpen Tree, which differ conſiderably from theſe, and from one another.

The white Poplar is a large and beautiful Tree, of an upright and ſtately Growth. The Leaves are ſhort, broad, and pointed at the Ends. The Flowers grow on ſome Trees, and the Fruits on others, whence the Poplars of all the Species are properly enough diſtinguiſh'd into Male and Female Trees. Theſe Flowers, which grow on thoſe called Male Trees, are compoſed of ſeveral little Leaves, and a great Quantity of ſhort Threads; and the Fruit which grows upon the others called Female Trees, is a Sort of Pod of a thin membranaceous Subſtance, which, when ripe, ſeparates into two Parts, containing the Seeds of the Tree lodged among a Quantity of ſoft downy Matter of the Nature of Cotton.

Theſe Characters agree equally with the two Species of white Poplar. The Difference between them is, that the Kind commonly called the white Poplar, has ſmall Leaves, and a rough Bark toward the Bottom of the Trunk; whereas the other called the Abele, has larger Leaves, and the Bark is ſmooth uſually all the Way up.

Theſe two Kinds are nearly equal in Value, and therefore it is beſt to plant the Abele, becauſe it ſomewhat excels the common white Poplar in Beauty.

The proper Soil for the Abele is a moiſt rich Ground, and it ſucceeds beſt in a flat and low Situation. They are excellent where there is Plenty of Moiſture; and will grow to great Advantage in many ſuch Places, where no other Trees can thrive; and, in ſome, where nothing elſe will grow.

It is not a great while that we have got into a Way of planting this Tree in ENGLAND; we learnt it from FLANDERS, where Nurſeries of Poplar are as common as of Elms with us; and 'tis to be hoped a Practice ſo profitable will become univerſal for many an Eſtate may be prodigiouſly improved by planting boggy Places with this Tree.

The Willow is at preſent almoſt the only Fen Tree. But the Poplar will thrive in moſt Places when that ſucceeds, and is a much more profitable Growth to the Owner.

Nothing is more wanted in ENGLAND than a general

general Knowledge of the Nature of Timber Trees, which would at once encourage the Taſte for planting, and make it ſucceſsful. Few turn their Thoughts to it; and of thoſe who do ſo, the moſt ſeem not to know that there are above three or four Timber Trees in the Kingdom. Their Thoughts are all directed to the Oak, Aſh, and Elm, or ſometimes, but very rarely, they take in the Beech; and if one or other of theſe will not do, the Ground is declared not fit for planting.

Not one of theſe four will grow on the rotten Soil of a Fen, but the Abele will flouriſh there, and will yield the Owners a vaſt Profit; and this on Grounds which he has never made any Uſe of at all.

There is a farther Conſideration which ſhould induce them to planting it, which is, the Quickneſs of the Growth of this Tree, in which it exceeds almoſt all others.

A great Objection to planting is the Length of Time requir'd to reap its Benefits; People are unwilling to labour for Poſterity: but in Plantations of the Abele they will work for themſelves, a very few Years raiſes vaſt Trees of this Kind, and there is a ready Market.

A Man muſt not look for the full Advantage from an Oak Plantation in his own Life, and for that of an Aſh or other quick-growing Tree, as they are called, he muſt wait forty Years; but when the Abele is the Tree, eight or ten Years raiſe it to a very profitable Bigneſs, and it arrives at its full Growth in leſs than twenty on a proper Soil, and ought to be then fell'd, and a young Plantation prepared to ſucceed the old one.

Not only the Profit ariſing from ſuch a Plantation, but the Beauty and Ornament it affords, which are very great, ſpeak for its being fell'd at a proper Time, which in general is about the Age I have named: for after this the Trees grow knotty and unhandſome; and every Year decreaſe in the Value of the Timber, which conſiſts greatly in the Evenneſs of the Grain.

The Abele makes a very beautiful Avenue to an Houſe in a proper Situation; and even the Trees, in this Caſe, ſhould be fell'd at their full Growth, others having been planted between to ſucceed them. Their Roots ſhould alſo be ſtub'd up, to favour the Growth of the new Plantation; and in this eaſy working Ground their Value, as Fuel, will pay the Expence of taking them up. An Avenue of them may be thus kept up from Generation to Generation, and always in Vigour, whereas, otherwiſe, they would ſoon grow deformed.

But though the Abele, or white Poplar, is very proper for an Avenue, it muſt not be planted near a Garden, becauſe, in that Caſe, it would have all the Inconveniences of the Elm and Aſh together, and more of its own. Its Roots would ſpread over the Garden Ground like the Aſh, and rob every thing of Nouriſhment: they would ſend up Suckers every where like the Elm, and ſpoil both Graſs and Gravel; and beſide this the downy Matter about their Seeds will cover the Place with a Litter that is very difficultly removed, for many Months together.

CHAP. XXXII.

Of the Propagation and Uſes of the white Poplar.

THESE Trees may be rais'd from Seed, if any one ſhould fancy ſuch an Undertaking, but it is altogether needleſs, as they are to be had ſo many other Ways, with ſo much leſs Trouble.

They are to be propagated either by Layers or Cuttings of any Kind; or by Suckers drawn up from about the old Trees; or by Stakes, which being planted in a right Soil, will take Root as freely as a Willow Stick, and grow to a vaſt Bigneſs in a ſhort Time.

Of theſe ſeveral Ways I would adviſe that by Layers, which will always afford the evenneſt and moſt beautiful Trees; and theſe take Root ſo eaſily, and bear tranſplanting ſo well, that it is pity to uſe any other Method in general. However, when a Man intends to raiſe only a few, he may be content with Suckers; and when he is in great Haſte to have a good Shade, he may uſe the other Method by Stakes, for they ſhoot up quickeſt of all, though they make the leaſt beautiful Trees.

When Suckers are uſed they are beſt taken up in the Middle of OCTOBER, and being then planted in the Places where they are to ſtand, they will quickly arrive at a good Heighth.

But if this be not quick enough, and the Method of Stakes be prefer'd, let them be cut at about ſix Foot Length, and of the Thickneſs of a Child's Wriſt. Theſe are to be ſtruck off by one ſloping Blow at the Bottom, and thruſt fifteen Inches deep into the Ground, and no farther Care need be taken of them.

But to raiſe the Abele regularly, the Way is by Layers. To this Purpoſe the Stools muſt be planted in a rich and moiſt Ground, and treated exactly in the ſame Way as the Elm Stools for Layers, deſcribed under that Head. Theſe will yield a continual Supply of beautiful and well growing Plants, which being removed carefully into the Place where they are to remain, will, in half a dozen Years, be thirty Foot high, and as thick as a Child's Waiſt; they will ſometimes ſhoot nine Foot in a Seaſon.

The Quickneſs of Growth, and great Beauty of this Tree, are ſufficient Recommendations to thoſe who want quick Pleaſure or quick Profit. And the Uſes of the Wood are many. Indeed they are not ſufficiently known, nor is its Value.

In the firſt Place, no Wood whatſoever requires ſo little ſeaſoning, for none ſhrinks ſo little: nor is any Wood whatever leſs affected by the Weather. All Kinds of Timber will ſwell and ſhrink with the different Heat and Cold, and Moiſture and Dryneſs of the Air, but none ſo little as the Wood of the Abele, or broad-leav'd white Poplar; for this Reaſon it is very fit for many Uſes about Houſes, to which alſo the Whiteneſs of the Timber, and beautiful Grain greatly recommend it, though it be deficient in Hardneſs. What could be prettier than to ſee the Floors and Wainſcot of a neat Country Houſe of this Wood, which would have the great Advan-

tage

tage never to ſhrink or ſwell, and would be kept clean and beautiful without Paint.

But not to dwell upon the Uſes to which it might be put, let us mention thoſe to which it is. The Wood of the Abele is excellent for Turnery Ware, nothing works more eaſily and freely, nor does any thing anſwer better for the ſeveral Kinds of Diſhes, Bowls, and other wooden Veſſels. A large Quantity of it is uſed by the Bellows-makers; and it is the Wood of which Shoe-heels are commonly made, which it is extremely fitted for, becauſe it is light and tough.

Its Lightneſs makes it alſo ſupply the Place of Cork, on many Occaſions, as for the floating of Nets, and the like Purpoſes. And where a great deal of Strength is not required, it has the Advantage of many other Kinds of Timber for making Carts and other Country Carriages, becauſe of its Lightneſs.

The Loppings are tolerable Fire Wood, and the Poles that grow up ſtrait and regular ſerve for the Hop Planters and Gardiners, on a great Variety of Occaſions.

Where Birch is ſcarce they ſometimes make Brooms of white Poplar Twigs, but for this Service the black Poplar, or Aſpen Twigs, are more proper, becauſe longer and tougher.

CHAP. XXXIII.

Of the black Poplar.

THE black Poplar is altogether like the white in its Flowers and Fruit, which grow on different Trees of the ſame Species: but the Quantity of white downy Matter in the Fruit of the black Poplar, is more than in any other Kind, from whence ignorant People have call'd it the Cotton Tree. The Leaves are ſmaller and rounder than thoſe of the Abele, and they are of a dark ſhining Colour, and its Twigs are of a deeper Hue, and longer, ſlenderer, and of a tougher Subſtance.

The black Poplar loves a rich and moiſt Soil, as well as the white, but it will bear a little dryer Ground; and will thrive on more expoſed Situations. For this Reaſon the Planter ſhould make his Choice of the Kind, when he intends to raiſe Poplar Trees, according to the exact Situation and Condition of the Ground. Where that is low, rich, and moſt, it is indifferent which he chuſes; but where it is either altogether, or in any Part, a little higher, or a little leſs damp, he muſt prefer the black. The Trees are ſo much alike in their Growth and Appearance, that they may be planted together, with this little Diſtinction, of giving the loweſt Places to the white, and the higher to the black; and it will never be regarded in the Regularity or Appearance.

From what I have ſeen, the white Poplar, or Abele, in general, will do beſt on the Fens, and the black Poplar on thoſe Bogs which lie between or upon Hills; for this bears the Expoſure better. But then, as theſe Bogs are often wetter than the Fens, this is a Caution to be obſerved, that the black Poplars ſhould be planted about the Skirts and Edges of the Bog, and then the white and Abele may be planted in the Middle, where there is Firmneſs enough to ſupport them, for they will thrive very well there, under the Shelter of the others.

In many Places the Bogs between Hills are too wet and ſoft to ſupport the Roots of any Tree, if not qualified firſt by a little draining, which may uſually be done at a very ſlight Expence.

The black Poplar may be propagated by any of the Ways laid down for the raiſing of the white; but the Method by Layers is preferable to any other: and indeed in this Kind it is ſo far the more proper, as this will not always take Root ſo freely as the white.

The Method of planting the white by Stakes does very well, but it will not do for the black, at leaſt not conſtantly, for they frequently miſcarry.

But for thoſe who will not be at the Trouble of a Nurſery for the raiſing Layers, the Suckers may be taken up from about the Roots of the old Trees; and in want of theſe, very good Trees may be rais'd by planting ſmall Cuttings, only theſe require a little more Care, and ſhould be ſhaded at firſt. Theſe Cuttings ſhould be eighteen Inches long, and planted a Foot deep in the Ground; and thus they riſe to fine regular Trees.

The Timber of the black Poplar is very like that of the white, but ſomewhat firmer. The Turners prefer that of the Abele to all the other Kinds, which they diſtinguiſh by its whiter Colour, and more even Grain; the common white Poplar they eſteem next to that, and the black laſt: but the Difference is not great; and for Things of any Size, or where ſome Degree of Strength is required, the black is to be prefer'd to either of the others. They make Wheelbarrows and light Carriages of it in FLANDERS, where it is more common, and they laſt very well, and none are ſo light except of the other Kinds of Poplar which have not ſufficient Strength, unleſs worked up in a particular Manner, and with a much larger Quantity of Timber, ſo that they loſe one Way what they get another.

The Wood of both the black and white Poplar are uſed by the Carvers, but they prefer the black for the niceſt Works.

CHAP. XXXIV.

Of the Aſpen Tree.

THE Aſpen Tree is a kind of Poplar, and is call'd by thoſe Authors who write on Trees, the Poplar with trembling Leaves. It reſembles the Poplars in the Flowers and the Fruit; but its Leaves are rounder, and they ſtand on long, weak, and ſlender Foot Stalks. This is the Reaſon of their trembling Motion which they have, in a great Degree, with every Wind, and which makes them agreeable in the View of Buildings. There is ſomething ſo pretty in this Tree, upon the whole, that one is ſurpriſed it is not rais'd more frequently for Ornament. But 'tis left to the Woods, and rarely ſeen elſewhere.

The

The leaſt Wind ſets the Aſpen Leaves in Motion, and as they grow very thick upon the Tree, they rattle gently againſt one another, and the Noiſe is ſo like that of a diſtant Waterfall, that it would be taken for nothing elſe by any body who had not been accuſtomed to ſee what it was.

If we add to this its quick Growth, in which it reſembles the other Poplars, though it does not quite equal them; its regular Appearance, when kept in tolerable Order, and the Value of its Timber, one would think it ſhould be enough to recommend it to the Curious in theſe Matters, and that it may no longer be left a neglected Tree.

The natural Soil of the Aſpen Tree is a rich and moiſt Earth, and it thrives beſt in flat and level Places; but tho' one of the watery Trees it is not ſo ſtrictly as ſome others confined to that Situation, or Soil, for it will ſucceed tolerably on higher Grounds, and where there does not appear any particular Dampneſs. I have obſerv'd, however, that when it thrives in theſe Places, there uſually is a Clay at Bottom. I have mark'd its favourite Soil in high Grounds, and found that to be almoſt univerſally a rich loamy Earth, with a clayey Bottom.

In ſuch Places the Huſbandman may plant the Aſpen with a fair Proſpect of Advantage; and in low Places that are not too wet, he will never be diſappointed of its thriving quickly. It attains its Growth ſooner in theſe low Situations, but the Timber is better when it has grown on higher Grounds. But this Tree is never to be raiſed on Gravel, Sand or Chalk, for it will make no Progreſs, nor will the Wood be good.

The Aſpen is beſt propagated by Layers, which take Root very readily, and a ſufficient Supply whereof may be had from a few Stools, as directed under the Article Elm. But for ſuch as want only a few Trees, 'tis not worth while to wait this Time, and they may therefore raiſe them from Suckers, which riſe every where in Plenty about the old Trees.

Theſe ſhould be taken up in the Middle of February, and planted immediately.

They will ſtand very well in Rows, Avenues, or Clumps; and may be planted in proper Soils in Hedge Rows; for their dripping is not ſo hurtful as that of many other Trees. They alſo are a very good Addition to Coppice Woods; but whether in thoſe or whatever other Places they are planted, they ſhould be trim'd up for Trees, not cut for ſmall Wood, or lop'd for Pollards; for they do not yield a good Fire Wood, the young Shoots being too ſpungy.

This is a Fault alſo of the black Poplar, and of the common white Poplar; the Abele is the beſt of all the Claſs for Fire Wood, and that but indifferent.

When the Aſpen is firſt planted, the Side Shoots muſt for this Reaſon be trim'd off, and the Tree rais'd with a naked Trunk; its Timber Part will then grow apace, and the Head will be large and beautiful.

The Aſpen is not quite ſo ſpeedy in its Growth as the other Poplars, but it riſes ſufficiently quick into a fine Tree. From five and twenty to two or three and thirty Years may be allowed, according to the Differences of the Soil, for the Time of its growing to a full Maturity.

It is to be felled in the End of November; and the Timber is fit for many Uſes. It is called for in ſome Places by the Builder, and anſwers very well in Beams and Boards: in general where it is moſt known, it is the moſt valued, for there are many of our Counties where it is only ſeen here and there a Tree; and gazed at for a Rarity, becauſe of the Motion of its Leaves with the Wind.

Chair Frames and Tables are made of it in many Places; and in ſome it is ſplit into Pales for Parks, and Laths for Malt Kilns; for all which Purpoſes it is very fit. The Turners alſo uſe it for Bowls and Diſhes. In ſome Places Trenchers are turn'd of it, but it is not ſo fit for this Uſe as many other Woods: it is white and light, but the Grain is too looſe.

In ſome Counties they cut it off for ſmall Wood, among the other Coppice Kinds, but it is where they don't underſtand its Management. Its principal Uſes, when of this Size, are for Hoops, for Fuel, and for burning into Charcoal, but it does not anſwer well to any of them; for the Hoops are too brittle; and, as to firing, it ſmothers and ſmoaks, and the Charcoal made of it is but poor.

We name this ſo freely, that the Huſbandman may not be miſled by ſuch Writers, as copying one another inſtead of conſulting Experience, ſet down theſe for the Uſes of the Aſpen Wood. A Man who ſhould find it unfit for theſe, and take it upon truſt from them that it would do for no others, might give up the Intent of planting it, but tho' it is not ſerviceable for theſe Purpoſes, Experience ſhews it is for others.

CHAP. XXXV.

Of the Sycamore.

THE Tree which we commonly call the Sycamore, is of the maple Kind, and has been much more properly named the great Maple, but in general it is not known by any other Name than Sycamore.

It is a large ſtately and fair growing Tree. The Bark is tolerably ſmooth, and of a duſky brown. The Wood is ſoft and whitiſh; the Leaves are very large and beautiful, they are broad and divided in a pretty Manner at the Edges, the Flowers are thready and inconſiderable; the Fruit is like the Aſhen Key, but larger, and makes a pretty Appearance. Upon the whole, few Trees are better calculated for ornamental planting; ſo that 'tis ſtrange it is not more generally uſed.

The natural Soil of the Sycamore is a rich but light Mould, where there is ſome Degree of Moiſture, but it is not confined ſtrictly to ſuch: It will grow on almoſt any Land. We have in many Parts of England, Inſtances of its ſucceeding on gravelly and ſtony Grounds; but beſt when there is Water near.

The beſt Situation for the Sycamore is a Flat, becauſe it loves Water; but it will grow on Hills, and it has one particular Advantage, that it will bear to be planted near the Sea, where ſcarce any other Tree will grow. It bears the Spray very well itſelf, and by its Breadth of Leaf, excellently defends any other Trees from it in the Summer; and 'tis of ſo quick Growth, that its Body and Arms ſoon become qualified to do the ſame Service in Winter.

This is a Thing worthy the Planters very particular Notice, becauſe he has by this Means not only a Tree that will ſucceed, where otherwiſe he could make no Plantation; but it will defend a Plantation of any other Kind under the ſame Diſadvantage.

The Sycamore may be raiſed either from Seed, or by Layers, or Suckers. The firſt is greatly the beſt Method, and this ſucceeds moſt happily of all, when the Trees are ſown on the very Spot where they are to ſtand: but it does very well either of the other Ways; the Layers are produced from the Stools in great Abundance, and root eaſily; and the Suckers alſo grow readily: but the Trees raiſed from the laſt are uſually inferior to the others in Beauty.

The Seeds are produced every Year in great Abundance. They ripen about OCTOBER, and are to be ſown immediately after in good Earth. If they are raiſed for Removal, they ſhould be ſown in Trenches three Inches deep, drawn at ſmall Diſtances; if on the Places where they are to ſtand, half a dozen Keys are to be laid in a Hole dug for that Purpoſe, and cover'd three Inches deep with Mould. They ſhoot up the next Spring, and grow very quickly.

If they are thus ſown in a Nurſery, they muſt be removed the next OCTOBER into another Part, and planted at a Foot Diſtance, in Rows two Foot and a half aſunder: after two Years Growth in theſe, they may be planted where they are to ſtand.

Whether it be raiſed from Seeds, or Layers, or Suckers, the Side Branches are to be trim'd off for the three or four Years ſucceeding the laſt Tranſplantation; and after that they may be left to Nature. The ſame Method is to be obſerv'd with thoſe raiſed on the Spots where they are to ſtand. Of the half Dozen that ſpring up in each Hole, only one is to ſtand; the others are to be pulled up one by one at different Times, and the fineſt left. This is to be trim'd up that it may grow to a Body. And if theſe Holes are dug at five and twenty Foot Diſtance in a double or treble Row, there will in a very few Years be a beautiful Plantation.

The Gardeners keep a Sycamore with Leaves ſtrip'd with yellow, and this has ſomewhat ſingular in it, that the Tree bears its Fruit very regularly, and if its Keys are ſown, they always produced ſtrip'd Trees, which is not the Caſe with the Generality of theſe artificial Beauties, they requiring to be budded or graſted; their own Seed generally raiſing a plain leav'd Kind.

The Sycamore is not one of thoſe Trees that produces a good ſmall Wood, nor indeed do any of the ſoft Kinds, it is for that Reaſon we have adviſed the raiſing it always with a trim'd Trunk for Timber. The ſmall Wood does not burn well: but the Timber has many, and thoſe very conſiderable Uſes.

The beſt Time for felling the Sycamore is in the Beginning of DECEMBER; and 'tis always uſeful to have a freſh Stock of Trees raiſing between the old ones, that may thrive and grow up when they are gone. This is an eaſy Method, and ſhould be practiſed in all quick growing Trees.

The Shade and Shelter of the Sycamore is excellent; and as it will bear the Miſchiefs of the Sea, it will alſo reſiſt the ſtrongeſt Winds, ſo that no Tree is equal to it for the ſheltering other Plantations. In ſome Places we ſee them in Hedge Rows, but rarely, though wherever it is ſeen 'tis counted a great Beauty. The only Part of ENGLAND where it is common, is the Biſhoprick of DURHAM, where they have from Time immemorial been uſed to it, and plant it in Hedges, Walks, and about Houſes in great Abundance.

When the Soil and all Things ſuit, it will grow to a vaſt Size. Trees of five, ſix, or ſeven Foot in Diameter are not uncommon, and at this Bigneſs frequently found throughout. It reaches this Size alſo much quicker than the Generality of Trees: for in the common Courſe of Nature, thoſe Trees whoſe Wood is ſoft, arrive at their Bigneſs ſooner than thoſe the Wood of which is harder.

The Timber is white, and of a beautiful Grain. It is uſed very much by the Turners, they make of it wooden Platters, Bowls and Trenchers, Spoons, Ladles, and other of the ſmall Utenſils of the Kitchen. Some have uſed it in the Inſide-work of Houſes; it is not very ſtrong, but it ſhrinks little.

The Sycamore may be tranſplanted when very large, only that too much Head muſt not in that Caſe be left on; but it ſoon recovers the Loſs by the Axe, growing from an old Trunk, when once rooted, very freely. When the Head or large Branches are lop'd on this or any other Occaſion, the wounded Place muſt be cover'd over with a Cap of Lead, or Oil Cloth; or elſe with a Mixture of Clay and Dung, otherwiſe it very eaſily lets in Wet to the utter Deſtruction of the Tree.

The Sycamore is a Tree Bees are very fond of, and it is of great Uſe to them; for it is oftener cover'd with a Honey Dew than any other Tree whatſoever. For this Reaſon alſo it is frequently over-run with Inſects of many Kinds; for this Honey Dew is their Food, and where the Food is they will be found.

CHAP. XXXVI.

Of the Lime Tree.

THE Lime is a large, and naturally, a well growing Tree. 'Tis often injur'd by cutting into fooliſh Forms, but in its own Growth it is very beautiful. The Bark is brown and tolerably ſmooth, the Wood light and fine: the Leaves are broad and roundiſh, but that they

they end in a point. The Flowers are of a pale whitiſh Colour: each is compos'd of ſeveral Leaves which ſtand hollow. There is a longiſh Leaf on the Stalk of each Bunch of Flowers, and the Fruit is a ſmall double Seed Veſſel of a teſticulated Shape.

There are three Kinds of the Lime Tree cultivated here. 1. That with larger Leaves called the common Lime. 2. The ſmall leav'd Lime; and, 3. That with red Twigs. The Leaves of this laſt Kind are a little hairy, and the Fruit is ſquare. There is alſo a ſtrip'd Lime Tree common in the Nurſeries, but it is no other than the common Lime alter'd by Art; and there are ſome others not worth the Planters Notice.

The beſt Soil for the Lime Tree is a good rich loamy Earth, where there is Depth and Room for the Roots to ſpread. But it will grow in others. Too much Moiſture is an Enemy to it, and ſo is exceſſive Dryneſs. Where the Soil is a cold Clay, apt to detain Water a great while, the Lime ſhould not be planted; for the Wet always chills, and frequently rots the Roots. Where there is a poor Gravel, or a very ſtony Land, it is not fit for the Lime. But in a Gravel with a good Mixture of loamy Earth, ſuch as are the beſt of the gravelly Soils in Buckinghamshire, and elſewhere, it thrives very well.

This Particularity with reſpect to the Soil for the Lime, is the more needful to be obſerved, becauſe its Bulk depends upon it: and it is for this Reaſon that few now grow to a proper Maturity.

In ſandy Soils the Leaves of the Lime come out a Fortnight ſooner than in others; and in wet, clayey and cold Lands, they fall two Months before their Time. This may be a Mark to the Planter, whether the Soil ſuits the Tree. For the too great Forwardneſs of the Leaves is as bad a Token as their too early Decay.

In ſuch Soils the Lime will live without flouriſhing; and thoſe who have ſeen it only in ſuch, will not know what may be its Value. The Lime, in a favourable Soil, will grow to ninety Foot in Height; and has been meaſured twelve, fourteen or ſixteen Yards round the Trunk, and entirely ſound.

'Tis not only here and there a Tree that thrives thus, whole Plantations riſe to ten Yards round with great Regularity; nor is the Lime one of thoſe ſlow growing Trees, that reſerve their Profits for another Generation.

The Huſbandman who knows this, will ſee what may be the Advantage of planting this Kind when he has a proper Soil. For, as the Timber is of ſome conſiderable Value, ſuch a Quantity as is contain'd in Trees of this Height and Bigneſs, is an Article very well worth his Regard.

The Lime loves a Situation ſomewhat raiſed. It will grow very well on Hills; but upon a ſmall Aſcent, with a due Depth of ſome free Soil, is the Place of its greateſt thriving.

It may be propagated three Ways, by Seed, by Suckers, or by Layers; but the laſt Method is much the beſt. If any one chuſe to raiſe it from Seed, he muſt gather his Seed carefully in the End of October, when it is fully ripe, and from a thriving Tree. This he is to lay up in Sand till February, and then ſow it in a Nurſery Bed, from whence the young Trees are to be removed the firſt Autumn into another Part of the Nurſery, and tranſplanted into their proper Places at four or five Years Growth.

Thoſe who want only a few Trees, may raiſe them from Suckers taken from the Roots of the old ones, chuſing the ſtraiteſt and beſt, and ſetting them at once where they are to ſtand; defending them by a Hedge, Pale, or Buſhes, till they have got a little Strength.

But the Way I adviſe is to raiſe them from Layers, as directed under the Article Elm. The Stool muſt be planted in a deep light Soil. The Shoots are to be laid down in September; and the September following they muſt be removed into Beds four Foot diſtant in the Rows, and two Foot from one another. They are to ſtand in theſe Beds four Years, and then to be removed to the Places where they are to ſtand, after which they require little or no farther Care.

While they ſtand in the Nurſery it will be well to dig up the Ground every Spring between the Rows, and to take off all the large Side Shoots, leaving only the ſmall ones to detain the Sap.

There is little Difference in the Timber of the three Kinds of Lime Tree. The ſmall leav'd Sort yields ſomewhat the hardeſt Wood: the other two ſhew ſcarce any Difference. They bear more Moiſture, and a lower Situation, than the ſmall leav'd one; and by this the Planter may be directed in the Choice of his Kind, ſuiting it exactly to the particular Nature of his Ground.

The Lime may be tranſplanted at a very large Size, by taking it up with a Ball of Earth about the Root; but to enſure the Succeſs, the Head ſhould be cut off. In this Caſe leſs Care and Trouble are requir'd in the doing it. The wounded Part in theſe Tranſplantings, muſt be well ſecured by a Covering of Clay and Dung, or in ſome other Manner as has been before directed, and there is then no Fear of Hurt.

The Beauty and free Growth of the Lime have recommended it greatly for Walks and Avenues; and the Fragrance of its Flowers is a great Conſideration in its Favour, but the Leaves decay ſo ſoon that many are diſpleaſed with it. 'Tis one of the firſt Trees that puts us in mind of the Approach of Winter, and in a diſagreeable Soil much ſooner than in others. Its Leaves will ſometimes fall in the End of August, ſo that it is a Month or five Weeks ſooner than the Generality of our other Trees. This diſagreeable Circumſtance, together with the Dirt and Litter ſuch a Number of Leaves make, diſguſts People very much, and has baniſh'd it from many Gardens; but, in a proper Soil, the Planter will not find the Advantage leſs, becauſe it wants ſomething in the Article of Pleaſure. And to anſwer thoſe Diſadvantages that have been named, it has two Benefits in which few Trees excel it: ſcarce any Tree bears the Fury of the Winds better, or is leſs

liable to ordinary Accidents; and it is very little apt to grow hollow.

In many Plantations of ſome ſtanding, one ſees the Elms ſhatter'd by Winds, and decay'd within; while the Limes in the ſame Place, tho' they have grown longer than was needful for Profit, are entire, ſound and flouriſhing, though expoſed to all the ſame Accidents.

The Wood of the Lime is light, and of a good Grain, not liable to ſplit. It cuts eaſily, and is excellent for Carvers. It is the common Wood uſed in making of Models; and the Turners make a great deal of their Ware with it. The Farmer and Huſbandman prefer it to others for many of their Implements, as it is very light, and yet of ſufficient Strength: and 'tis fit for paling, and the other common Uſes of Timber.

The Gun Powder Makers are very fond of the Coal of the Lime Tree, they always uſe that of ſome light Wood, frequently the Alder, ſometimes the Willow, but none anſwers ſo well as the Lime, becauſe a well-burnt Piece of fine Charcoal has the Qualities of the Wood, and is light and ſtrong both.

CHAP. XXXVII.

Of the Walnut Tree.

THE Walnut Tree may be conſider'd by the Gardener on account of its Fruit, but the Value of its Timber gives it a Title to ſtand among our Liſt of Trees raiſed for that Purpoſe, ſince it will be very well worth the Huſbandman's while to plant it, independently of any other Conſideration. The Quantity, as well as the Price of the Timber, is a very great Article in this Account.

It is a large ſpreading and beautiful Tree. The Leaves are each compoſed of ſeveral others ſtanding on the two Sides of a middle Rib, with an odd one at the End. The Bark is of a pale brown, and ſmooth; the Wood firm and beautifully vein'd. The Flowers are little and inconſiderable, they hang in Strings, and are compoſed of ſome Threads and chaffy Leaves: the Fruit in the Walnut, conſiſting of a green ill-taſted Rind, a hard Shell, and within all the Kernel cover'd with a thin Membrane. This Fruit does not follow the Flower in its Place, but grows on another Part of the Tree. This is a Courſe taken by Nature, very frequently in Trees, but more rarely in Herbs, though we ſee Inſtances of it familiar enough.

Thoſe who write on theſe Subjects, mention ſix or eight Kinds of Walnut, and diſtinguiſh the Trees that bear them by ſo many diſtinct long Names, but theſe are only Variations made by Culture; and the Planter who conſiders Timber more than Fruit, needs not regard them. There is in Reality but one Kind of Walnut Tree common in England, and that is the ſame, whether the Fruit be ſmaller or larger, and whether it have a thicker or a thinner Shell. There have of late Years been ſome diſtinct Kinds brought from America, under the Name of Hickery, but though the Nurſerymen raiſe theſe, the Planter has nothing to do with them. If they be equal to the common Walnut Tree in the Timber, they want the Advantage of the Fruit, for theirs is of no Value; and this, though a trifling Conſideration, yet need not be altogether neglected.

There are ſome who prefer the Hickery Wood to our Walnut Tree; but if they are fairly compared together, the English Walnut will be found to have the Preference. The Wood of the Hickery or American Walnut, and eſpecially of the black Kind, is harder than our Walnut, but it has not the Toughneſs: it is often beautifully vein'd alſo, but not comparably to the fineſt of our English Walnut.

The Kind called by our People, the ſmall white Hickery, has the Advantage of quick Growth; but then the Wood is not equal to that of the other Kinds.

I have judged it needful to enter thus far into the Difference of theſe ſeveral Kinds of Trees, to prevent the Huſbandman who intends planting, from being deceived by ſuch as are half acquainted with them, and are always more poſitive than ſuch as have ſearched deeper. He may be told that the Virginian Walnut is a quicker growing Tree, and has a harder Wood than the English, and that may tempt him to plant it in Preference; to his great Loſs. 'Tis fit therefore he ſhould be inform'd, that it is one Kind of this foreign Walnut that is of quicker Growth than ours, and another that has harder Wood: as alſo, that he would never be able to ſell either of the Timbers for English Walnut-tree, to an experienced Cabinet-maker; or to get nearly the Price for them that he may have for the other.

The Walnut Tree thrives very well in a dry Soil, and will bear a gravelly or ſtony one without languiſhing, but its favourite Earth is a deep and rich Loam. We have ſome Grounds in Surrey, where there lies at ſix or ſeven Foot deep, a Bed of a chalky Marle. There are Walnut Trees planted on theſe, and they thrive greatly.

Let the Huſbandman who is about to plant, ſearch after a light but firm Soil for his Walnut Trees. They will rarely deceive his Expectation any where, but it is on ſuch Lands as theſe that they will yield their full Advantage. A cold Clay is to be avoided; nor is the Walnut to be planted where there is too much Moiſture. Its own ſpreading Branches keep the Ground at all Times cool and damp about its Roots, and too much Wet does not evaporate well in ſuch ſhaded Places.

The Timber of Walnut Trees that have grown in a chalky Soil, or in a very light and ſandy Loam is found beſt; and that is always worſt which is yielded by Trees that have grown in the Way of too much Moiſture: this makes the Wood leſs firm, and hurts the Colour.

The proper Situation for the Walnut Tree is a little riſing; the Tops of Hills are too bleak; and the low and flat Grounds are apt to be too damp.

The Walnut ſhould be raiſed from Seed, that is, by ſowing the Nut; and it ſhould always be

sown in the Place where it is to ſtand. The common Practice is to raiſe them in a Nurſery, and remove them at four or five Years Growth into their Places; but this is very prejudicial to the Planter. I am ſenſible that the Nurſery-men will all tell the Farmer that the Wallnut Trees are much better which have been removed, than thoſe which have always ſtood in the ſame Place: but he is to underſtand that there is a Difference in his Deſign from what the Nurſeryman intends. In the tranſplanting a Wallnut the long or tap Root muſt be cut, and this conſequently ſtops the upright Growth of the Tree, making it ſpread into a great Number of Branches at a ſmall Height; and ſuch Trees are beſt for bearing of Fruit, which is all the Nurſeryman thinks of: but it is the Intereſt of the Perſon who plants for Timber, to have the Tree riſe to ſome Height, with a good Trunk; and in order to this it muſt never be removed at all.

The Wallnut Tree ſhould ſtand in a Plantation at five and thirty Foot Diſtance, and may very well be ſet in two Rows forty Foot diſtant from one another. More will not do well, for they will rob each other of Nouriſhment.

When ſuch a Plantation is intended, let ſome good ſound Fruit of the common Wallnut, not the FRENCH, or the fine thin ſhell'd Kind, be collected with Care from a tall Tree, juſt when the green Rind begins to crack.

Let theſe be laid in a large Tub, with the Rind on, and with ſome dry Sand about them, till the next Spring.

In the Beginning of FEBRUARY let the Ground be mark'd out by Meaſure, for the Plantation, and a Hole of two Foot Diameter dug in the Place where each Tree is to ſtand. The Earth being well broken and put into the Hole again, let eight or ten Wallnuts, taken out of the Sand, be carefully ſet in it at equal Diſtances, with the green Rind on, and cover'd three Inches deep with Earth. Then let the Places be cover'd with a few Buſhes, and all left to Nature.

Wallnuts often miſcarry, but from the Number here directed to be ſet in each Hole, there will riſe three, four, or more Trees. Theſe are to be carefully taken up one by one, at different Times, till only one is left in each Spot, and that the moſt thriving and beſt looking Plant.

Great Caution muſt be us'd not to diſturb the Root of the Tree that is to ſtand, in the taking up of the others: they muſt be rais'd very gently; and the Earth cloſed about it when they are taken up, and a little ſprinkling of Water allowed for the ſetting of the Ground thoroughly about the ſmall Fibres.

When the Tree is left ſingle it muſt be defended from Accidents, by Buſhes planted round it, not by paling, as ſome do, for that hinders the free Courſe of the Air; and the Wallnut is found to require it more than any other Tree.

The Planter will remember that he raiſes his Tree for Timber, and that 'tis his Intereſt to carry it up in a good Trunk: but the Wallnut is particular in this alſo, that no Tree bears the Loſs of its Branches ſo ill.

Such Boughs as threaten to ſpread from a ſmall Height, muſt be carefully removed; and all the Care of this Kind muſt be taken while it is very young, for the taking off a Branch of any Bigneſs in the Walnut always endangers the Tree. If that ſhould ever be needful, it muſt be done juſt at the Fall of the Leaf, and the Branches muſt be cut off ſmooth and even, cloſe to the Body: after this the Trees are to be left to themſelves, and will ſoon yield a Profit from their Fruit, which will give the Planter Patience to wait for the Growth of the Timber.

It will be ſeen by the particular Treatment neceſſary for raiſing the Wallnut Tree for Timber, that no general Direction can ſerve for the Propagation of all Kinds of Trees. Each has its particular Nature, and demands more or leſs a particular Management. The Reader therefore will not call us tedious that we have delivered the Method of raiſing each ſeparate; or accuſe us of repeating the ſame Practices for the raiſing ſeveral Kinds, ſeeing thoſe Practices are only the ſame in generals; and vary altogether in the particular Inſtances.

It is neceſſary not only to lay down the right Methods, but to guard againſt the wrong. It is a common Practice in thoſe who raiſe Wallnut Trees from the Nut, to lay a ſquare Piece of Tile under the Nut they plant, at two or three Inches Depth. The Intent of this is to ſtop the great and ſtrait Root, and make it break and ſpread. This is right in the raiſing the Wallnut Tree for Fruit; but altogether wrong when it is intended for Timber, becauſe the long or tap Root, in that Caſe, is more uſeful than all the reſt, and is the very Thing that carries up the Trunk to a due Height.

We have obſerved that the Wallnut Tree for Timber ſhould be planted only in one or two Rows, and that at a due Diſtance: in this Caſe the Tree, being carry'd up to a proper Height in the Trunk, is to be left to ſpread as Nature directs; and never to be lopped. But if any one ſhall chuſe to ſet it among other Timber Trees in a Wood; it muſt be lopped up to a great Height, the Branches being taken off, as already directed, and thus it will fare like the reſt of the Shoots, and grow ſociably among them.

The Wallnut may alſo be planted in Tillage Ground, but at a great Diſtance. Wallnut Trees in Corn Lands ſtanding at a hundred and fifty Foot Diſtance do no Harm. Their Roots penetrate deep for Nouriſhment, ſo that they neither rob the Crop, nor lie in the Way of the Plow. They thrive excellently in theſe Places; the frequent Stirring of the Land contributing greatly to their Growth, and they are a Defence rather than an Injury to the Ground.

Wallnut Trees rais'd in the Manner here directed, ſerve excellently for Avenues, and in other regular Plantations: and when planted merely for Gain, on Grounds of little Value, they are beautiful as well as profitable. The largeſt Plantations of Wallnut Trees any where in ENGLAND, are in SURRY; and the Owners find ſo great Advantage in them, that they take Care to keep up a continual Supply for Deficiencies.

In theſe Plantations the Huſbandman is to take Care that the Soil be not ſandy underneath; and that the Situation do not expoſe them too much to cold Winds; with this Caution the Plantation will never fail, though according as the Soil is more

or leſs favourable, the Growth will be quicker or ſlower.

As the Fruit of theſe Trees, though rais'd for Timber, is not to be neglected, I ſhall caution the Farmer againſt a vulgar Error. 'Tis ſaid that the Wallnut Tree is the better for beating; and this is handed down from Generation to Generation, in Rhymes and Proverbs. But it is altogether falſe. As it would be tedious and difficult to gather Wallnuts by hand, People got into a Cuſtom of beating them off the Branches with Poles; and from the general Practice they came, at laſt, to think it was uſeful to the Tree: but this is altogether an Error. Though beating may be allowable for Convenience, it is not to be commended: and he who has a due Care of his Trees will do well to ſee it be done as gently as poſſible.

A great Quantity of Leaves are uſually beat down with the Fruit, and theſe had better be ſwept away than trampled into the Ground: for there is ſomething in the Juice of the Wallnut Leaf not favourable to the Soil. If, after theſe Leaves and broken ſmall Branches are ſwept away from under the Tree, ſome freſh Aſhes be ſcattered over the Ground, they will greatly aſſiſt both the Tree itſelf, and all that grows about it.

If any other Kind of Wallnut Tree be deſired for Variety in the Plantation, that which is called the black Virginian Kind is the beſt. It will do as well on our Soil as in its own native one: but it is a ſlow Grower, and the Fruit is of no Value. The Wood of this Kind is pretty, being moſtly black and white, but it is brittle.

The Wallnut Tree Timber ſo much valued in France, and called Grenoble Wood, from the Place where it is rais'd in the greateſt Quantity, is no other than the common Wallnut. It bears what we call the large French Wallnut for Fruit, but this does not, in any thing eſſential, differ from our common Kind.

The Time of felling the Wallnut is toward the End of November: and its Value depends ſo much upon the accidental Courſe of the Grain, that it is utterly impoſſible to make a Judgment of it till the Tree is cut down, and it can be ſeen. Wallnut Timber is always of a certain Price with its leaſt Beauty, but when the Grain runs fine it encreaſes the Value beyond Computation.

One thing I ſhall tell the Planter from many Obſervations, which is, that this veining of the Wood is uſually fineſt in the drieſt Soils, and in ſuch Trees as have been longeſt in attaining to their Size. There are Soils ſo dry that this Tree will not thrive in them at all, but where it will live Nature has made this Amends for the Tedioufneſs of the Growth.

The French uſe the Timber of the Wallnut in building, and for the largeſt Works: with us it is, in a Manner, confin'd to two or three Trades, who employ it in ſmaller Works. The Cabinet-makers conſume the greateſt Quantity, and take the fineſt Wood: they uſe it ſometimes ſolid, and often in enlayings. The Part which is not beautifully vein'd is uſed by Coachmakers for the Body of the Coach, as alſo for the Wheels in many Places; and the Stocks of Guns, and many other ſuch Things are made of it.

The fineſt grained Part of the Tree is always that which is neareſt the Root; but in general, where one Part is very good, the reſt has its Beauty, though in an inferior Degree. We ſometimes ſee the Wood brought from Virginia worked into ornamental Things at the Cabinet-makers, and when the Pieces are well choſen it is often very pretty.

When a Wallnut Tree is well grown it affords a great Quantity of Timber; and every Part of that is thus of certain Sale, though ſome at a larger Price than other; ſo that taking in the Benefit of the Fruit, which in this Conſideration is to be underſtood as an accidental Advantage, no Tree is more profitable.

CHAP. XXXVIII.

Of the Horſe Cheſnut Tree.

THE Horſe Cheſnut is cultivated more for its Statelyneſs and Beauty, than for the Value of its Timber: however, as it is a quick Grower, the Quantity will, in ſome Degree, make Amends for the Defect of Goodneſs; and as there are Places where it will thrive, that will ſcarce do for any other Trees, it may be worth the Huſbandman's while to be acquainted with it, that he may uſe it on proper Occaſions.

It is a large Tree, very regular in its Growth, and at its flowering Seaſon of uncommon Beauty. The Bark is of a deep brown and rough, the Wood ſoft and whitiſh. The Leaves ſtand ſeveral together at the End of a ſingle Foot Stalk, dividing like Fingers. The Flowers are white, with a bluſh of red, and grow in Spikes, the Fruit is contained in a prickly Huſk, and is large and brown.

The Nurſerymen raiſe Horſe Cheſnuts with ſtrip'd and blotch'd Leaves, white and yellow, but theſe are only Varieties of the common Kind. The Tree is a Native of the Eaſt, but it bears in our Climate perfectly well, and flouriſhes as if it were originally of our Growth.

The proper Soil of the Horſe Cheſnut is a light rich Earth; but it will grow in ſandy, gravelly, or ſtony Land; and particularly where there are large Beds of Sand underneath, which will not ſuffer other Trees to thrive. In theſe Places it will be profitable to plant the Horſe Cheſnut; and it will do whatſoever be the Situation; though its moſt favourite one is the Side of a Hill.

The Horſe Cheſnut may be propagated by Layers or Suckers, but it is much beſt to raiſe it from Seed. This may either be done in the Nurſery, or in the Places where it is to remain, but the latter is much the better Way. The Ground is to be marked out for this Purpoſe, and a Hole opened at every thirty Foot Diſtance: into theſe Holes, when fill'd up again with their own Earth, are to be put the Seeds, gathered in their State of Maturity, from a flouriſhing Tree. Four or five ſhould be put into each Hole at a Diſtance one from another, and when they have ſhot, the worſt Plants are to be removed, leaving only one at laſt to grow into a Tree. Theſe are to be trim'd up till the Boughs will be out of the

the Reach of Accidents, and then left to Nature. They uſually grow of themſelves very regular.

The quick Growth of the young Branches of this Tree has ſurpriſed many. At the ſhooting Seaſon they will all uniformly grow an Inch in a Day and Night: but this will appear the leſs wonderful, as we examine the Tree more ſtrictly; for we ſhall find that the whole Growth of a Year is performed in about eighteen or twenty Days at this Seaſon: all that is done afterwards being only the giving theſe young Shoots Strength and Firmneſs.

The Horſe Cheſnut, by its own natural Growth, becomes pyramidal, being largeſt at the Bottom, where the Branches begin, and ſmaller all the Way to the Top, but it does not terminate there in a ſharp but blunt Point.

As the Tree is thus regular in its Shoots, there is no Need of lopping to bring it into Form. The Time of felling it is during the whole Winter: but it is of little Value, more than for the Fire. In ſome Places they make the Implements of Huſbandry of its Timber; and if there were not Plenty of other Kinds, it would probably be more enquired after. The Branches make very good Faggots, and the Trunk cleaves into Billets, and it burns better than any other of the ſoft Woods: though not ſo well as the hard Kinds.

The Fruit has a pretty Appearance, but is of no Value: abroad they give them to Horſes and other Cattle in their Provender, partly as Food, and partly as a Medicine againſt Diſorders in their Lungs; but we pay no Regard to them, though there is no doubt of their being a wholeſome and good Nouriſhment.

CHAP. XXXIX.

Of the Cheſnut Tree.

THIS is a Tree very much ſuperior to the former in every Reſpect; the Timber being excellent for many Uſes, and the Fruit pleaſant and wholeſome. The other has been called by the ſame general Name of Cheſnut, becauſe of ſome Reſemblance of the Fruit in Colour and Shape, and in the outer Covering; but the Trees are altogether different in every other Reſpect.

It is a tolerably large, but not a beautiful growing Tree. In that Reſpect the Horſe Cheſnut has entirely the Advantage, as alſo in the Beauty of the Flowers: but the Leaves of this are very handſome, they are large, long, of a fine bright Green, and indented beautifully at the Edges: they ſtand ſingly, not ſeveral upon the ſame Stalk. The Bark of the Cheſnut Tree is brown and tolerably even, the Wood firm and dark coloured. The Flowers are ſmall and inconſiderable, they hang in Strings: the Fruit is the common Cheſnut which we eat: it grows upon a different Part of the Tree from the Flowers, and has a rough or prickly Huſk. Two or three Cheſnuts are contained in each Huſk.

There is but one Kind of this Tree that the Planter is to regard, but that is very worthy of his Notice, becauſe the Fruit is valuable as well as the Timber. Our Nurſerymen raiſe a ſmall Kind from Virginia, called the Chinquapin; and they ſtain the Leaves of the common Kind; but the little Sort is not worth planting, and the ſtrip'd Leaves of the other are only an accidental Variety.

It is a great Advantage in the Cheſnut Tree, that it will grow in almoſt any Soil or Situation, It naturally thrives beſt in a ſandy Loam, on the Side of an Hill, but it may be rais'd in gravelly, ſtony, or chalky Ground; and will ſtand the ſtrongeſt Winds in the higheſt Situation, for it roots very deep, and does not carry ſo tall and large an Head as many other Trees.

Too much Moiſture in a Soil will hurt the Growth of the Cheſnut; and it will much better bear a dry and harſh Land; but it will live almoſt any where; and bear great Quantities of Fruit in the worſt Land. Even wet is not an utter Enemy to the Cheſnut Tree, unleſs when it is detained about its Roots. A moiſt Gravel is a very favourite Soil for it: the clayey Bottom of a Soil that will not let Water run off, is the moſt deſtructive of this, and of other Trees that don't affect Moiſture, for it chills and rots their Roots.

The Cheſnut is to be rais'd from Seed; and the Fruit of this Tree ſo far enters into the Conſideration as an Article of Huſbandry, on this Occaſion, that a great Part of the Expectation of good Trees is founded on the Choice of it.

The Cheſnut ripens its Fruit very well in England, but the Planter ſhould not raiſe his Stock from theſe. We import yearly a great Quantity of Cheſnuts from Spain and Portugal, for the Service of the Table; and theſe are to be prefer'd greatly to thoſe of our own Growth for the ſetting for Trees.

Let the Perſon who intends to raiſe Cheſnuts purchaſe a Quantity of theſe at the Seaſon of their coming over, which is in Winter. Let him buy twice as many as he will have Occaſion to uſe; and lay them carefully up till Spring, in ſome Place where they will neither be too dry nor too moiſt, and where Vermine cannot come at them.

In the Beginning of February let him prepare to ſet them in the Ground. But in order to this let him examine his Parcel, by throwing them all into a Tub of Water. Part will ſink to the Bottom, and part will ſwim upon the Top of the Water. Thoſe which ſwim are naught, the others are ſound.

They may be rais'd either in Nurſeries, or in the Places where they are to ſtand. But as the Fruit is ſome Conſideration in this Tree; and the Timber is not ſo valuable as in ſome others, it may be as proper a Method to raiſe them in the Nurſery, and tranſplant them afterwards. In general, when the Timber only is regarded, and fine Timber bears a great Price, the beſt Method is to raiſe the Trees in their Places, but in thoſe which bear Fruit, it is as well to raiſe them in Nurſeries.

To this Purpoſe the Place for the Nurſery being choſen in a poor Ground, let Trenches be opened in the ſecond Week in February, four Inches deep, and ſix Inches aſunder. Let the Cheſnuts be planted regularly in theſe, one every four

four Inches, with the Eye uppermoſt; and let the Earth be drawn over them.

Half a Dozen of theſe Trenches muſt be made, and then a Space left by way of Alley, to get between and clean them; and then another Bed of ſix Rows made as before; thus proceeding till ſuch a Quantity of Cheſnuts are planted as will ſerve for the intended Trees; and for a Supply to ſuch as may want in the Neighbourhood; for there are uſually ſome who will be glad to buy the young Trees at a ſmall Price, which takes off from the Expence of the Nurſery.

When the Cheſnuts are planted, Traps muſt be ſet all about the Ground for Vermin, elſe they are ſo delicious a Bait, that they are often devour'd.

They will appear above Ground in two Months, and they are then to be kept clear of Weeds, and to ſtand two Years. At the End of this Time the young Trees muſt be taken up and planted at two Foot Diſtance, in Rows a Yard aſunder. In this removing, the long tap Root is to be cut off; and Care taken not to injure the others.

The beſt Seaſon for tranſplanting them is early in MARCH, and from this Time Care is to be taken of their growing upright and ſtrait, by trimming off the Side Shoots; or where they will ſpread too low, by cutting them off down near the Ground, taking Care to do it where there is a Bud. They will ſhoot up from this a ſingle ſtrait Shoot, and become fair and flouriſhing Trees.

After they have ſtood four Years in this ſecond Place, that is, when they are ſix Years old from the firſt ſowing, they may be removed into the Places where they are to remain.

The Cheſnut is a very good Tree for Avenues, for Clumps in Parks, and for many other Kinds of Plantations, where the Beauty of the Leaf, and Value of the Fruit are regarded. They may be ſet at about twenty Foot Diſtance, and will afford a conſiderable Quantity of Timber.

This is uſed by Joiners and Cabinet-makers. At one Time 'twas a Cuſtom to employ it in the Way of large Timber for Beams in Houſes. At preſent 'tis more uſed in ſmall Works, as for Tables, Bedſteads, Chairs and Cheſts; in which it makes a pretty Appearance.

In ſome Places they make Wine Caſks of it, and it is ſaid to give leſs Taſte to the Wine than many other Woods.

It has much the Appearance of Oak when dry'd and cut out; and the ſmaller Purpoſes of Oak are anſwer'd by this in common. They make Laths of it as regularly as of the Oak, and the Workmen purchaſe them at the ſame Price. In thoſe old Buildings where Cheſnut Timber has been uſed inſtead of Oak, many a Workman has been miſtkaken, and paſſed it over as Oak on his Examination. It will bear to lie continually in Water, and is therefore uſed in Mills and Sluices; but where it is at Times wet, and at others dry, it comes to nothing.

The Timber of the Cheſnut is ſeaſon'd by dipping it in boiling Oil; and if after this it be pitched over, there is no End of its laſting.

When the Cheſnut is planted in Coppices, or cut down in the Manner of Coppice Wood, it affords ſtrait, ſtrong and even Poles, that are fit for the Service of Hop Planters, and on many the like Occaſions. But it muſt be acknowledged, that the Timber, although it has the Appearance of the Oak, has not its Virtue of long remaining ſound, for it is very apt to grow rotten: and will often have a very fair Appearance on the Outſide, when there is only Duſt deep within.

CHAP. XL.

Of the Service Tree.

THE right Service Tree is a tall and beautiful Tree, and very well worth planting for its Timber. There are two or three other Kinds which are called by the ſame general Name, and they agree in the Nature of the Wood, as well as in the Flowers, and the Shape of the Fruit; but they vary in the Shape of the Leaf, and the Degree of Goodneſs. Theſe other Kinds are diſtinguiſh'd by the Names of the Service Tree, with the Fruit red in the Middle. 2. The ſhort fruited Service; and, 3. The wild Service or Quick Beam.

The firſt is the moſt valuable, and the two next come neareſt its Nature. The laſt differs more, and as it is not generally accounted of the Service Kind, but called by a diſtinct Name; I ſhall treat of in a Chapter by itſelf. The Flowers of the others are much alike, they appear early in Spring, and the Fruit is very rough to the Taſte till thoroughly mellow. All the Summer it makes a beautiful Appearance.

The beſt Soil for the Service Tree is a tough and firm Loam, with ſome rich Earth among it. Such are very common toward the Foot of Hills, or on any gentle Aſcent, and theſe are the beſt Situations alſo for this Tree. When the Soil is too light, the Tree grows very ſlowly; and when it is too dry, the Fruit is ripen'd very poorly, neither do the Leaves ſtand their Time. When the Service is judiciouſly planted, it grows quick, and anſwers very well to the Huſbandman; but when the Plantation is made at random, none anſwers worſe. Few know its Value, becauſe few have given it a fair Trial; nor is its Timber ſo much known, or ſo common to be had, as it ought to be, for this very Reaſon. He who will fall into the Method of raiſing theſe Trees, will do a Service to the Publick, as well as to himſelf; for there needs but a beginning to incite others, and the Conſequence would be a ready Market for the Timber, and it would prevent the Importation of a great deal of foreign fine Wood; which, however called by ſounding Names, is inferior to that of the Service Tree in Beauty, and in Value.

The Service may be raiſed from Seed, but the better Way is by Layers, which take Root very freely, and are naturally produced in great Abundance. The Method of raiſing Trees this Way,

Way, has been laid down under the Article of the Elm, and need not be repeated. Thoſe who have a mind to raiſe them from Seed, muſt ſow them in ſhallow Trenches, in a Nurſery, and keep them clear from Weeds. At two Years old they muſt be planted out at a Yard Diſtance, and three or four Years after that, be ſet where they are to ſtand. Such as want only a few Trees, may conveniently enough raiſe them from Suckers, which grow about the old Trees in great Abundance. Theſe are to be tranſplanted early in Spring, and they take Root freely.

Which ever Way the Service Tree be rais'd, it ſhould be carefully trim'd up for the firſt eight or ten Years, that it may not ſpread into Branches till a certain Height, when there will be a handſome Trunk for Timber. After this it is beſt left to itſelf.

It is a very proper Tree for Avenues, Clumps and Hedge Rows, and 'tis great Pity that it is not more frequent. Its Beauty ſhould be an Inducement to the Gentleman, and its quick Growth and valuable Wood to the Huſbandman.

The Grain of the Wood is very beautiful, and its Variegations often exceedingly pleaſing. It is excellent for the Cabinet-maker, the Turner, and the Carver, being ſoft, and yet ſufficiently firm. The Stocks of Guns are ſometimes made with it, and Eſcrutores, Chairs and Tables. It alſo ſerves for many of the ſmall Works in Wood; and when properly oil'd and varniſh'd, imitates and ſupplies the Place of the foreign Woods in ſeveral of the ornamental Pieces of Furniture, and nice Inſtruments.

CHAP. XLI.

Of the Quick Beam.

THE Quick Beam, or, as ſome call it, the Quicken Tree, or according to others, the wild Service, or the flowering Aſh, for it has all theſe Names, is properly a Kind of Service Tree, though, from its particular Form and Uſes, treated of here ſeparately. It is a beautiful but ſmall Tree, being one of the leaſt of thoſe that are accounted Timber Trees, or planted for that Purpoſe.

The Bark is pale and ſmooth, the Leaves are beautifully form'd, each being compoſed of many ſmaller, which are long, narrow, and finely dented at the Edges. The Flowers ſtand in great Bunches at the Ends of the Branches, and are whitiſh, large and handſome: and after theſe come beautiful Berries red like Coral.

This elegant little Tree is Native of ENGLAND, and is a great Beauty and Ornament to our Coppices and Hedge Rows, in thoſe Counties where it is moſt frequent. Its fair Appearance has occaſion'd its being taken alſo into Gardens, where it makes a fine Figure in the Wilderneſs Quarters.

The beſt Soil for the Quick Beam is a light and dry Loam; and it grows beſt on a ſomewhat riſing Situation. No Tree is better ſuited to thrive in Hedge Rows, where the Soil is light and dry. It roots itſelf very firmly; and ſhoots up in a moderate Time to its full Stature.

The beſt Way of raiſing the Quick Beam is from Seed. The Berries are to be gather'd when full ripe, and ſown after they have been ſpread a Fortnight in a dry airy Garret. They ſhoot up very regularly and freely, and ſhould be removed from their firſt Bed to ſome other Part of the Nurſery at two Years Growth, and planted at two Foot Diſtance. Three or four Years after this, they are fit to be tranſplanted to the Places where they are to ſtand; and a ſmall Nurſery will thus, with little or no Trouble, raiſe ſuch a Quantity as will ſtock a large Piece of Ground; where being ſet in Hedges, or the Banks of Coppice Woods, and other ſuch Places, they will quickly grow to ſome Value.

Thoſe who would only raiſe a few Trees, may take up Suckers from about the old ones, for they riſe in Abundance, and grow freely.

The Quick Beam ſhould have very little trimming or lopping; for, as it is not to be carried to a large Tree, 'tis beſt left to Nature, the Branches of themſelves growing with a pretty Irregularity.

Few of our Trees are more hardy than the Quick Beam, or better bear the cold Winds: ſo that the Farmer who has a light Soil in ſuch an Expoſure, as few other Trees will bear, may plant this, which will be a Shelter to his Grounds, and after a few Years may be felled to Advantage, he taking Care to raiſe young Trees between the old ones by way of Supply.

The beſt Time for felling it is in NOVEMBER, for at that Time the Wood is in a Manner all Heart, and is more laſting than ſuch as is cut at other Seaſons.

The Timber of the Quick Beam is tough, and not heavy. It is uſed in making all Sorts of Carriages, from the Wheel-barrow to the Coach. Where it is in Plenty, the Farmers make moſt of their Implements of it; and it anſwers their Purpoſe ſo well, that it would be worth their while to plant it much more generally than they do for their own Service.

We have before ſet down the Methods of raiſing the more valuable Kinds of Timber Trees, but it is fit the Huſbandman ſhould underſtand the Nature, and the Culture of all; that where one Kind will not do he may plant another, ſo that no Part of his Ground may be without its Uſe.

CHAP. XLII.

Of the Birch.

THE Birch is a Tree of a moderate Size, quick Growth, and very pretty Appearance. It alſo anſwers many Purpoſes in the Affairs of Life, though not of the moſt important Kind; and produces the Owner a tolerable Profit, though its Price come not near that of the ſeveral large and more conſiderable Timber Trees.

Its Bark is ſmooth and gloſſy, its Leaves are

are roundiſh and of a fine green; the Twigs are reddiſh, and very ſlender and knotty: well known to School-boys. The Flowers are ſmall, and hang in Catkins like thoſe of the Hazel. The Fruit grows on other Parts of the Tree, and is a little light Cone. There is no Choice of Kinds in the Birch, for we have but one: it is remarkable of this Tree that it naturally caſts its outer Bark every Year.

The Birch Tree is a Native of our Country, and it ſeems indifferent to all Kinds of Soils and Situations; it will live on ſandy Hills, and in the rotteneſt Bogs: and it will ſtand in Hedge Rows, though its beſt Situation is in Coppice Woods. No Soil is too barren for it: whether it be gravelly, ſtony, chalky, or whatſoever, the Birch thrives upon it. But though it will do on any Ground, 'tis fit the Huſbandman be inform'd, that for quick Growth, and the beſt return of Profit, he ſhould plant it in the damper Parts of ſome Coppice Woods, where it grows up quickly to ſuch a Size as to be uſeful.

The Birch Tree is beſt raiſed from Suckers. Theſe are produced in great Plenty about the old Trees; and are to be taken up in February, and planted where they are to remain. They will take Root freely, and ſhoot quick: but in order to make them grow in the beſt Manner, the Planter ſhould, when they have ſtood two Years in their new Place, cut them down four Inches from the Ground, and watch the new Shoots. He is to reſerve the faireſt and ſtraiteſt of theſe; rubbing the reſt off: and in this Manner the Birch with a little Care at Times to prevent its ſending out Side Shoots too low, will riſe to a tolerable Tree. But it is not worth while to keep it to any great Growth, for the Timber brings but a poor Price.

The beſt Time for felling the Birch is the End of November; for no Tree abounds ſo with Sap in the growing Months, and 'tis beſt to cut it when that is moſt down.

The Timber is light, but has ſome Strength. It is uſed for making light Carts and Yokes, and many other Things in the Farmer's Way, for it works eaſily, and is tolerably laſting. Turners uſe the large Wood for Bowls, Diſhes and Trenchers: and the leſs uſeful Part makes excellent Charcoal. Brooms are made of the Twigs: a great deal of Birch is raiſed for this Purpoſe, and near large Towns, yields a very conſiderable Profit.

When the Birch is intended for this Uſe, it is to be planted juſt as before directed, only when it has ſtood one Year it is to be cut down to the Ground, or within a few Inches of it; and all the Shoots are to be ſuffer'd to grow. Theſe ſoon become fit for Hop-poles, and other ſuch Uſes, and furniſh Abundance of Twigs for the Broom-man.

Hoops are in ſome Places made of the Poles, and Bakers Panniers frequently of the Timber. Smallcoal is generally made of the Bruſh Wood of the Birch; though any other light Wood anſwers the ſame Purpoſe. The Antients wrote upon the Bark of the Birch inſtead of Paper.

Laſtly, We are to mention the Uſe that is made of the Sap of this Tree for Wine. It bleeds the moſt freely of all our English Trees, and its Juice is not only the moſt in Quantity; but the beſt of any for this Purpoſe. The Time of tapping the Tree is in the Beginning of March, the Juice which runs freely from the Wound is of a pleaſant Taſte, and being work'd up with Sugar, or with Honey, which is the better Way, makes that agreeable Liquor called Birch Wine, or Birch Mead.

There are two Ways of getting the Sap; the one by boring a Hole in the Tree; and the other by cutting off the Ends of ſome of its Branches. When a Hole is bored in the Trunk, a Piece of Chip is to be ſet againſt it to guide the Sap into the Veſſel put to receive it; when the Ends of the Branches are cut off, they are to be let into Quart Bottles, a great Number of which may be hung upon one Tree, and will quickly receive their Quantity of the Sap.

The Sap runs moſt freely in the middle of the Day, and in the warmeſt Weather. A South or Weſt Wind ſets it a going; and a North or Eaſt ſtops it, or makes it drip much more ſlowly. This, when made into Wine, is a pleaſant and wholeſome Drink, and has a conſiderable Effect in ſweetening the Blood; and curing the Scurvy.

CHAP. XLIII.

Of the Horn Beam.

THE Horn Beam is a beautiful and regularly growing Tree. Its Bark is brown and tolerably ſmooth, and the Wood firm. The Leaves are ſhort and indented at the Edges, they are ſomewhat like thoſe of the Elm, but of a more beautiful Green. The Flowers are ſmall and inconſiderable. They hang in Catkins like thoſe of the Hazel; and the Fruit, which is dry and light, grows on a different Part of the Tree.

There are four Kinds of this Tree raiſed in Nurſeries. 1. The common Horn Beam. 2. The Hop Horn Beam. 3. The flowering Horn Beam; and, 4. The Horn Beam with ſtriped Leaves: but the Huſbandman who would plant for Advantage, has nothing to do with any of theſe except the common Kind.

The Horn Beam is an extreamly hardy Tree, it will grow in the worſt Soil and bleakeſt Situation. For this Reaſon it is very proper to be planted on the Tops of cold Hills, and in Places ſo expoſed, that other Trees will not grow on them. It will thrive very well in Hedges, and in Woods; and is excellent for Clumps in the bleakeſt and worſt Parts of Parks, and it every where engages the Eye by its Beauty.

The beſt Way of propagating the Horn Beam is by Layers, the Directions for which are laid down under the Article Elm. It may alſo be raiſed from Seeds, but this is a more tedious Method, and the other does as well. If the Seeds are prefer'd, they muſt be gather'd in September, and ſown three Weeks or a Month after, laying them in the mean time in a dry airy Place. They will ſometimes come up in five or ſix Months, ſometimes they will lie till the

the following Spring. They are to be thin'd ſoon after they appear, and kept clear of Weeds, and at two Years old to be removed to another Part of the Nurſery, where they muſt be planted at a greater Diſtance, and three or four Years after they are to be finally removed, and ſet where they are to remain. But the Method by Layers is much more expeditious, and the Trees grow as beautiful that Way as the other.

The Horn Beam is very fit to be raiſed for the Garden as well as Field; for ſcarce any Tree makes a more beautiful Hedge. When it is intended for this Uſe, the Side Shoots are to be left on, and it is be train'd up flat; but when planted for Timber, it ſhould be trim'd up that it may grow with a good Trunk. The Hop Horn Beam is better for the Garden than the common Kind, becauſe this does not drop its dead Leaves ſo readily, but they hang on in Winter, and are an ill Sight; but the common Kind is beſt othetwiſe. Its Uſe in Hedges is very great, becauſe it bears clipping, riſes to a great Height in a moderate Time, and will be thick and cloſe at the Bottom when it is twenty Foot high in the Hedge. It roots alſo very firmly, ſo that it ſtands the Force of Winds; and is a fine Shelter to the other Growths.

Its Leaves, beſide their Beauty both in Shape and Colour, have this Advantage over moſt others, that they appear earlier in Spring, and continue longer green in Autumn. One of the greateſt Beauties of the Gardens at Versailles, is the Height, Beauty, and Regularity of the Horn Beam Hedges.

The Farmer will find his Account in it whether he plant it in Hedges, in Coppice Woods, or on waſte Grounds; and whether he train it up for a Trunk, or cut it for Shrowding. In general he ſhould carry it up for Timber in his better Soils, and ſhrowd it where the Ground is very poor. In this Caſe the Branches ſhoot very quick, and afford good Fuel; and the Trunk cut down at a proper Time, uſeful Timber. In Coppice Woods it ſucceeds very well, and bears the dropping of the Trees left for Timber better than moſt others.

The ſmall Wood of the Horn Beam is good for Fuel, and makes an excellent Kind of Charcoal. The Timber is of a pale Colour, firm and ſtrong; but harſh, and of an uneven Grain. It is employ'd for many Purpoſes where Strength is requir'd, more than Beauty. Nothing is better for Mill Coggs: the Heads of Beetles and Mallets are alſo made of it; and the Turners uſe it ſometimes for the ſtronger and coarſer Kinds of their Ware. The worſer Parts of the large Wood ſplit make excellent Billetting, burning pleaſantly and laſting.

CHAP. XLIV.

Of the Maple.

THE Smallneſs of the Maple does not prevent it from being a very valuable, as well as a beautiful Tree; and 'tis a Wonder that more Notice is not taken of it by thoſe who have any regard to planting.

The Tree we call the Sycamore, as already obſerv'd, is only a large Kind of Maple; and this which we call by the Name of Maple, reſembles it accordingly in Flowers and Seeds; and, in ſome Degree, even in the Leaves. The Bark of the Maple is browniſh and very rough: the Leaves are broad and deeply divided at the Ends. The Flowers are ſmall and inconſiderable, and the Fruit reſembles that of the Sycamore, being a Kind of Keys, only ſmaller and fewer in a Bunch.

In the Nurſeries they raiſe ſeveral foreign Kinds of Maple, as the Norway and Virginian Sorts; but the English Planter has no Occaſion to regard any except the common Kind, which is frequent in Hedges, and is very worthy of his Care to make it more univerſal.

The beſt Soil for the Maple is a good vegetable Mould, or mellow Earth, with ſome Admixture of Sand, for it does not thrive either in too tough or too light Soils: but it will live in almoſt any. The Situation that moſt favours its Growth, is a little Elevation. In Hedge Rows on the Sides of Hills in a good Mould, we ſee the Maple very luxuriant. But tho' the Hedges are its common Situation, it will live very well in Coppices and Woods, and, with Care, may be brought to a much greater Value than it uſually is.

The Maple is beſt raiſed from Seed; for it grows freely, and bears tranſplanting. The Keys are to be gather'd when perfectly ripe; and it is beſt to pick them from the largeſt and moſt flouriſhing Trees. They are to be ſpread upon the Floor of a dry airy Room for eight or ten Days, and after that ſown. Any waſte Piece of Ground does for a Nurſery, the poorer the better; and they are to be ſown pretty thick in Trenches, drawn acroſs the Ground at ſmall Diſtances, and lightly cover'd with the Mould.

They will ſhoot up early the next Spring, and require very little Care afterwards. At a Year and half old they muſt be planted out at two Foot Diſtance, and three Years after that is a good Time to remove them to the Places where they are to ſtand.

We have already named the moſt favourable Soil and Situation for it; but the Planter needs not ſtint himſelf to that ſingly. Let him avoid wet Places, and for the reſt he cannot do much amiſs; Chalk, Sand or Gravel will feed the Maple! only let him obſerve that in theſe poorer Soils, he muſt not expect it to grow to any Size. When he has a right Soil and Situation, let him train it up to a Tree.

To this Purpoſe when it is removed into the Place where it is to ſtand, let him take off all large Side Shoots, leaving only a Head and a few little Branches to draw up and detain the Sap in the Trunk. Thus trimming it up for a Tree, he will bring it to better Form than it is commonly ſuppoſed capable of, and will greatly encreaſe its Value.

He is never to ſhrowd the Maple, or favour its ſpreading; for the Droppings from it are hurtful to all Things; and particularly a clammy Dew that gathers upon it.

The Maple is but a ſlow growing Tree; but it makes Amends in the Beauty of the Timber,

the finer Pieces of which are of conſiderable Value. Its Keys make a pretty Appearance when ripe, and it would, for that Reaſon, have a Place in Gardens, but that the foreign Kinds have the Preference.

The Wood of the Maple is of a cloſe and beautiful Grain: it cuts eaſily, and has a Firmneſs that holds it together in ſmall Works, whence it is greatly valued by the Turners and Carvers. And when it happens to be vein'd, as is frequently the Caſe, it is uſed for fine Works by the Cabinet-makers, and in inlaying, it is then called the curl'd Maple, and Peacock-tail Maple.

They make Gun Stocks, and ſometimes Knife Handles of it; and it is turned into Cups, Spoons, Trenchers, and Diſhes, all very beautiful.

The Timber of the Pollard Maple is moſt apt to be curl'd and variegated; but it grows hollow very ſoon in this Form, and there is no depending upon its Soundneſs, except when 'tis carried up to a ſtandard Tree. In Hedges it is brittle, but it will grow after breaking or cuting, if but the ſmalleſt Piece remain with any Bark upon it.

The Maple Wood has heretofore born a great Price, but the Uſe of foreign Woods has let down its Credit: the Romans held it next in value to the Cedar. The knotty Parts of the Tree are moſt beautifully vein'd; and what is called by our Cabinet-makers French Maple, is no other than the irregular growing Parts of the Trunk of an old Maple, that happens to keep ſound. That Part of the Wood which grows near the Root of an old Tree is alſo very beautiful: and ſometimes there ſtand out large Knots from the Surface of the Trunk, which, when cut through and well poliſhed, have a moſt elegant Variety of Veins and Marblings.

The Norway Maple is ſo hardy that it may be cultivated here without Difficulty, and it will be eaſier rais'd to a large Tree than our common Kind: but its Wood has not that Excellence. In Appearance this more reſembles the Scycamore than the common Maple; and it has an Advantage over it for Plantations near Houſes, that the Leaves remain more entire. The ſweet Juice that gathers about Sycamore Leaves entices Inſects, which eat them to Pieces, but the Leaves of the Norway Maple are ill-taſted and therefore eſcape.

In ſome Parts of North America, they make Sugar from the Juice of the Maple: and the ſame has been done here from the Juice of the Sycamore, which, as before ſaid, is only a large Maple: it has been try'd and found to yield it in large Quantity.

CHAP. XLV.

Of the Cherry Tree.

THE Cherry Tree, though cultivated in general for its Fruit, is not to be deſpis'd on Account of its Timber; and might be worth planting alone for that, were there no other Advantage attending it. It is a large and tolerably well growing Tree, when carried up to an Height by trimming; though the uſual Intent of raiſing it being for the Fruit, it generally is made to ſpread into Branches.

The Bark of the Cherry Tree is brown, and tolerably ſmooth; the Leaves are large, longiſh, and ſhining, the Flowers are large and white, or rediſh, and the Fruit is round, or nearly of that Shape, with a Kernel included in a hard Stone. We have a great many Kinds of Cherry, but there are two principal, the black and the red; and to one or other of theſe all the other Sorts are to be refer'd; the black Cherry being ſmall and the red large. The Heart Cherry is of the red Kind, and the Variety of others nam'd from the Fancy of Gardiners and Nurſery-men do not deſerve the Notice of the Huſbandman, who means to plant the Cherry as a Timber, as well as Fruit Tree.

The black Cherry naturally riſes to a tall and well-ſhaped Tree, and the red may be brought to it: and theſe may be rais'd without any particular Trouble, and will yield Profit enough to the Planter. The others require all the Arts of the Gardiner; and we ſhould carry the Farmer out of his Way to lead him to them. All thoſe fine Kinds are cultivated by budding or grafting them into the wild black or red Cherry Stock; and the Gardiners tell us this is becauſe thoſe are free Shooters; this is enough to ſhew the Huſbandman that it is his Intereſt to plant them: for the free ſhooting, and quick Growth of a Tree are to him Articles of the greateſt Conſequence.

The beſt Soil for the Cherry is a Loam; this Tree does not require a rich Earth, but it will not bear the two Extreams of Clay or Sand. In the clayey Soils its Roots are ſtarv'd, and in the ſandy they are burnt up, but on any other Ground it will grow very freely. Too much Dryneſs or too much Moiſture are equally Enemies to the Cherry Tree. But it will ſtand and grow to Timber under many of theſe Diſadvantages, though they affect the Fruit.

The Cherry will grow in any Situation, but it does not thrive well when too much expoſed, as on the Tops of bleak Hills. It is obſerved to ſhoot the quickeſt, and arrive at its Bigneſs ſooneſt, in Soils where there is a good Degree of Moiſture; but the Timber is moſt valuable where it has grown on a dryer Ground.

The Cherry is to be propagated by ſowing; and the beſt and moſt advantageous Kind is the black. The Stones ſhould be ſaved from ſome of the beſt Fruit of a large and tall Tree, and us'd ſoon after they are gathered; they ſhould be ſown in a Piece of poor Ground, in Trenches, and covered two Inches and an half with the Mould. When they ſhoot, the young Trees are to be thinn'd, and kept clear from Weeds, and at a Year's Growth they ſhould be removed into a larger Bed, and planted at eighteen Inches Diſtance, in Rows two Foot and an half aſunder. Thus they are to ſtand till they are large enough to remove into their proper Places.

They may be planted in Hedge Rows, Orchards, Parks, or Warrens, and the proper Diſtance is about five and thirty Foot; the beſt Way is in Rows, and theſe ſhould be forty Foot aſunder. Thus they may be train'd up to uſeful Trees of

Timber, and at the ſame Time afford a conſtant Profit from the Fruit.

The Cherry Trees in many Parts of ENGLAND ſtand in the Hedges, and where the Property is ſecured by Cuſtom it is a very good Method; but in Places where idle People will make free with the Fruit, they will be broke to Pieces in the gathering it; and the Hedges ſpoiled all about.

It is better, in theſe Places, to plant a poor Field with them by way of Orchard, and the Ground may be tilled between them, eſpecially while they are young, as much as if it were clear. The only neceſſary Caution in ſuch a Plantation is, that it be defended from weſterly Winds, for they are always hurtful to this Tree. The more the Trees are carried up for Timber, the longer the Ground may be tilled between them; for when they are ſuffer'd to ſpread at a ſmall Height, as is uſually done when they are planted only for Fruit, they ſoon ſhadow the whole Ground, and injure the Growth of any thing ſown upon it by their Drippings.

There is this farther Reaſon for carrying the Cherry Tree up for Timber at preſent, that the Fruit bears ſo ſmall a Price it ſcarce pays the Charges of gathering in a bad Year; and affords very little Profit even in the moſt favourable.

Both the black and the red Cherry, properly train'd up for Timber, by cutting off the young Branches that would ſpread too much, and carrying the Tree to a Top, will grow large, regular, and beautiful. They make a very good Appearance in Avenues, and other regular Plantations, when rais'd for that Purpoſe; for though the Cherry in Orchards is a very ill looking Tree, this is not ſo much in its own Nature, as the Manner of cultivating it. A well grown Cherry when in Bloſſom, makes an elegant Appearance, as alſo when in Fruit, where theſe are ſuffer'd to hang undiſturbed.

One thing is very eſſential in the preparing the Cherry Tree for Timber. When it is tranſplanted from the Nurſery, the uſual Way is to cut off the large down-right Roots: this is right when it is rais'd for the Fruit, becauſe it prevents the Trees riſing in Height, and makes it ſpread into Branches: but juſt the contrary of this is the Deſign when the Cherry Tree is rais'd for Timber; and therefore the long Root is, in this Caſe, to be left entire at the Removal, and the top Shoot never ſhorten'd or injur'd.

Thoſe who want only a few Trees may raiſe them from Suckers, which grow in Plenty about the Roots of the old ones, but it is a much better Way to ſow the Stones, and the Trees are always the fairer.

We are accuſtomed to ſee certain Kinds of Cherries cultivated in certain Places, and ſome have ſuppoſed they thrive particularly there; but there is nothing more in this, than that Cuſtom has become the Law of the Huſbandman; and he plants the Kind he ſees planted by his Neighbours. Red Cherries are cultivated in KENT in ſuch Plenty, that they have obtained a Name from the Place; and in the ſame Manner black Cherries ſeem peculiar, in a Manner, to HERTFORDSHIRE. But I have ſeen as good black Cherries in KENT as in that County; and have eaten KENTISH Cherries in HERTFORDSHIRE as good, and from as fair and flouriſhing Trees, as any in the Country from which they are named.

The red Cherry requires a ſomewhat richer Soil than the black; and the Huſbandman who intends to raiſe theſe Trees ſhould guide himſelf accordingly; not planting black becauſe in one County, or red becauſe he happens to live in another; but the red if his Soil be better, the black if it be worſe.

The Seaſon for felling the Cherry Tree is about the Middle of NOVEMBER; and it is proper to obſerve this punctually, becauſe a great deal of the Value of the Timber depends upon its being cut at a proper Time.

The Woods of the red and black Cherry are very much alike, but that of the black is fineſt, and the Tree is more free to grow ſtrait, tall, and upright. This Timber is not only valuable for its Beauty but its Strength. It will grow to ſuch an Height and Thickneſs in the Trunk, that it will afford good Beams for building; and Experience has ſhewn that they are equal to any Timber, except the Oak, in their Strength and laſting. And it is fit for the Cabinet-maker as well as the Carpenter.

Of all the EUROPEAN Woods there is none that ſo much reſembles Mahogany, as the Timber from the Trunk of a good ſound black Cherry Tree. We are ſenſible that at this Time theſe Trees are rarely rais'd for this Purpoſe; and that what is called Cherry Tree Wood is cut from the red or black Cherry indifferently, and juſt as it happens a Tree has been cut down; but even under theſe Diſadvantages Chairs and Tables are made of it, which have an Appearance of that Wood. It is certain the Reſemblance might be brought much nearer by proper Care.

Mahogany itſelf is not of that beautiful Colour when firſt cut. Time gives it the greateſt Beauty, and when it is freſh wrought into Cabinet-work, they rub it with ſeveral Things to ſtain it. They uſe particularly for this Purpoſe, a red Earth, that is dug in the Iſle of WIGHT: from the Colour it gets by this, and well oiling, it by Degrees becomes of that beautiful Hue we ſo much admire. Now let a Piece of Timber from the ſound Trunk of a black Cherry Tree be wrought in the ſame Manner, be rub'd with the ſame red Earth, and oil'd as the Mahogany is, and I am of Opinion, if not equal, it would be found very nearly equal in Beauty.

Now is it not worth the Planter's while to raiſe a Tree which will be next to the Oak in Strength, and next to the Mahogany in Beauty?

If the Size of the Timber ſhould be objected, it muſt be by thoſe who have not much obſerved the Tree: I have ſeen black Cherry Trees in the Hedges in ſome Parts of HERTFORDSHIRE, of a fine Thickneſs and Height in the Trunk; and when it ſhall become an Article of Huſbandry to raiſe it for the Timber, doubtleſs we ſhall ſee it much larger and finer. There is nothing in Nature to prevent it; moſt of the Form of Trees is owing to the Management of them when young.

The Cherry Tree will grow among other Foreſt Trees in Woods, as well as any Kind, and though it bear little Fruit this Way, it will riſe ſtrait, and

with a tall Trunk; nor is any Tree fitter to be mixed among Coppice Woods, for it grows very freely, and when thus carried up in Height does little Hurt by its Shade. The Boughs are good for Fuel, and it will anſwer many of the other Purpoſes of Coppice.

In fine, the Reaſon why the Cherry Tree has not been ſo much regarded as it ought as a Timber Tree is, that it is underſtood to be of the Fruit Tree Kind: but hereafter, I hope, we ſhall ſee it rais'd on the other Account, in which it is more valuable.

CHAP. XLVI.

Of the Pear Tree.

AFTER the Cherry it may be proper to mention another which is ſo generally looked upon as a Fruit, that it is rarely conſidered as a Timber Tree, although its Wood is, in many Inſtances, ſuperior to any other in the World. This is the Pear Tree, which I hope to remove from the Orchard to the Hedge, and to ſhew the Huſbandman that he has as much Reaſon to value what is called the worſt Kind, as the Gardiner has to prize the beſt.

The Pear Tree, when properly managed, is a large, tall, and well growing Tree. The Bark is rough, the Leaves are roundiſh, and the Flowers reſemble Apple Bloſſoms, but they are whiter. The Fruit is ſufficiently known. It is naturally ſmall, longiſh, and larger at the End fartheſt from the Stalk. Art has brought in a Multitude of Varieties of Taſtes, Colours, and Names of Pears, but the Huſbandman has nothing to do with any of theſe. He is to conſider the Tree for its Timber, and the only Kind that ſhould be planted for that Purpoſe is the common Choak Pear, called in ſome Places the wild Pear: this is the Kind from which all the reſt have been produced by Culture; and is that of which, when leaſt improved, Perry is made. This grows freely in Hedges, and will eaſily be train'd up for Timber.

The Pear Tree will grow in any Soil, and there is ſcarce any in which it will not thrive. It bears a moderate Degree of Moiſture, without any Injury, and only grows the quicker for it; but too much will deſtroy it, and hurt the Timber before any viſible Sign of Decay appears on the Leaves or Branches.

It will grow as well on flat Ground as the Sides of Hills; but does beſt where there is a Depth of Soil. The Pear Tree is beſt rais'd from Seeds. And for this Purpoſe the Huſbandman is to mark a fair and upright Tree, and gather the Fruit juſt when full ripe. A poor Piece of Ground is to be choſen for a Nurſery, and the Trees are to be rais'd and train'd up, as directed for the Cherry. Only taking great Care on the laſt Removal, not to injure the main Root.

The Pear Tree thus rais'd will grow to a conſiderable Height, with a ſtrait and ſingle Trunk, before it begins to bear any Fruit; but when it has once began, the Produce will be yearly very great; and the Fruit, though but poor in Taſte, will yield a great Profit, if made into Perry, which is very eaſily done, as ſhall be ſhewn hereafter; for the Vintners and Wine Coopers are always ready to take it off in any Quantity.

It is ſtrange that this ſingle Circumſtance has not led People more into the propagating this Tree; for the Quantity ſent up to London was never yet enough for the Demand.

While theſe Trees are thus enriching their Owner yearly by their Fruit, they will be all the Time growing up to Timber. A proper Supply of young ones ſhould be planted againſt the Time of felling, that they may yield Fruit for Perry when the others are gone. If theſe Trees are planted in Hedge Rows, forty Foot is a good Diſtance; and four or five Years before the old ones are to be fell'd, there ſhould be brought a Supply of Trees of about ſix Years Growth from the Nurſery, and planted at every forty Foot, as the others, one between each Couple of the old ones.

The old Trees, when fell'd, ſhould be ſtub'd up, and from this Time the young ones will flouriſh and bear ſurprizingly.

The Timber of the Pear Tree is of a delicate fine Grain. It cuts eaſily, and takes a beautiful Poliſh. It is equal to any for the fineſt Works of the Turner; and the Carvers are with Reaſon very fond of it. It is alſo in ſome Places, wrought into Tables, Chairs, and other Furniture. In the Beauty of its Colour, Cloſeneſs and Evenneſs of Grain, and yielding to all Inſtruments in working, it is ſuperior to any Wood whatſoever. There is at preſent a very certain Market for it; but if the Supply were greater the Demand for it would riſe in Proportion, for it would then take the Place of many other the fine Woods.

CHAP. XLVII.

Of the Hazel.

WE now come to the Conſideration of a Tree of ſmall Stature, but being a Fruit Tree it properly follows the others of that Kind, and notwithſtanding its Smallneſs it has ſufficient Value to make it worth the careful Huſbandman's while to look upon it with Regard to Profit.

The Hazel is a low Shrub with broad indented Leaves, and a brown tolerably ſmooth Bark. The Flowers are in a Kind of Catkins. The Fruit is well known, it grows in a different Part of the Tree from the Flowers, and uſually in Cluſters of three or four together.

The Filberd is the Hazel improved and enlarged by Culture; and beſide this we meet with two or three other Kinds among the Nurſerymen. There is firſt, the little white Nut Hazel; ſecondly, the great or Cob-Nut Hazel; thirdly, the red Filberd; fourthly, the white Filberd; and laſtly, the great Spanish Nut, which is angulated on the Surface. Theſe have been only rais'd from the common Hazel, and are not worth the Huſbandman's Regard, he is to ſtick to the natural wild Shrub, leaving theſe to the Nurſerymen and Gardiners.

The Hazel is a ſtout and hardy Shrub, it will grow on the pooreſt Soils, and ſtand in all Expoſures.

poſures. This is a great Article of its Value, for it will ſucceed where many other Trees would altogether fail. It will grow in the toughest or the looſeſt Soils; in Clay, and in Sand; and flouriſhes very well in ſtony Grounds. But the Soil and Situation that ſuit moſt perfectly with it, are a freſh light Earth, on the Side of a Hill, eſpecially if not too ſhallow.

Many propagate the Hazel from Suckers, which they are tempted to do by the great Abundance of them that it produces; and by the Freedom with which they take Root: but the beſt Method is from Seed, and this is ſo eaſy, that 'tis not worth while to take any other.

To this Purpoſe let the Huſbandman gather a good Quantity of Nuts when they are thoroughly ripe, from the moſt flouriſhing Trees. Let a Bed of Sand be ſpread upon the Floor of ſome cool Room, and theſe Nuts laid on it, covering them with a little more dry Sand; and thus they are to lie the whole Winter. In FEBRUARY they are to be ſown in Trenches, in a poor Ground, and tranſplanted when they are of two Years Growth. They are to ſtand a Couple of Years in their new Place, and then to be removed to the Hedge Rows, or elſewhere, where they are to remain.

When a Coppice is raiſed from Seed, the Nuts may be ſown among the reſt, but it may be thicken'd afterwards by tranſplanting more of them into it.

The Nurſerymen and Gardiners propagate their Filberds by Layers; but though this may be the beſt Way, when they are raiſed for the Sake of the Fruit; the ſowing them is beſt for other Purpoſes.

After they are removed to the Places where they are to ſtand, they muſt be cut down within five Inches of the Ground: if they are pretty large when they are removed, this may be done the firſt Year; but if ſmaller, it is better let alone till the ſecond.

When they are planted in Coppices, they are fit to fell with the reſt of the Growth, at twelve or thirteen Years old; and, after the firſt cutting, they may ſtand ſeven or eight Years.

No Shrub anſwers better for the thickening of a Coppice, by laying down a Branch, than the Hazel. One long Pole chop'd half through near the Ground, and cover'd for its whole Length five or ſix Inches deep with Earth, faſtening it down with a Peg, will yield a Row of fine Shoots.

The Hazel, when cut at ten or twelve Years Growth, yields a very good Price. It is eſteemed by the Hoop-makers, and on many other Occaſions; and, in ſome Parts of ENGLAND, is raiſed ſingly in very large Plantations for this Service. Its Fruit are a very great Diſadvantage, for they occaſion its being broke and torn to pieces by Boys, before it is in a Condition to cut; and this is a great Reaſon againſt planting the Hazel in Hedge Rows, where elſe it would thrive very well and grow to uſe. Not that it is by any Means a good Shrub for the ſerviceable Parts of a Hedge, for it does not grow cloſe, nor does it bear plaiſhing: it alſo wants Thorns for the Purpoſe of keeping off Cattle.

'Tis beſt to raiſe it ſingly in Plantations for the Hoop-makets, or among Coppice Wood. Beſide the Hoop-maker, it is uſed by the Thatcher, for the making of Hurdles, and on many other ſuch Occaſions. Its fine taper Shoots are uſed for fiſhing Rods, and the worſt of it is very good for faggoting.

The ſmall Branches of the Hazel burn to a fine light Kind of Charcoal, and are, in ſome Places, uſed for the making Gun Powder. The Chips of Hazel Wood are alſo uſed by the Wine Coopers, and are a very harmleſs Ingredient for the fining of Wines.

CHAP. XLVIII.

Of the Buckthorn.

FROM the Hazel we ſhall advance to another Shrub, whoſe Fruit is of Value; the Buckthorn. It is indeed of ſo much Value, that one is ſurprized the Huſbandman ſhould not think it worth his while to give the Shrub a Place in his Hedges; for it will, in a tolerable Soil, grow as freely there as any other Kind; and anſwer the Purpoſe of fencing better than many that are conſtantly planted there merely from Cuſtom, and without any particular Reaſon, or any tolerable Uſe.

The Buckthorn is a Shrub of ten or twelve Foot high, the Bark is brown and ſmooth, the Leaves are oblong, and the Flowers are ſmall. The Fruit is a Berry, roundiſh, black when ripe, and juicy, containing four hard Seeds, which are rounded on one Side, and flatted on the other.

This Deſcription of the Berry admits of no Miſtake in the Shrub, for if any one ſhould at random think to raiſe it from Berries bought at the Markets, he might be ſtrangely diſappointed; as the People who gather it frequently, though very diſhoneſtly, bring the Berries of the black Alder, and ſome other Shrubs among them: the Berries of the black Alder moſt reſemble them, but there are only two Seeds in each of theſe.

The Buckthorn Shrub loves a light and rich Soil. We ſee it in Hedges on other Kinds of Ground, but it does not flouriſh when it has not free Room to ſpread its Roots, and Plenty of Nouriſhment. For Situation, a Flat toward the Bottom of a Hill is the beſt; but there is no need to be very ſtrict in theſe Things: it may be planted among the Quick of a Hedge any where; only if there be Choice of Soils and Situations, it will bear its Fruit more plentifully and conſtantly, and it will ripen it better on theſe juſt named than on others.

Buckthorn is to be propagated by ſowing. And for this Purpoſe the Berries ſhould be gather'd from a thriving Tree late in Autumn, when they are thorough ripe; and ſown immediately in ſhallow Trenches, in a Bed of a loamy and light Soil.

When the young Trees firſt appear, they ſhould be water'd a little, if the Seaſon be dry, and kept clear of Weeds; after this they ſhould be treated exactly in the Manner of the Sloe or black Thorn Plant, as deſcribed already in their

Place; and planted with the Quick on the Bank in making of the Hedge; where they will grow up with the reſt. One Plant of Buckthorn may be ſet at every fifteenth of Quick, and the Hedge will not be at all the worſe for it.

The Stem of the Buckthorn will grow to the common Bigneſs of the Hedge Wood, and when cut in the plaiſhing and new making the Hedge, will anſwer the uſual Purpoſes, and in the mean time every Year there will be a great Quantity of the Berries which ſell at a very conſiderable Price. The Apothecaries buy them to make a purging Syrup, which has its Name from the Shrub.

CHAP. XLIX.

Of the Alder.

THE Alder has been occaſionally mentioned in the preceeding Book, as uſeful for defending a mellow Shore from being undermin'd by the Stream of a River: but we are here to enquire more at large into its Nature, and after that, ſhall ſpeak of ſeveral other of thoſe Trees that grow in wet Places.

I have mention'd in the laſt Chapter, a Shrub called the black Alder, whoſe Berries are often mix'd among thoſe of Buckthorn at the Markets: but that is a little Shrub no way allied to the right Alder, except in the Shape of the Leaf, from whence careleſs People, not regarding the more eſſential Characters of either, called it by the ſame Name.

The Alder properly ſo called, is as commonly rais'd a very large Shrub, conſiſting of a great Number of tall and thick Shoots riſing from one common Stump; but it may be rais'd ſingly, and in Form of a Tree; and will acquire a very conſiderable Bigneſs. The Bark is ſmooth, and of a dark purpliſh brown Colour; the Leaves are large and roundiſh, and uſually feel clammy: the Flower is in a Catkin in the Manner of the Hazel; and the Fruit is a ſmall light Cone produced on a different Part of the Tree, and ſeldom much regarded.

The proper Soil for the Alder is a rich black Mould; and its proper Situation is in a Flat, near the Edge of ſome little River: it thrives particularly in half boggy Places, where the Water every now and then floats the Ground, and lies ſome time upon it. The little Rivers of BUCKINGHAMSHIRE and HERTFORDSHIRE, that run through rich Meadows, have a large Quantity of fine Alders upon their Banks; and whereever they overflow frequently, the ſame Trees riſe from the Spreadings of the Roots of the adjoining ones in great Abundance.

The great Benefit of this Tree to the Farmer is, that it will live and thrive in ſuch Places as will not agree with any other Kinds; and if ſuch Grounds were univerſally planted with it, it would be of great Benefit to the Owners, as there is a conſtant Demand for the Timber, though at a ſmall Price.

The Propagation of the Alder is extreamly eaſy, for the raiſing it in the uſual Manner in Clumps of Poles; but a little more Care is requir'd in propagating it for a Tree, and 'tis very well worth while to take it.

The Alder will riſe from ſowing the little Cone or Fruit, but this is a tedious Way. The common Method is to cut the Poles into Truncheons of a Yard long, and ſet theſe in the Ground in a rich wet Earth. They will grow as readily as the Willow or Elder; and thus naturally ſend up a great many Shoots, which is the common Intention in the planting them.

The Truncheons are to be planted in the Beginning of APRIL. Some cut them immediately for that Purpoſe; others cut them in OCTOBER, and tying them in Bundles, leave them with the larger End in Water all Winter, and then plant them in Spring. This they do to make ſure of their growing, but it is an unneceſſary Trouble: they generally ſtrike Root very freely; and if there be any Doubt, 'tis but planting ſome ſpare ones, and thoſe which do not take may be pulled up.

Another Method is to plant a Piece of the Root of an Alder deep in the Mud croſswiſe, that a Tree may riſe from it, and this deep laying in of the Root ſecures it from Injury by Winds. Others bury a long Pole of Alder, cutting off both Ends, and it will ſhoot up many Branches, which are to be cut off near the Ground, and then left to ſhoot afreſh in Numbers from each Place where they were cut.

But though all theſe Methods are not only recommended, and frequently uſed with Succeſs, I ſhall adviſe a Huſbandman to a Courſe quite different from them all; which is, to raiſe the Alder from Layers, in the Manner as deſcribed under the Article Elm: for no Tree whatſoever takes in this Method more freely. The Shoots taking Root immediately, and bearing tranſplanting excellently.

The Nurſery for this Purpoſe muſt be in ſome wet Place by a River Side, where a few Stools of Alder will afford a continual Supply. At a Year after the laying, the Shoots are to be taken off and tranſplanted. To this Purpoſe let there be a Number of Holes dug at ſeven Foot Diſtance every Way to receive them. Theſe Holes muſt be two Foot deep: the young Trees muſt be taken up carefully, and planted at leaſt a Foot and half deep upon ſome looſe Mould in the Bottom of the Hole, and the Earth well put in about them. Every Shoot will thus grow, and no Method is ſo certain or ſo advantageous.

One Year after they are planted let the Owner go over them, and take Notice which are the fineſt, ſtrongeſt and ſtraiteſt Shoots; theſe are to remain as they ſtand, but the weaker he is to cut down within about ſix Inches of the Ground. The Number to be left for Trees ſhould be nearly half, and the others will ſhoot up from the cutting in long and ſtrait Poles in the uſual Way. Thus he will have a Parcel of Alders riſing up to Trees, ſo far as their Nature will bear, and another Parcel of the uſual Kind, which are to be felled as common Alders, while the others remain like the Timber Trees in a Coppice, increaſing

in Bigneſs and Value, and ſtanding throughout ſeveral Cuttings of the ſmaller.

Alders growing in the common Way, are to be cut once in four Years. For they are a very quick growing Tree; the Wood being light, and there being Plenty of Moiſture for it, which is the great Support of all Growths.

The Bark of the Alder was at one Time in Uſe among the Dyers for black, but at preſent it is little regarded. While it was uſed to this Purpoſe, the Time of felling the Alder was in Spring, becauſe the Bark then came off eaſy. At preſent 'tis felled in NOVEMBER and DECEMBER, and the Wood is found of a greater Firmneſs than it uſed to be when cut in the Sap Seaſon.

It is, however, proper to bark the larger and better Pieces of the Alder whereſoever they are cut, tho' the Bark be not uſed for any Thing; for there are apt to breed Worms under the Bark which deſtroy the Timber, but it is ſeldom hurt by them when the Bark is off.

No Tree grows quicker than the Alder, nor does any of the ſoft Wood Kinds make a better Return in Profit; 'tis therefore a Wonder it ſhould be any where neglected where there is Ground that is fit for it. The Farmer always finds Purchaſers at a better Price for his old over-grown Alders, as they are called: therefore why will he not raiſe a Quantity of good Trees to ſuch a Size.

The Uſes of the Alder are many. The ſmaller Poles make Hurdles and Gates as well as any Wood whatſoever; and of the larger Pieces, Chairs, Country Utenſils of many Kinds, and Clogs and Shoe Heels are made, and a great Number of other Things that require a light and yet firm Wood.

It bears to lie wet as well as any Wood whatſoever, but then it muſt be always in Water, for if it be ſometimes dry and at other Times wet, it periſhes quickly. We read in the old LATIN Authors, that the Alder was made the Foundation of Bridges, and other Buildings in boggy Grounds: and it ſtands upon Record that there is a great deal of Alder uſed under our old Bridge at LONDON, and under the Rialto at VENICE.

There are thoſe who ſay Alder hardens by Degrees under Water, till it becomes a Kind of Stone, but this is falſe. It is ſufficient that it will laſt a vaſt while on theſe Occaſions; and it is plain from hence, that if a Supply of large Alder could be had for ſuch Works as are to remain under Water, there would be a ſufficient Demand for it: and this may be done on the Methods here laid down.

The Alder ſerves excellently for Piles of all Kinds, driven under Water; and Faggots of this Wood are excellent for laying in Trenches, cut through boggy Grounds to prevent their filling up. The Poles ſell well to the Hop Planters, and the ſmall Branches make an excellent Charcoal for Gun Powder.

The great Conſumption of the large and ſound Timber would be among the Turners. It is a very firm and light Wood, ſo that the Bowls, Diſhes, and the like made from it, would be preferable in that Reſpect to thoſe of Beech, and ſmoother and handſomer than thoſe of Elm, which are always harſh and ragged.

There is a Toughneſs in ſound Alder that will make it bear turning very thin; and it is worth the Conſideration of the Carver; anſwering freely to his Chiſſel, and yet holding together in very fine and ſmall Work.

A Plantation of Alder, beſide the Eaſe with which it is made; and its Readineſs to flouriſh where other Trees will not grow, has this Advantage, that the Leaves and young Shoots are ſo ill taſted, no Creature will crop them. So that it needs no Trouble or Expence in fencing.

I have named all theſe Advantages of the Alder, that more may be tempted to plant it than do at preſent. I have ſeen many a large Piece of Ground left waſte, on which Alders would thrive perfectly well; and which would by ſuch planting bring a vaſt Profit to the Owner.

CHAP. L.

Of the Willow.

THE Willow is another of the watery Trees, which, although frequent enough in ſome Places, is not nearly ſo much cultivated as it might be; and which, under a better Management than is generally beſtow'd upon it at preſent, would yield very great Advantages to the Owner.

The Willow, when the right Kind is choſen, and right Management is given it, grows to a conſiderably large and tall Tree. The Bark is pale colour'd, rough and cracked; the Wood light and whitiſh: the Leaves are long and narrow. The Flowers are ſmall, thready, and form'd into a Kind of Spike: the Fruit grows on other Trees of the ſame Kind, and contains a downy Seed.

There are ſeveral Kinds of Willow; but few of them are worth the Huſbandman's Notice, or Conſideration: the Ozier and the Sallow are properly of the Willow Kind, but theſe differing from the common Willow in many Reſpects, ſhall be treated of in ſeparate Chapters hereafter. Among the other Kinds the common tall Willow, or white Willow, which freely and naturally riſes into a Tree, and which the Farmers in ſome Places diſtinguiſh by the Name of the withy, is the principal in Value. Next to this is the large leav'd green Willow, which is generally kept a Pollard. And the others being all inferior to theſe two in Growth and Value of the Wood, are to be neglected.

The proper and natural Soil of the Willow is a damp rich Earth: near Waters, and in flat Grounds, is its favourite Situation. Of the two Kinds juſt mention'd, the white leav'd Willow, which naturally grows into a Tree, will do with leaſt Moiſture: the other, or green leav'd Kind, which is beſt kept for ſhrowding, loves the wetteſt Places. Let the Farmer keep this in his Remembrance always: for on theſe careful Diſtinctions, and the exact ſuiting of the Soil to the Kind of Tree, depends in a very great

Degree,

Degree, the Advantage of one Perſon over another in his Plantations.

The Willow, of which ever Kind it is, is a Tree very eaſily propagated; for it will take Root in any Form, and under any Manner of planting whatſoever; and will thrive wherever there is Water. The white Willow will do even where there is but a moderate Quantity of Moiſture. It will thrive in clayey and loamy Soils, and will often riſe to a conſiderable Stature in Hedges, and on waſte Grounds, that are very far from any Water.

The common Way of propagating the Willow of either Kind is by cutting Poles of ten Foot long: theſe are to be ſtruck off one Way at the Bottom, and thruſt two Foot and a half deep into the Ground in moiſt Places. This is ſo eaſy and expeditious a Method, that few will ever be led to think of practiſing any other: and indeed none is better for the green Willow, which is intended for a Pollard, becauſe a little Advance in Height gives it the proper Length of Trunk, and the Shrowds naturally grow from the Top. But for raiſing Trees of the white Willow, or Withy, I altogether prefer the Method by Layers. Theſe are procured with the greateſt Eaſe, in the Manner directed under the Article Elm, only chuſing a wet Piece of Ground for the Stools; and being afterwards planted in deep Holes, as directed for the Alder, they take firm Root, and grow up with a ſurprizing Quickneſs. When theſe Trees ſtand on a moderately dry Soil, they quickly riſe to a ſound and good Timber, conſiſting of a large Blea, and a rediſh Heart, which is firm and beautiful, and bears a tolerable Price.

The beſt Time of planting the Willow is toward the End of FEBRUARY: and if the common Method by Poles or Truncheons be uſed, it will be proper to let them ſtand with the End in Water, that is to be thruſt into the Ground four or five Days before they are planted. The Diſtance ſhould be about fifteen Foot, and Care ſhould be taken not to rub up the Bark in thruſting the Stake into the Ground. The Careleſsneſs of the Planter in this Reſpect, has often prevented the Willows taking good Root, and this has been laid to the Charge of the Soil.

The common green Willow in the Pollard Form, is of ſo quick Growth in the Branches, that it may be cut once in four Years. The Seaſon for this is NOVEMBER or FEBRUARY, and one is as well as the other. But as this Tree is of ſuch ſpeedy Growth, it is alſo of quick Decay, and this is to be provided againſt.

A Plantation of Pollard Willows ſhould never be expected to ſtand longer than five and twenty Years; ſo that a freſh Supply ſhould be raiſed againſt that Time, by planting new Stakes or Truncheons between; and the old ones ſhould then be grub'd up while their Trunk is ſound; for ſoon after that Time, and often before, from Damages and Accidents, it grows hollow, and moulders away into a Kind of Touch-wood.

The Miſchief commonly begins at the Top, where the Wet gets in after cutting off the Shrowds, and ſo penetrates all the Way down.

The Pollard Trees of this Kind muſt be carried to a Height above the Reach of Cattle, before they are ſuffer'd to ſhoot for a Head, for they are very fond of cropping the young Shoots of this, though none of them will touch the Alder.

When the white Willow, or as ſome call it, the red Willow, from the Redneſs of its Heart, is to be raiſed for a Tree, the uſual Care is to be taken in trimming it up, to let no large Side Branches ſhoot; and to leave a few ſmall ones to call up and detain the Sap in the Trunk: by this Means it will riſe to a tall and well looking Tree.

This Kind, as well as the other, may be cut for ſhrowding, and either of them are of great Uſe this Way in Places where Fuel is ſcarce, for they yield a very great Quantity, and a quick Return. A Perſon who has but a moderate Number of them, by allotting them into four Diviſions, and cutting one Part every Year, may have an annual Supply.

The Willow is of great Uſe alſo in Hedges in proper Soils. The Stakes being made of this Wood, will all grow, and at once continue firm, and thicken the Hedge.

The Wood anſwers many of the Purpoſes of the Alder, and many others; the Poles make Hurdles and Fences, and Withs for the tying up of Faggots. They are uſed by the Thatchers inſtead of Hazel; and they burn into an excellent light Charcoal. For Quantity it has been computed, that an Acre of Ground properly planted with Willow, will at eleven Years Growth yield a Hundred Load of Wood. The large Wood is uſed by the Turners, and when good, brings a conſiderable Price. The worſt of it may be ſplit out into billetting, and burns excellently.

When the Willow is raiſed in a Tree, and has a long and ſound Trunk, it may be cut into Boards, and uſed in Building, for they are ſtrong, of a good Grain, and very beautiful.

CHAP. LI.

Of the Ozier.

THE Ozier is a ſmall Kind of Willow; which from the particular Uſes for which it is raiſed, requires a different Sort of Management, and another Manner of planting.

The Ozier very much reſembles the Willow in its Appearance, but that is a ſmaller Tree, its Shoots are longer and ſlenderer, and its Leaves alſo much longer, theſe are very narrow, and in the beſt Kind are green on the upper Side, but whitiſh, and as it were, woolly underneath.

The Ozier loves a wet and low Ground, near Waters, and nearly upon a Level with the Water. It thrives no where ſo well as in marſhy Places, near the Edges of large Rivers; or in thoſe little Iſlands that are form'd by the breaking of their Current; and every Way ſurrounded by the Water. The Ground for an Ozier Bed ſhould be a rich black Mould; and this is very common in theſe low and wet Situations.

The Deſign in planting the Ozier is, that it may ſhoot out a great Quantity of fine ſlender Twigs,

Twigs, which are to be cut at a ſmall Growth. Therefore there is no Occaſion for a Trunk either of the Pollard or Timber Tree Form. This would only exhauſt a great deal of the Nouriſhment taken in by the Root, and deprive the Shoots of it; neither are they ſo apt to riſe ſtrait and fine, unleſs they begin near the Ground.

On this depends the peculiar Way of planting the Ozier. It is rais'd in the ſame Manner as the other Willows, by Truncheons or Stakes driven into the Ground; and it is proper always to let a certain Quantity of the Shoots ſtand for a due Growth for this Purpoſe, when the reſt are cut. But as theſe are not to riſe in a Trunk, they muſt not be above four Foot in length, and three Foot of this muſt be thruſt into the Ground.

They will, by this Means, have a fine Supply of Roots; and beginning to ſhoot ſo near the Earth, all the Nouriſhment will be carried up into the Twigs.

Theſe Stakes are to be planted at three Foot diſtance, and they will quickly yield a large Profit: the Twigs riſe numerous from their Tops; and being cut down pretty cloſe, in the Manner of ſhrowding Pollard Trees, they ſend up a new Set of Twigs again almoſt immediately, which quickly grow to their proper Size.

The Time of cutting Oziers is in SEPTEMBER; and the Advantage that may be made of planting them is very great. Many waſte Pieces of wet Ground might be made to yield a great Profit by them.

If Stakes or Truncheons of a proper Bigneſs cannot be had, more Time will be requir'd to raiſe the Ozier Bed; but it may be done from ſmaller Sets. Theſe are to be cut four or five Foot long, and ſtuck at the ſame Diſtances into the Ground. They will grow very freely; and when they have ſtood three Years they are to be cut down, within a Foot of the Ground; and from thence will riſe the Twigs in great Abundance; and they will continue affording a Supply of them many Years.

The fineſt and beſt Kind of Ozier is that I have deſcribed with long Leaves, white underneath; but there are ſeveral others that anſwer the Purpoſe very well. The Twigs are of conſtant and ready Sale. The Baſket-maker's Work depends upon them; and there is a great Conſumption of them among the Fiſhermen. The Wheels, as they are called, for catching Eels and other Fiſh, are made of them: and Baſkets, Hampers, and the like, of which the Conſumption is, in a Manner, endleſs and unlimited.

The quick Growth of the Twigs is a great Article in the Profit of an Ozier Holt, for they are cut every Year; and the Heads that bear them grow for a long Time more and more buſhy at every cutting. So that here is a vaſt Profit to be made with ſcarce any Expence; annually returned and increaſed every Year; and this upon Ground fit for nothing elſe; for the Ozier will grow and flouriſh on Ground that is ſo looſe and ſo wet, that it would not afford Hold for the Root of any other Kind of Plantation whatſoever.

As the Stems of the Ozier will decay in Time, let the Huſbandman always take Care to have a Supply. Nothing is ſo eaſy: for 'tis only ſticking into the Ground ſome Twigs between the Stems, which will take their Time to root themſelves, and grow to a due Bigneſs; and when properly cut, and managed according to the Directions already given, of raiſing an Oſier Ground from Sets, will be ready to yield their Produce as the old ones begin to decay; and may thus be made to ſupply their Place gradually as they are wanted.

CHAP. LII.

Of the Sallow.

THE Sallow is alſo properly a Kind of Willow, but ſo far different in its Cultivation and Uſe, that it very properly falls under Conſideration in a diſtinct Chapter.

There are ſeveral Kinds of Sallow, as there are of Ozier; and all of them anſwer the ſame Purpoſes, in a more or leſs perfect Degree: but as I have mentioned which is the beſt Ozier, I ſhall, in the ſame Manner, acquaint the Huſbandman that the Kind of Sallow which will beſt anſwer his Care in raiſing, is that which has a roundiſh Leaf, of a pale whitiſh green Colour, and rough. This is common in Hedges, and it is from this he will do beſt to raiſe his Stock.

The proper Soil of the Sallow is a rich black Earth, where there is a tolerable Degree of Moiſture; and its moſt favourable Situation is in the damp Part of a Coppice, or in a Hedge Row in a flat Meadow, where there is a wet Ditch at the Bottom.

It is in theſe Places the Sallow riſes to its greateſt Perfection, but it is not confin'd to theſe, for it will grow in loamy or clayey Soils far from Water, and in almoſt any Situation.

The Advantage of planting the Sallow in its beſt and moſt favourable Soil is, that it grows very quick. It is an excellent Shrub to mix with white Thorn in Hedges, and in this Caſe it will be fit for cutting every four Years; ſo that it yields double the Wood of any other Kind in a Fence; and at the ſame Time improves and ſtrengthens it in every Reſpect.

The Sallow may be propagated in the ſame Manner as the Willow and Ozier, by ſticking Stakes or Truncheons of it into the Ground, which will grow without farther Trouble: but when it is ſet in a Hedge, the beſt Method is to plant the Sets with the white Thorn, and let them grow up together.

The Sets of Sallow may be planted on the oppoſite Side of the Bank from the white Thorn, of the Hedge; becauſe they will be fit to cut before the white Thorn is half grown.

If Sets are not in readineſs rais'd in the Manner of the white Thorn; Pieces of Sallow Twigs of a Yard long, and an Inch thick, may be let into the Bank ſlope-wiſe, at proper Diſtances; and they will grow very well. The beſt Method is to make an Hole with an Iron Crow, for if the Sallow Stake be thruſt in of itſelf, the Bark is often injured, and it will not grow.

Chalk and Sand are the only Soils on which the Sallow will not thrive. A loamy Earth in the Neighbourhood of Water, will make it puſh at a great Rate: faſter indeed than in pure Mould, becauſe

becauſe of the Warmth there is in the Sand, that is in this Kind of Soil, and the free Paſſage of the Water; but I have found by Experience, that the Wood is firmer and better when it grows on a good Mould.

The beſt Time for cutting the Sallow is early in Spring; for it then ſhoots out almoſt inſtantly on the cutting: and I am to adviſe the Huſbandman to uſe ſome Care and Caution in the Manner of doing it. It is a common Complaint that Sallow Stumps are not laſting: if this were true the Objection would not be of any great Force, they are ſo eaſily ſupplied; but it is the careleſs or ignorant Manner of cutting, that makes them decay. If the Shoots are ill cut, their Ends left long and ſtraggling, and haggled by a clumſy Workman, they will let in wet and decay the Stumps: but let them be cut off cloſe and ſmooth, and at a proper Seaſon, and the Sallow ſhall laſt as long as the Thorn.

The Quantity of Wood produced by the Sallow is of great Advantage to the Farmer, becauſe he always has it ready to make up, thicken and mend his Fences. The Poles of the Sallow are uſed to make Hurdles, and when they are larger they turn to yet better Account in making Rails, Rafters, and the like.

I have propoſed to the Huſbandman to raiſe the Alder into a Timber Tree, inſtead of letting it riſe in Poles, as is the Cuſtom; and the ſame Thing may be done with the Sallow.

Though we uſually ſee it as a low Shrub, it may be rais'd from Layers, in the Manner already directed for the Alder, and train'd up into a regular well-bodied Tree. In the damp Parts of the Woods it will grow among the other Timber. And Plants of it thus rais'd, may be left Standards in the felling of Coppices, while thoſe that grow in the uſual Way are cut with the reſt.

The Sallow, thus rais'd to a Tree, affords a firm and very tough Wood, that ſplits eaſily with the Grain, and may be uſed on a great many Occaſions in Country Building.

The Heart of the Sallow, when thus rais'd into a Tree, is red, like that of the Willow, and it is very firm: 'tis ſaid, that if kept dry it will laſt as long as the Oak; and I have ſeen Trees from which very large Beams of it might have been cut, ſome of them being fifty Foot high, and of a good Thickneſs.

No Shrub requires more Care to defend it from Cattle than the Sallow, in the common Way of raiſing it. For the young Shoots and Tops of the Branches are very ſweet, and they are very fond of them. The Value of the Wood, in this Way, conſiſts in the Length and Straitneſs of the Poles, which will often grow to ten or twelve Foot: they will naturally grow to this if uninjur'd, but the Cattles biting off the Tops makes them commonly grow buſhy, ſhort, and irregular.

It is beſt for the Stem, as before obſerved, to cut the Sallow Poles in Spring, but it is for the Advantage of the Wood to cut it in Winter, while the Sap is down. Therefore when the Poles are large, and likely to bring a Price from the Turner and Joiner, it is beſt to cut them in November; but when they are ſmall, and deſign'd for Fire Wood, or repairing of Fences, it is beſt to do it in Spring.

One great Advantage the Sallow has over moſt of the other Shrubs, whether in an Hedge or Coppice, which is, the Eaſe wherewith it thickens them in Places where there are Vacancies by laying down. A Pole of Sallow of ten Foot long, may be brought to the Ground by a Chop almoſt through, at the Bottom, and laid in a ſmall Trench opened for that Purpoſe; in this let it be peg'd down, and cover'd with Mould; and there will riſe a little Foreſt of Sallows from it; as many of which may be ſuffered to grow as are needful to the Occaſion.

In moſt Places where there are Sallows, the Ground ſeems to produce young Trees of the ſame Kind, as it were of itſelf, often at a conſiderable Diſtance from the old ones. Theſe riſe from the Seed; they may be taken up, and train'd to goodly Trees: but the Method by Layers is equally certain of Succeſs, and is proceeding with little Trouble and great Regularity.

CHAP. LIII.

Of the Fir Tree.

THE Fir is a Tree not native of this Country, but which may be propagated here with Advantage. Its many and great Uſes are ſufficiently known; and every Huſbandman muſt wiſh that he had it in his Power to raiſe it. How far that may be done profitably ſhall be ſhewn.

The Fir Tree is an ever-green; tall, ſtately, and of an extreamly regular and beautiful Growth. The Bark is of a pale rediſh brown, rough and crack'd in many Places: the Leaves are ſmall, ſlender, and grow in vaſt Abundance on every Part of the ſmall Branches: the Flower is a Kind of Catkin, and the Fruit grows on a different Part of the Tree. It is oblong, hard, and ſcaly, and is called a Fir Cone, and by the Vulgar a Pine Apple.

There are ſeveral Kinds of Fir in the Counties where that Tree is a Native; and a great many of them have been brought into our curious Gardens: but the Huſbandman who would plant Firs with a View to Advantage, muſt make Choice of that Kind which is called the Norway Fir, or Spruce Fir, which is the Sort that affords the fine Deals we have from that Country. This is called by Authors the common Fir, or the Pitch Tree; and is diſtinguiſhed from the others by the Smallneſs of the Leaf, and by the Fruit hanging down.

There are two or three other very hardy Kinds which have been long cultivated in ſome Parts of England, and may be worth his Notice, but the Kind juſt mentioned is the Standard and principal Sort.

The firſt of theſe others is that called the Cornish Fir. The Leaves of this grow like thoſe of the Yew Tree, and the Fruit is very long and hangs down. This was originally an American Tree, but ſome of them are planted, many Years ſince, in Devonshire, which ſtill live and thrive there exceedingly.

Two others are the ſmall con'd Fir, and the

the ſhort leav'd Fir, both theſe came over alſo from AMERICA, but there are many Trees of them in DEVONSHIRE and CORNWALL, where they were long ſince planted, and where they ſtand, and have grown to a great Size. There are alſo ſome other Kinds that will bear our Climate very well: but as the firſt named Species is the moſt immediately to the Planter's Purpoſe, it is that he is principally to have in View.

As to the others, he may do well to mix ſome of them among his Plantations of that Species, to ſee the different Succeſs, as this Kind of planting is but new yet in ENGLAND, with a View to Uſe. Perhaps in ſome Places one of the AMERICAN Firs may ſucceed where the NORWAY Kind would not; in that Caſe it will be right to raiſe ſuch, and try their Value at the Market.

The beſt Soil for Fir Trees is a barren, poor, ſtony, or gravelly Land, where there is Clay at the Bottom; and their moſt favourable Situation is on the Tops and Sides of Hills. This alone would be a very ſufficient Reaſon for the Huſbandman's undertaking to cultivate them in ENGLAND, becauſe there is a great deal of ſuch Ground that is waſte with us, for want of proper Growths. Though we hope one good Conſequence of this Work, will be the remedying that Evil, becauſe there are propoſed in it valuable Kinds for every Soil and Situation in the Kingdom; ſo that no Inch of Land need be left waſte, except by the Careleſsneſs of the Owner.

But though a ſtony Soil with a Clay Bottom be the beſt for the Fir Tree, it is not the only Kind in which they will thrive. Firs of vaſt Bulk grow both in NORWAY and in NORTH AMERICA, on cold Clay, and many other Soils, as well as in lower Situations: on chalky Hills alſo it thrives excellently. This Tree does not ſucceed in very looſe or light ſandy Soils, nor in the rich mellow Earth, where there is little or no Admixture, but in almoſt any other it will thrive more or leſs, and yield a large Profit to the Planter.

There are ſeveral Plantations of them in different Counties, where they grow well on different Soils; but by Obſervation, and examining the Ground, I have conſtantly found that they ſucceed the beſt where there is a Clay at the Bottom; and where they ſtand expos'd as open upon hilly Grounds or Commons.

Nature produces a great Part of the Firs on cold rocky Mountains: we ſee by thoſe Examples already cited, that it is a Tree which will grow in this Country: we have enough of theſe rocky and bleak Hills of little Value in the Kingdom; what therefore can be ſo reaſonable as to try whether this Tree may not be planted upon them to Advantage.

The Fir Tree is to be raiſed from Seeds, and as this requires a different Management from the rearing any of our own Trees, I ſhall, for the perfect Information of the Huſbandman, here ſet it down at large.

Let the Fruit, or Cones, be gather'd when perfectly ripe, from a large and well growing Tree: and ſpread upon the Floor of a dry airy Room. There let them lie all Winter.

In the firſt Week of MARCH prepare the Ground by plowing two or three Times, which will improve the Soil, and thoroughly deſtroy the Roots of all pernicious Weeds.

When this is done, let a ſmall Spot of two Foot wide be better broke and levelled with a Spade at every ten Foot Diſtance; and while this is doing, let the Seeds be got out of the Fruit, or Cones, that have lain the Winter drying. This is to be done by ſoaking them, they are to be thrown into a large Tub of River Water over Night, and taken out in the Morning; at which Time the ſeveral Cells they contain will readily open, and the Seeds may be taken out.

On each Spot of the Earth levelled and prepared by the Spade, let there be ſown half a Dozen good Seeds. Let them be cover'd about an Inch with Mould; and let a little Piece of a Furze, or black Thorn Buſh, be laid over them by way of Defence. This will keep the Birds off; and will alſo make the Ground a little moiſt, which will promote their ſhooting.

When the young Trees appear, the Furze Buſh is to be taken off, and that and two or three others ſtuck in the Ground round about each Spot; this will ſerve to keep off the Sun and Winds, as well as other Enemies to young Plantations.

Three or four Plants will naturally riſe in each Spot. When they are at a little Height, the Earth ſhould be drawn up about the Stem, and thus they are to remain three Years, laying ſome looſe Stuff of any Kind about them, to keep the Ground moiſt and warm.

At three Years Growth all the Plants of each Spot are to be taken up, except one: the faireſt and ſtrongeſt is to be left, and great Care is to be had not to diſturb its Roots in raiſing up the others, and to ſettle the Earth about it when they are gone.

Thoſe which are taken up may be planted out in other Ground; and the ſingle vigorous and thriving ones left in their proper Places, will then grow up apace into a beautiful Plantation. Their Nearneſs will naturally prevent their ſpreading into a great Quantity of Side Branches; they will run up in Height, and with a little Care, form a very beautiful Plantation of Evergreens: a great Ornament to the Place.

A little Litter ſhould be ſtrew'd about the Roots, which will keep the Ground moiſt, and anſwer the Purpoſe of watering. If any Water be neceſſary, it muſt be given in ſmall Quantities, eſpecially to thoſe Trees which are tranſplanted: for many have been deſtroy'd by it, Practice when too much is given.

In this Manner a Plantation of Firs may be raiſed with great Eaſe, and it will flouriſh without any farther Care, on chalky or ſtony Soils; and on clayey ones that are not too wet; and beſt of all upon thoſe Hills where the Huſbandman finds it moſt difficult to make any uſeful Growth thrive.

They will be a vaſt Beauty to the Country; and the Profits ariſing from them when they are well underſtood, cannot fail to be very great.

They ſeem ſlow in their Growth while young:

but

but let not that diſhearten the Planter; for it is only during a few of the firſt Years. After the firſt ſix or ſeven Seaſons they ſhoot up at a great Rate; and increaſe in Bulk in Proportion. Fir Trees in ENGLAND have riſen to ſixty Foot Height, and a proportionable Bulk of Body in twenty Years. At about thirty Years they will be fit for felling for all the common Uſes of Building, and if the faireſt and ſtatelieſt Trees be ſuffer'd to ſtand ten or twelve Years longer, they will be fit for the Service of the Navy, or any other Offices that require the large and fine Deals.

Of all Parts of the Kingdom one would moſt wiſh to ſee theſe Plantations made about the Coaſts, where the Demand would be always great for the Timber; but in every Place Deal is ſo uſeful a Wood, that it could never want a Market. It is unqueſtionable but that we might raiſe theſe Trees ſo as to ſupply Maſts to our Veſſels, and every other Purpoſe for which ſo much of this Timber is annually imported at ſo large a Price, and which grows upon juſt ſuch Hills as we all the Time leave deſolate and uncultivated.

Deal is in a Manner an univerſal Wood in Building. Our Wainſcots, Floors, and other Parts of the Houſe are made of it; it is very laſting when kept dry, and 'tis no little Advantage to the Carver and the Joiner, whoſe ſeveral Purpoſes it excellently anſwers, that it takes Glue particularly well. It would be endleſs to recount the other common Uſes of Deal, and needleſs, all Perſons knowing them. It is ſufficient that I have ſhewn the Tree which affords that valuable Wood, may be raiſed in ENGLAND with Eaſe and great Advantage. It will be wonderful if ſome of thoſe many Perſons who have waſte Lands on a proper Soil and Situation for this Purpoſe, do not begin: and then the Advantage will ſoon make the Practice univerſal.

CHAP. LIV.

Of the Pine Tree.

THE Reader will naturally wonder why among the ſeveral Kinds of Fir Tree fit to be planted in ENGLAND, I have not named the Scotch Fir. But the preſent Chapter, and not the preceeding, is its proper Place. The Pines and Firs differ by very obvious Characters; and the Scotch Fir, as it is called, is truly not one of Fir, but of the Pine Kind.

The Pine reſembles the Fir in many general Reſpects, but the great Article of the Diſtinction is this, the Leaves of the Fir are ſhort, and grow ſingly from the Branches; though in great Quantities, and near one another; but the Leaves of the Pine are long, and they grow always two together out of a Kind of Sheath or Caſe.

This is the Diſtinction which all Authors have eſtabliſh'd between the Fir and the Pine; and according to this it is very evident, that what is called the Scotch Fir, is one of the Pines, and not of the Fir Kind. Whoever has ſeen a Pine and a Fir, will alſo recollect that the very Appearance of the Scotch Kind is that of the Pine, and not that of the Fir Sort; ſo that the Name is only a vulgar Error.

There are ſeveral Kinds of the Pine Tree rais'd in our Nurſeries; but thoſe worth the Huſbandman's Regard are principally three; the common Pine, the wild Pine, and that called the Scotch Fir. They all bear Cones for Fruit, reſembling thoſe of the Fir, which from that obtain'd the Name of Pine Apples; but the Scotch Kind is diſtinguiſh'd from the reſt by the Smallneſs and Whiteneſs of its Cones. Its Leaves alſo, tho' longer than thoſe of the Fir, are ſhort in Reſpect of others of the Pine Kind.

Theſe three Sorts all delight in a ſtony or chalky Soil, with an elevated Situation. They will grow in the ſame Soils, and on the ſame Kind of Hills with the Firs, and there is no Doubt but that Plantations of them might be made, with the greateſt Succeſs, in many Parts of ENGLAND. We ſee them thrive very well in ſome Places, where they have been raiſed within the laſt twenty Years; and if they have failed in others, it is altogether owing to the Ignorance of thoſe who undertook the Buſineſs. There are ſome Soils which will not ſuit them; and if they are againſt Nature planted in theſe, they muſt either periſh, or at the beſt keep barely alive, without flouriſhing.

As the Soil which agrees with the Pine, is the ſame with that fit for the Fir; and the Fruit is alſo of the ſame Kind: the ſame Method of raiſing theſe Trees is to be uſed as was deſcribed in the laſt Chapter for the Firs, therefore there needs not be a Repetition of any Part of it in this Place.

Beſide the Uſes of theſe Trees as Timber, there is another Advantage to be conſider'd in Reſpect of them; which is that Quantity of Pitch, Tar, Roſin and Turpentine, which they yield, and of which there is a vaſt Profit made in FRANCE, and many other Kingdoms.

We have Soils and Situations fit to raiſe them, and the Manner of doing it is very eaſy, and has been here laid down at large. There can be no Doubt of ſuch a Plantation anſwering to the Expence and Trouble, were there none of theſe Advantages: but when it is found that they thrive here, and we have Plenty of them of a proper Growth, it will be very well worth while to try, whether or not theſe ſeveral valuable Articles of Commerce, may not be procured from them here as well as elſewhere. The Methods by which they are obtain'd are very eaſy: they are deliver'd at large in many Books; and in Caſe of Difficulties, it would be eaſy to bring over Workmen from the Places where they are conſtantly made, to enſure the Succeſs. This may be underſtood as a remote Conſideration; and it is therefore I do not enter upon it more at large here: but the general Method is ſo eaſy, and may be expreſſed in ſo few Words, that 'twere pity to omit it. They cut down thro' the Bark off the Pine Trees in Spring, and there runs a clear Roſin in great Quantities. They ſtrain this, and the fine Part is what we call common Turpentine, of which there is a vaſt Conſumption among Farriers, and many other Trades. The coarſe Part is diſtilled with Water, for Oil of Turpentine, and what remains in the

the Still is common Rosin. The Pitch and Tar are made by burning the Wood in a close Place, which they cover up while burning, and the Juice which runs out in vast Quantities is Tar; and when it is boiled up to a Thickness it is Pitch.

Nothing can be easier than all this, appears in the Description, and Experience only can shew, whether it may not be as easy as advantageous in the Practice. If one Set of these Products could not be obtain'd from the Pine Tree rais'd in England, the other might: if there could be a Difficulty about the Rosin or Turpentine, there can be none about the Tar and Pitch. That they may be made here is beyond a Question, and they are of sufficient Value to make it well worth a Trial.

CHAP. LV.

Of the Juniper.

AFTER the mention of these tall resinous Trees, it may not be improper to introduce a low Shrub, which is in some Degree of their Nature, and which is a Native of our Country, the Juniper. I shall not speak of it as a Kind that can be made to yield any very great Profits; but we see that it naturally grows on our worst Ground, such as the barrenest of our Heaths, and nothing could be so easy as to plant such Places entirely with it. There can be no Doubt of its growing and thriving there, because it does that naturally; and if there be among these Grounds, any that cannot be put to a better Use, it will certainly be an Advantage to raise this upon them, rather than to let them lie absolutely waste and desolate.

The Juniper, although a small Shrub in England, rises to a considerably large Tree in some other Parts of Europe, and it would be worth while to raise it from Seeds of those Trees, carefully gather'd for that Purpose, and see whether we could not then get it to the same Stature on our Heaths and Commons.

The Bark is of a reddish brown, and smooth; the Leaves are small and narrow, of a fine bright green, and prickly. The Flowers are small and inconsiderable; the Fruit is a round Berry: it grows on a different Part of the Tree from the Flower, and is soft and pulpy, with three Seeds within.

The natural Soil of the Juniper is a light, loose, and sandy Earth, it will grow on this though it be very barren; and will bear any Exposure; but it succeeds best where there is a firm Bed under the Soil.

It is propagated from the Berry, which takes very readily, and shoots quickly; and with a little Care at first, will be soon out of the Way of any Accident.

I would advise the Husbandman who should think of such a Plantation, to get some Correspondent to have a Parcel of Berries gather'd from the large Tree Junipers abroad, and carefully sent over.

The Ground should be broken with two good Plowings; and in the Beginning of March, the Berries should be sown on it pretty thick, harrowing them well in. They will lie in the Earth till the next Spring; so that at proper Times a Person should be employ'd to go over the Land, and weed it carefully: when they begin to appear, it will be of great Use to sprinkle some Furze Bushes over the Ground by way of Shelter and Defence, removing them as the Plants grow up.

The next Spring the young Plants should be thin'd, and left at about four Foot Distance; and after this Time they may take their Chance, for they are hardy enough to shift for themselves: only that at the End of one Year more, the Husbandman should go over his Ground, and cut down about half of them within five Inches of the Earth, leaving the fairest and best growing Plants standing entire. By this Means he will have a very beautiful Evergreen Plantation, part Shrub, part Tree, and after a little Time he may send People annually to gather the Berries; which, if the Soil and Situation favour the Trees, will be produced in considerable Plenty, and will always bring a ready Price from the Distiller or Druggist.

The Wood of the Juniper, when it grows to any Size, is of considerable Value. It is yellow, of a fine close Grain, and extreamly tough. It has a very fragrant Smell, in some Degree resembling that of Cedar; from which many People have been led to call the Junipers of the different Parts of the World, Cedars. The Virginian Cedar, the Bermudas Cedar, and the like, being really no other than Junipers.

The Juniper Wood is excellent for Turning, Carving, and many of the finer and more delicate Uses. When large enough, its Grain is so beautiful, as well as its Colour, that the Cabinet-makers would be ready enough to purchase it at a good Price.

Upon the whole; the Cultivation of the Juniper is so easy, and the Ground on which it would grow is so cheap, that it must be very well worth while to try at the raising it to a considerable Value, of which there is a very fair Prospect, since there is a Certainty of its sufficiently answering the Expence and Trouble.

CHAP. LVI.

Of the Yew Tree.

THE Yew is a Tree like the Juniper, of less Value, and less frequent Use than the Generality of those that have been spoken of; but which will in the same Manner grow in Places where Trees of more Value cannot find Nourishment, and is therefore very well worth the Notice of the Husbandman.

It is an Evergreen Tree, which, when suffer'd to grow at large in a favourable Soil, will arise to a considerable Height, and a proportion'd Bulk of Body, but without any great Beauty or Regularity in its Branches. The Bark is of a pale reddish Colour, as is also the Wood: the Leaves are of a very dark blackish green: the Flowers are small and inconsiderable, and the Berry stands in a red juicy Cup,

ſo that it, in ſome Degree, has the Appearance of an Acorn in Miniature.

The Uſe of the Yew in Gardens is well known. Though we no longer allow of the cutting it into Peacocks and Giants, it is in Credit for Hedges which are very thick, and an excellent Defence for the tenderer Growth in the Quarters. But the Huſbandman is to conſider the Yew in another Light; as it may anſwer his Purpoſe in the Fields where it is to ſtand for Timber, without any Regard to its Form.

We find the Yew Tree naturally wild on many of our moſt barren Hills, particularly in Sussex and Hampshire; and in ſuch Places it may be very well worth while to multiply it; for it will thrive perfectly well in the moſt barren Soils; and on the moſt expoſed Places; and after ſtanding a ſufficient Time, for it is not a ſlow Grower, it will yield a very conſiderable Profit.

The common Practice of our Nurſerymen is to raiſe the Yew in ſmall Beds from the Seed, whence they remove it at two Years old to greater Diſtances; and thence, after three or four Years Growth in the new Soil, they tranſplant it into the Gardens, where it is to remain: but the Huſbandman is not to be guided by the Nurſery in his raiſing of Trees. This Method may do very well when the Yews are to be removed into a rich Ground; but as he is to make his Plantations on very bad Soils, he muſt raiſe his Trees on the Spot.

For this Purpoſe let him gather Yew Berries when ripe, from large and tall Trees; and employ People to open the Ground at every ſix or ſeven Foot, where he intends his Plantation.

In each of theſe Holes, thus dug, he muſt ſow eight or ten of the Berries, with the red juicy Part about them; and throwing a Piece of Furze Buſh over every Hole, he is to leave them to take their Chance. They will riſe very freely, and all he will have to do afterward is to pull up the leaſt promiſing of them, till only one Plant is left in each Place. Theſe he ſhould go over every Spring, trimming off the Side Branches, and training them up, as much as poſſible, for a ſingle Trunk.

The Yew wants this Care as much as any Tree whatſoever, for it is apt to ſpread and branch out from the loweſt Parts of the Trunk; and when it takes this Growth it becomes buſhy, and has no Height of Body. It is owing to this, and to the favouring the ſpreading Growth of this Tree in Gardens and Nurſeries, that we ſo rarely ſee a Piece of tolerably large Yew Timber. Here and there an old Tree, that has ſtood at the Head or Foot of ſome Grave in a Church-yard, takes its own Courſe into a tolerable Trunk; Boys cuting off its lower Branches. Otherwiſe we rarely meet with it, and never in the Perfection that it might be brought to with due Care.

The Wood of the Yew Tree is extreamly firm and beautiful: it is generally vein'd with great Elegance, and is capable of a fine Poliſh. Bows were, in old Time, made of it: at preſent it ſometimes ſupplies the Place of Lignum Vitæ, in Bowls, and is greatly admired in whatever Form 'tis met with.

Where large Trees of it have been cut down, People upon the Spot have, in Curioſity, had Tables or other Pieces of Furniture made of it, and they have always been admir'd by all who ſaw them.

The Yew affords a Timber, the Uſes of which are but little known; however, if it were any where ſo rais'd that it could be had in Plenty, and of a good Size and regular Growth, Uſes enough would be found for it. The more irregular Pieces would be employed by the Wheel-wright and Mill-wright, and would make Poſts, and many of the Country Utenſils; and the regular and even Parts would bear a Price with the Cabinet-maker and Turner; being ſuperior, in all Reſpects, to a great many Kinds which they conſtantly uſe, and which they buy at a large Price.

CHAP. LVII.

Of the Box.

WE are deſcending to the Conſideration of Trees of much leſs Value than thoſe named in the firſt Chapters, but they are ſtill ſuch as have their Uſe, though leſs conſiderable, and from certain Circumſtances of their Growth they may be worth the Huſbandman's Notice, ſince he may often raiſe them to Advantage.

The Box is a very little Tree, its Bark is yellowiſh, its Wood very firm, and alſo yellow; the Leaves are each compoſed of ſeveral ſmaller, ſet on the two Sides of a middle Rib, and theſe are roundiſh, of a dark Green, and continue all the Winter: the Flowers are ſmall and inconſiderable, the Fruit grows on another Part of the Tree, and is divided into three Portions, containing two Seeds in each Diviſion.

We uſually diſtinguiſh two Kinds of Box, a Dwarf Sort that is us'd to ſet round Borders in Gardens, and one that is taller, called the Tree Box. This laſt is the only Kind worth the Huſbandman's Notice. Beſide theſe two, there is a narrow-leav'd Species; but its Timber is not ſo fine as that of the common Sort; though the Difference be not great in this Reſpect, any more than in their outward Appearance.

The Box loves a poor Soil, and a bleak Expoſure. It will grow upon the barreneſt and worſt of our Lands, whether they be ſtony, chalky, or of whatever other Kind. So that there are many Places where nothing better will grow, and where it may be uſeful to raiſe it.

The common Way of propagating Box in our Nurſeries is from Cuttings, which they keep well ſhaded and water'd, till they take Root; but this is not the Practice to be obſerved by the Huſbandman who would have this Tree on his barren Grounds.

He may raiſe it from Seed, and that muſt be done upon the Spot, in the ſame Manner as has been juſt directed for the Yew, or he may plant it from Layers, as directed of the Elm. Theſe take Root freely enough. If the Ground have any Richneſs, this is the beſt Method; but where that is very poor the Way from Seed is to be preſer'd.

Which ever Way they are rais'd, the Huſbandman muſt go over his young Plantation once a Year, to take off the large Side Shoots, and

train up his young Trees to a Trunk. They will by this Management, riſe to an Height and Bigneſs, of which they would have no Imagination who had not ſeen them when they grow freely, as on BOXHILL in KENT, and ſome other Places; but in theſe they do not arrive at that Height and Value they will do when train'd for it from the Beginning.

The Wood of the Box, when of any tolerable Size, is of conſiderable Value; and when rais'd to the Bigneſs and Regularity that it would attain, by the proper Methods here directed, few have any Notion of the Price it would bring. It is the heavieſt of all our ENGLISH Woods, and one of the firmeſt and hardeſt: its Colour is very beautiful, and the Grain fine. It is uſed at preſent for the making of Mathematical Inſtruments, and many other Things that require Strength and Firmneſs in a ſmall Body, as Combs and the like. The Turner alſo is glad of it on many Occaſions; and would be on many more if he could have it of a Size for his larger Works; and this would eaſily be brought about, by the proper training of it up, and giving it Time for the Growth into a well-bodied and regular Tree.

CHAP. LVIII.

Of the Cypreſs Tree.

THE Cypreſs is another of thoſe Trees which, though at preſent confin'd in a Manner to the Garden, might be brought out into the Field with Advantage; and which, though not ſo large as many others, is very valuable.

The Cypreſs is an handſome Tree, and when the right Kind is planted, arrives at a conſiderable Size. The Leaves are flat, and as it were ſcaly; the Bark is uneven and brown, the Flowers are ſmall and inconſiderable, and ſtand at the Ends of the Branches; the Fruit grows on other Parts of the Tree, and is roundiſh, hard, and woody: it cracks when it is ripe, and contains in its different Diviſions ſeveral hard Seeds.

There are two Kinds of the Cypreſs Tree, one which naturally grows up erect, and the other which ſpreads its Branches. The ſecond, which is known by the Name of the ſpreading or the male Cypreſs Tree, is to be preſer'd. There is beſide theſe another very unlike them, except in the Fruit: it is brought from AMERICA, and loſes its Leaves in the Winter, whereas the others are green all the Year. This is not worth the Huſbandman's Notice; the Wood of the ſpreading or male Cypreſs, being greatly preferable to that of any of the others.

The proper Soil for the Cypreſs is a warm Gravel: it will grow on ſandy Grounds, but does not thrive ſo well as in the other, among which there is uſually a Mixture of loamy or marly Earth.

It ſucceeds beſt in an elevated Situation, but ſhould not be planted on entirely expoſed Places; on the Side of an Hill, where there are Springs at a moderate Depth, and where there is the Defence of Hedges or Trees, it will thrive excellently. There are many Pieces of Ground of this Kind, on which at preſent nothing of any Value grows, which would carry up the Male Cypreſs to great Value.

This is one of thoſe Trees ſo utterly neglected, that 'tis hard to ſay what is its Value; but the Eſteem in which its Timber is held in other Countries at preſent, and the Value that was ſet upon it in earlier Ages, ſhews very plainly that 'tis not without a Title to the Huſbandman's Care.

The Cypreſs is to be propagated by ſowing the Seeds; and to this Purpoſe the Huſbandman's firſt Care ſhould be to get them good, which he will not eaſily do in ENGLAND, for though theſe Trees bear Fruit with us, it does not ripen perfectly.

I would adviſe the Planter of Cypreſs therefore to procure ſome well ripen'd Fruit from ITALY, and to ſow the Seeds with due Care in his Ground.

In the firſt Place, the Fruit is to be laid at a Diſtance before the Fire, till warm through, upon which the Cells will begin to open, and the Seeds may eaſily be pick'd out. But Care muſt be taken that the Heat be not too great, becauſe that would deſtroy their Power of Growth.

Theſe are to be ſown in the Middle of MARCH, upon the Ground where they are to ſtand, Spots being dug and prepar'd at ſeven Foot Diſtance for that Purpoſe.

Ten or a dozen Seeds are to be ſown in each Spot, and when they are come up, and have advanced a little in Growth, the young Plants are to be pull'd up, till only the one flouriſhing Shoot be left in each Spot. Theſe are to be train'd up for Timber, by cutting off the ſpreading Branches with Moderation, for the Tree naturally ſpreads, and too much Violence muſt not be done to that general Form of growing, leſt it be ſpoil'd.

Little Care is requir'd after the Trees are once eſtabliſhed, but they take Time; for the Cypreſs is not one of the quick Growers.

The Timber of the Cypreſs is of great Value, its Texture is cloſe, and 'tis of a firm Body and fine Grain. It is excellent for Cheſts for keeping of Cloaths, the Moth never coming near it; and no Wood whatſoever is more durable, perhaps none ſo much. It was antiently a Cuſtom to bury in Cypreſs Coffins. And they laſted ſurprizingly. The Wood is undoubtedly excellent for many Uſes, and there only wants a Supply of it. The Turner, the Cabinet-maker, and the Joiner would ſoon find Uſes enough for it, if it were once brought to the Market, for it is greatly preferable to many of the Foreign Woods, which they purchaſe at a very conſiderable Price. And the worſt Pieces of it would be fit to be employed on all the common Occaſions, in which Strength and Durability were requir'd, for it will ſtand wet or dry beyond almoſt any other Wood.

CHAP. LIX.

Of the Cedar.

THE Cedar is another of the Trees which, though rais'd among us only as an Ornament to Gardens, might be very well cultivated abroad in Fields, in proper Places, for the Value of its Timber; the Value of which is ſufficiently known.

Several Trees, as has been already obſerved under the Article Juniper, are called Cedars, which are of that Kind, bearing Berries, and the moſt of them riſing but to ſmall Heights; but by the Cedar is here meant that large beautiful and ſpreading Tree, which is commonly known in ENGLAND by that Name, among Gardiners and others, and is diſtinguiſhed farther by the Name of Cedar of LEBANON.

This is a large and ſtately Tree, with remarkably ſpreading Branches, ſtanding out almoſt flat from the Trunk, and often drooping. The Bark is rough and of a rediſh brown, the Leaves are very narrow, and grow many together in a Tuft, ſo as to reſemble a Pencil: the Flowers are a Kind of Catkins: the Fruit grows on another Part of the Tree, and is a large and beautiful Cone.

The natural Soil and Situation of the Cedar are ſtony and mountainous, nor will it refuſe to live in the coldeſt and bleakeſt Expoſures. The Place where it once grow in the greateſt Abundance of any where in the World, and from whence it has, for many Ages, had its Name, gives Proof of this; for it ſtood in the moſt thriving Condition, on thoſe Parts of Mount LEBANUS which are, in a Manner, all Rock, which are expoſed without the leaſt Shelter, and where the Snow lies to a conſiderable Depth almoſt throughout the Year.

We have many barren, bleak, and rocky Hills in ENGLAND, on any of which it will grow, to which it will be a ſingular Ornament, and where it will yield a very great Profit to the Owner. I hope that one of the Benefits attending this Publication will be, the leading People who have theſe barren Lands, that have lain ſo many Ages waſte, to plant them with ſome uſeful Product. The Cedar is ſo peculiarly fitted for this Purpoſe, that there is no Soil ſo poor as to be too bad for it; and that it will not thrive ſo well on ſuch as is better. Sandy, gravelly, and ſtony Ground, which will give Nouriſhment to nothing elſe, ſupport the Cedar, and raiſe it, in a very moderate Time, to a large and valuable Tree, for though, in general, the Trees which live in watery Places are the quickeſt Growers, the Cedar, though it love theſe dry and barren Soils, is far from being one of thoſe that ſhould be called ſlow.

But though this be the proper Soil of the Cedar, and that wherein it thrives beſt, there is ſcarce any in which it will not live. Cedars are ſeen flouriſhing in the loweſt Grounds, and in Soils abſolutely boggy, in ſeveral Parts of the World: but in theſe they grow very ſlowly and irregularly; and their Timber, when examined, has not its true Fragrance or Beauty; nor its proper Firmneſs.

The Cedar is to be rais'd from Seed, and that ſhould be done on the Places where it is to ſtand when it is thus rais'd for Timber; for the Soils I have directed for it are ſo poor, that a Plant removed into them from any other would have an ill Chance to thrive.

The Cones of the Cedar are to be had from Abroad; there are many of them brought every Year from the LEVANT, and to be had in LONDON. To get out the Seeds an Iron Spike muſt be driven through the Cone lengthwiſe; this rends and ſeparates its Parts, forcing them ſo from their Lodgments, that they may be pick'd out with the Fingers.

Theſe Seeds are to be ſown early in the SPRING, ſix or eight on each Spot where a Tree is intended to ſtand, and theſe Spots ſhould be prepared at five and thirty Foot Diſtance.

A Piece of Furze Buſh ſhould be laid over the Place; and kept there till the young Plants which have riſen from the Seeds are of ſome Height. Then they are all to be taken up, except one, leaving the faireſt and moſt thriving; and to train this up ſtrait a Pole muſt be ſet in the Ground near it, and the leading Shoot gently ty'd to the Pole as it grows. This is particularly neceſſary to the Cedar, which is apt to incline to one Side in its growing.

The young Trees being thus ſecur'd for Straitneſs, are to be left to Nature. They will grow but ſlowly at firſt; but very ſoon after they have arriv'd at a good Fixture in the Ground, they make amends for it, by a ſpeedy ſhooting up; they are not to be train'd for Height in the uſual Manner, by cutting off the Side Branches: for the lopping of all reſinous Trees is prejudicial in the higheſt Degree, and of none more than the Cedar. Therefore when it is thus carried ſtrait in the leading Shoot, by tying it up, the reſt are to be left to Nature, and although a great many large and ſpreading Branches are found on every Side, the Trunk will be ſufficiently nouriſhed, and will riſe to ſuch an Height and Thickneſs, as to yield Timber fit for all the Purpoſes to which ſuch Wood can be uſed.

It is very ſingular, that as the worſt Soils, ſo the hardeſt Seaſons agree better with this Tree, than ſuch as are richer or milder. The Cedar does not always ripen its Fruit with us, but an hard Winter is always found to promote its doing this. It is therefore evident that the Severity of the Cold is of Aſſiſtance to the Cedar, giving it Strength and Vigour.

This may be a farther Inducement to our Huſbandmen and Owners of bleak, barren, and expoſed Land, to plant the Cedar on it, for where a Tree ripens its Fruit preferably to other Places, there doubtleſs it will be more certain and ſecure to ſucceed in a Plantation.

The Size to which the Cedar will grow before it begins to decay, is very conſiderable. We find in MAUNDRELL's Travels, that there are at this Time on Mount LEBANUS, Cedars that appear to be quite ſound, and are between thirty and forty Foot in Circumference in the Trunk; if we could raiſe them to any thing like this in ENG-

England, the Value they would have is eaſily known.

'The Wood of the Cedar is of a beautiful rediſh Colour, and of a fragrant Smell. It is ſufficiently ſtrong, but is liable to ſplit; Care therefore is to be taken in the working it; but when wrought it endures for ever. This is its great Quality; and while it remains entire itſelf, it preſerves alſo what is kept in the Cheſts made of it; no Moth or miſchievous Inſect ever coming into them. We read in the old Authors, aſtoniſhing Accounts of the Duration of this Wood; and by many certain Inſtances we are led to put more Faith in thoſe Relations, than it would be natural to do without Experience.

The Size to which we read of their growing is alſo countenanced by what we ſee at preſent. A Man would ſtart at the Account of a Cedar eighteen Foot in Diameter, and a hundred and thirty in Length, had he not read of that juſt mentioned by Maundrell, and which is to be ſeen by the Curious at this Hour.

There is no doubt but this Tree may be rais'd in England in any Quantity, nor can there be any Queſtion of a Demand for the Timber, and that at a very conſiderable Price, as ſoon as it ſhould be regularly brought to Market.

Upon the whole, it may not be improper to conclude the preſent Part of our Work with this ſhort Obſervation on the planting Timber; that in many Caſes it is preferable to any other Growth, even upon Land that will bear any thing: but in general, the great Advantage to be made from it, will ariſe from the progagating it in Places where other Things will not grow, or in Spots where they cannot conveniently be rais'd.

The ſeveral Kinds of Timber Trees have been here treated of at large, and it will be an Advantage for the Perſon who intends to plant, if he will firſt go through the Account of them all with due Care, that he may be able to ſuit the Growth to the Nature of his Soil, and the Situation of the Land.

We have ſhewn that there is no Soil whatſoever, on which ſome Kind of Tree will not grow; nor any Expoſure which ſome will not bear: but the great Article of Knowledge, in this Branch of the Huſbandman's Buſineſs, conſiſts in the exactly knowing the different Value of each Tree, and the different Kinds that each Land will bear.

Even in thoſe Soils and Situations whereon any Kinds of the common valuable Timber Trees will grow, there are ſtill ſome which will ſucceed better than others; and in order to make the greateſt Advantage from a Plantation, this ſhould be known. In the ſame Manner, even on the worſt there are generally two or three at leaſt that will ſucceed, let him therefore have all theſe in his Eye when he is about to begin a Plantation; and conſidering thoroughly their ſeveral Advantages, and the Circumſtances of the Ground, let him take Care to chuſe that which will be moſt ſure of Succeſs, and to bring the greateſt Profit. It is not ſufficient that he know how, by this Means, to turn his worſt Land to Account; but he ſhould know how to turn it to the greateſt that it will bear.

End of the Fourth Book.

A COMPLEAT BODY OF HUSBANDRY.

BOOK V.

Of the Animals neceſſary and uſeful in Huſbandry and Farming.

In FOUR PARTS.

I. *Of* CATTLE.

CHAP.
1. *Of the Horſe in general.*
2. *Of the Choice and Management of Horſes for the Farm.*
3. *Of the Saddle Horſe for the Huſbandman.*
4. *Of breeding of Horſes.*
5. *Of weaning Foals.*
6. *Of breaking Horſes for Service.*
7. *Of the Farmer's Number of Horſes, and their working.*
8. *Of the turning Horſes to Graſs, and taking them up.*
9. *Of the Aſs.*
10. *Of the Mule.*
11. *Of the Bull, and his Kind.*
12. *Of the Ox.*
13. *Of the Cow.*
14. *Of the Calf.*
15. *Of Sheep, and their ſeveral Breeds in this Country.*
16. *Of the Choice of Sheep.*
17. *Of the breeding of Sheep.*
18. *Of the ſhearing of Sheep.*
19. *Of the breeding up of Houſe Lambs.*
20. *Of Hogs, their Advantages and Evils.*
21. *Of the ſeveral Breeds or Kinds of Hogs.*
22. *Of the feeding of Hogs.*
23. *Of Goats.*
24. *Of the Rabbit in general.*
25. *Of the wild Rabbit.*
26. *Of the tame Rabbit.*
27. *A profitable Method of keeping Rabbits.*

II. *Of* FOWLS.

CHAP.
28. *Of the Cock and Hen, their Kinds and Choice.*
29. *Of the breeding of Poultry.*
30. *Of the bringing up of Chickens.*
31. *Of Capons.*
32. *Of Turkeys, their Kinds and Choice.*
33. *Of the breeding and raiſing of Turkeys.*
34. *Of Geeſe, their Kinds, and the Profits of keeping them.*
35. *Of the breeding and feeding of Geeſe.*
36. *Of Ducks.*
37. *Of the keeping of wild Water Fowl, and of Decoys.*
38. *Of the Swan.*
39. *Of the Peacock.*
40. *Of the Pheaſant.*
41. *Of the Pigeon.*

III. *Of Fiſh.*

42. *Of the Advantage of Fiſh Ponds.*
43. *Of the making of Fiſh Ponds.*
44. *Of the ſtocking of Fiſh Ponds.*
45. *Of feeding, preſerving, and taking the Fiſh.*

IV. *Of* INSECTS.

46. *Of Bees, their Nature and Products.*
47. *Of the Hives, and the Manner of placing them.*
48. *Of the ſwarming of Bees.*
49. *Of hiving the Bees.*
50. *Of preſerving the Bees.*
51. *Of taking the Honey and Wax.*

The INTRODUCTION.

Of ſtocking the Farm.

WE have in the four preceeding Books inform'd the Huſbandman concerning the Nature of his Soil, the Advantages of Incloſure, the Uſe of Manures, and the Benefit of Plantations; we are in this to advance to the great Article of ſtocking his Farm.

When he has made himſelf acquainted with the Nature of every Part of his Ground; when he has fenced, planted and prepared it for his Undertaking, it is then ready to receive his Cattle: part of which are to be fed upon its Produce, and part employ'd alſo in the Labours of tilling and improving it. Theſe are neceſſarily a great Expence, and they are expected to produce and yield him a proportionable Profit. This they are in their Nature qualified to do; but this Profit will be greater or leſſer, in Proportion to his Skill in ordering and managing of them according to their ſeveral Natures.

From ſome of theſe he is to have Labour; from others Food, and Articles of Trade; and from all of them properly managed, he may have many occaſional, and, as it were, accidental Profits. The Horſe is to ſave him the Toil of his Servants in many Things, the Ox and Sheep are to ſupply his Kitchen, and the Market; as alſo, the Hog, and other Kinds; but the home Conſumption is not all the Source of his Profits: many of their Parts and Products are exported at a great Price; and he will be able to make the more Advantage of his Stock, as he is the better inform'd of every one of theſe ſeveral Particulars; and adapts his Care to ſuch of them as his Circumſtances and Situation render the moſt immediately advantageous to him.

He is to conſider his Cattle with Reſpect to their Food, and its ſeveral Kinds, and with regard to that great Article, their Dung, the Uſes of which have been fully treated of already: this will lead him to enquire into their proper Management in the Field, in his Yard, and in the Stable. The ſeveral moſt beneficial Methods of regulating their Food, Litter, and Standing, will be a very principal Object of our Attention, under their ſeveral Heads in the ſucceeding Chapters. In which, proceeding upon that ſure and certain Guide, Experience, we have Hope of leading him to a much more beneficial Method of conducting himſelf in ſeveral Reſpects than is generally known at this Time.

In this Place it may be neceſſary to caution the Reader not to ſuppoſe us deficient with Reſpect to thoſe Articles; which, altho' they regard Cattle, are reſerved according to the Original Plan of our Work, to diſtinct and ſeparate Parts of it.

In this Place we are to conſider the Huſbandman as purchaſing his Stock, and diſpoſing and employing it on his Land; after which we are to proceed to the immediate Labours to be employ'd upon it. The ſeveral Products of his Stock in Hide, Tallow, and the other Articles are to be conſider'd hereafter in their proper Place; as alſo the Diſeaſes to which the ſeveral Kinds may be incident; for we do not ſuppoſe him to purchaſe one Kind labouring under Diſtempers; or to intend the immediate ſlaughtering of the others. Theſe Things therefore are to be treated of hereafter, and in the preſent Part of our Undertaking, we are to conſider the ſeveral Creatures themſelves; their Service, Breed, Management in every Reſpect; and the ſeveral Methods whereby they may be render'd moſt beneficial to him while he keeps them, and moſt advantageous in the Sale, when it is proper he ſhould diſpoſe of them.

We ſhall divide theſe Animals as they concern the Huſbandman under four general Heads, two larger and more important. 1. His Cattle and his Poultry; and two leſſer, but yet very worthy of his Conſideration. 3. Fiſh; and, 4. Inſects.

The two firſt of theſe every one is ſenſible, demand the moſt careful Attention, as on them depends a very conſiderable Part of the Farmers Expence, and his Profits; the two latter are not ſo much regarded as they deſerve, eſpecially the Article of Fiſh. We hope to be able to ſet that Article in ſo true a Light, that the Huſbandman ſhall for the future underſtand it as one of the regular Parts of his Occupation, and not the leaſt in Profit.

BOOK V. PART I.

Of CATTLE.

CHAP. I.

Of the Horſe in general.

WE are ſenſible Volumes might be written on the Horſe, for Volumes have been written on it already, and the Subject is not exhauſted: but the Buſineſs here will be to ſelect from all that has been ſaid, and may be ſaid on this copious Subject, that which is to the immediate Purpoſe of the Huſbandman.

We ſhall endeavour therefore to ſeparate the uſeful from the ſuperfluous and oſtentatious; and no more to omit any Part of the one, than load this Treatiſe with any of the other. It is not the Purpoſe here to conſider the Horſe as the Racer, or in the Manage, but as the uſeful Servant of the Huſbandman, who is to buy him for his Purpoſes, with Remembrance, that if he can

breed from him, ſell him at an Advantage, or any other Way make him produce a certain Profit, 'tis all within the Compaſs of his Profeſſion. We would no more have our Farmer a Jockey, than we would have him a Sportſman; but ſo much of every Branch that regards this Animal, as may be uſeful to himſelf, without tranſgreſſing the Bounds of his proper Profeſſion, we would have him know, and ſo much we ſhall endeavour to inform him.

The Diſeaſes to which this noble Animal is ſubject are very numerous, and very little underſtood. Theſe deſtroy many a uſeful Creature that might be preſerv'd with a little proper Care; and it is not too much to ſay, that after all that has been written on this Matter; after the innumerable Bundles of Receipts in old Authors, and the Diſcoveries, great as they are, which have of later Time been made by ingenious Foreigners, as well as by our Gibson, Bracken, Bartlet, and the reſt, there is no Book in the English Language ſo much wanted, as a compleat Syſtem of Farriery.

It is not within the Compaſs of our Undertaking to enter upon ſuch an Article at large, nor is any more than a ſmall Part of what might be ſaid on that Head neceſſary to the Farmer; but that Part we ſhall endeavour to lay down in its Place, by the Aſſiſtance of many Enquiries, and a long Experience, if not in a compleat and accurate, at leaſt in a uſeful Mannner.

It is but of late that the Conſideration of Horſes has fallen into the Hands of thoſe who had any of the Requiſites for being capable of a due Care of them. Farriers have been uſed to be of the moſt ignorant among Mankind; and every Blackſmith called himſelf at one Time a Horſe Doctor. Of late the great Uſe of this noble Creature in our various Concerns of Buſineſs and Pleaſure, has reſcued it out of ſuch Hands, and made it a ſubject for more Education and Abilities; and though the Practice be yet far ſhort of Perfection, great Advances have been made in it, with which the Huſbandman ſhould not be unacquainted.

So ignorant have the old Writers on theſe Subjects been, that they are continually miſtaking the very Seat and Place of the Diſeaſes in this Animal; and at this Time nothing is ſo common, as to ſee thoſe who know no more of the Creature than what they read in thoſe erroneous Books, rowelling and burning a Horſe in one Place for a Diſorder, the Seat of which lies in another; and in one which cannot be affected in any Manner by what is done.

This may ſtand as a general Inſtance of that Ignorance which reigns too univerſally with reſpect to Horſes: excepting for the Cheats of Jockeyſhip, People are as unſkilfull in every other Reſpect; for all that ſeems to be ſtudied now about a Horſe is, how to cheat the Purchaſer.

What reſpects the Diſeaſes of this Creature, will be explain'd hereafter under its proper Head; and here we ſhall endeavour to ſet the Huſbandman as right with reſpect to the Nature and Kind of his Cattle, and his Management of them in Food, and at Labour.

Horſes, though all of one Species, may be divided into many Kinds according to the different Services for which they are deſign'd. Thoſe for the nobler Exerciſes, or the Uſes of Pleaſure, demand a great deal of Care and Trouble, as well as a large Expence; but the Farmer's Horſes, which are for Labour only, require comparatively very little of either.

Let him not take his Directions concerning them therefore from Books, where the principal Regard is ſhewn to the Racer, the Hunter, or the manag'd Horſe, for theſe do not belong to him: the plain and cheap Practice uſed for the Cart Horſe, and the poorer Sort of Road Nags, is all that concerns him: this he will find here laid down from repeated Trials, and let him compare it with the Management of his Neighbours, in order to ſee how it agrees with that, and how it excels it; for we would have him learn not only from what he reads, but what he ſees; and improve his Knowledge from the Miſcarriages as well as the Succeſs of others.

CHAP. II.

Of the Choice and Management of Horſes for the Farm.

IT is a Thing of great Concern to the Huſbandman to proportion the Number and Kind of Horſes to his Farm, and he is alſo to conſider the Sex. For in ſome Caſes breeding from them may be a Thing of great Advantage, and under other Circumſtances, it will not be prudent in him to think of it.

I have obſerv'd already that a certain Proportion ſhould be kept up as near as may be between the Arable and Paſture Land of a Farm; but this cannot in the Nature of Things be always done ſo exactly in Practice as might be wiſh'd from Theory. Now the Exceſs in either Kind, where it cannot be avoided, will give the Huſbandman a proper Caution as to the Sex of this Cattle; as the Nature of the Employment for which he wants them will for the Kind.

The Horſe for Plow muſt be ſtrong, no matter for his Shape. But for Cart ſome Care ſhould be uſed in the Choice, and in the Size. Theſe ſhould be big breaſted, large bodied, and ſtrong limb'd; and they ſhould always be bought of a moderate Size, not only that they may match with one another; but that others may eaſily be got to match with them when any die, become uſeleſs, or are ſold out.

The having Horſes for ſlow Draught all of a Size, or nearly ſo, is a very conſiderable Article; for otherwiſe the Team never work equally, nor at Eaſe to themſelves; and the Huſbandman has not the Advantage of half their Strength, though they go through an equal Fatigue: the tall Horſes hanging up the low, and it being altogether impoſſible that they ſhould draw evenly together.

It is a Benefit in the Horſe intended for this Service to be ſluggiſh: the fitteſt for it are ſuch as require the Whip, rather than ſuch as are ready to draw more than needful.

On

One thing more I ſhall obſerve to the Farmer, which is, that he avoid that very common Fault; the making one Horſe ſerve for different Uſes. Nothing is ſo wrong. Let him never put a Saddle upon his Cart or Draught Horſes, for it alters them in their Pace, and renders them aukward and troubleſome in their ordinary and proper Labours.

After the Kind, let the Huſbandman conſult the proper Sex of theſe Cattle, and in this, as I have obſerved, he is to be directed by the Nature of his Farm, and the Proportion of one Kind in his Land to another.

Mares are naturally more profitable than Horſes, becauſe, beſide their Labour and Service, they yearly will bring forth a Colt. But let not the young Farmer reſolve at once, for this Reaſon upon the buying that Sex, he muſt look farther. If he have a great deal of Paſture Ground, in proportion to his Arable, then he will do right to ſtock himſelf with Mares; but on the contrary, where the Arable Land is the greateſt Quantity, and the Paſture but little, he will find it much more to his Advantage to have Stone Horſes or Geldings.

We ſee that in ſome Counties the Farmers in general purchaſe Mares, and in others they in general keep Horſes for their Service; and this, at firſt Sight, may ſeem idle; but it is founded on this Rule, and on what they find anſwer beſt upon Experience, becauſe their Lands are ſo diſpoſed. In ſome Counties the Arable is in general over-proportioned to the Paſture Ground; and theſe are the Places where they keep Horſes moſtly; and in others the Paſture Ground in general over-ballances the Arable, and theſe are the Places where the Run is upon Mares.

When the Nature of the Farm thus recommends it to the Huſbandman, to purchaſe Mares rather than Horſes, he is to remember that it is of more Importance to him to conſider their Shape: becauſe on that will, in ſome Meaſure, depend the Value of the Breed.

Let him chuſe his Mares with a good Forehand: the Neck, Breaſt, and Shoulders are, in this Reſpect, to be his principal Regard; for as to the reſt of the Shape it is not of ſo much Conſequence.

But though he don't much regard the Shape, let the Body be large; for it is a great Advantage to the Foal to have Room, while it is growing in the Mare's Belly.

The Foals that the Huſbandman ſhall have from Mares thus choſen, will pay him very well for his Care: they will generally be well-ſhaped; and it may be worth his while to ſell them at about ſix Years old, when they will uſually bring a fair Price.

Nor let him think that the keeping them to this Age before he diſpoſes of them, is any Hardſhip; for their Work, the greateſt Part of the Time, will very well pay for it.

This is ſo certain, that where the Huſbandman has not the Advantage of breeding, from a Deficiency of Paſture Ground, it is worth his while to buy Colts young, and train them up to that Age for Sale. This is practiſed in many of thoſe Counties where the Arable in general exceeds the Paſture; and it is very well known in particular, that the Huſbandmen of HERTFORDSHIRE buy Foals out of LEICESTERSHIE, which is a good breeding County, to ſell again at an Advantage. They buy them at two or three Years old, and ſell them again at ſix. The Foals improve every Year; their Labour anſwers very well for their keeping, and at the End of this Time they are fit for Coach Horſes, and are commonly ſold in LONDON for that Purpoſe.

In ſome Counties an ordinary Sort of Horſes are much required for Carriage of Loads, as Packs, Panniers, and the like. When the Huſbandman wants a Creature for this Uſe, let him obſerve to chuſe him of a ſtout Make, but not tall. Let him have a broad Back, out Ribs, full Shoulders, and thick Withers. This is a very material Circumſtance; for an Horſe that is thin in that Part is always galling: which is a very great Inconvenience to Horſes that are to carry Burthens.

After his Shape, let the Purchaſer obſerve his going, and examine carefully his Pace. That Horſe is beſt for this Service that takes the ſtouteſt and beſt Stride with his Feet. He is neither to trot nor gallop: all his Buſineſs is a Foot-Pace; and for this Purpoſe the Horſe that takes the largeſt Steps, always goes eveneſt and eaſieſt, and rids Ground the faſteſt.

The Horſes being purchaſed for the Farm, according to the ſeveral neceſſary Labours of the Plow, the Cart, or Carriage, the next Thing to be conſider'd is, their Management; and this is very eaſy. Theſe Creatures which are deſtin'd to coarſe Service, require nothing of thoſe pamper'd Methods which are needful to the fine Horſes, that are rendered delicate by Idleneſs. They require nothing of thoſe Walkings and great Care, and nice Dreſſings, but what they do require let the Farmer ſee they have duly and regularly.

Let them be well dreſs'd, and their Bellies well fill'd: for otherwiſe they will never be able to go through their Taſks of Drudgery. Let their Shoes and their Backs be conſtantly looked to; and little or nothing more is neceſſary.

Let their Food be ſweet Hay, or of other common Kinds ſingle, or mix'd together, according to the Owner's Convenience: once in a Week or ten Days let him always give them ſome warm Grains and Salt: this will keep them in Health: for they will eſcape moſt of the common Diſorders of Horſes, by their conſtant Exerciſe and Labour, with this little needful Care.

For what may be farther needful, according to the particular Circumſtances and Condition of the Horſe, I ſhall in a few Words obſerve. That if bleeding appear requiſite, Spring or Fall is the Time, or both. If there be Danger of any Diſorder about his Head, it is good now and then to burn a little Frankincenſe under his Noſe, when he is about to lie down at Night. In the Heat of Summer it is very good to take a labouring Horſe into deep Water, and ſwim him now and then.

It will do no Horſe any Harm to be bled every Spring and Fall; but if once this be made into a Cuſtom, let it be regularly obſerved: for ſo ſure as it is omitted he will have ſome Diſorder. Nature expects theſe artificial Diſcharges, if they have been brought into a Cuſtom, as regularly

as if they were her own, and can no more do without them.

A fat Horſe ſhould drink often, and but a little at a Time; but if an Horſe be lean let him drink as he pleaſes.

A great deal of rubbing does a great deal of good: every Horſe likes it, and every Horſe is greatly benefited by it. A Horſe ſhould always be turn'd to Graſs once a Year; for it cools his Blood, ſcours off all foul Humours, and prepares his Stomach to receive the full Nouriſhment from his other Food. Nothing tends ſo greatly to the preſerving the Huſbandman's Cattle as this; nor is there any thing ſo prejudicial to them as the Omiſſion.

CHAP. III.

Of the Saddle Horſe for the Huſbandman.

I HAVE cautioned my Farmer, in the preceding Chapter, not to put a Saddle on the Back of his labouring Horſes; therefore, as his Occaſions will neceſſarily take him frequently on Horſeback, he muſt keep one or more particularly for that Purpoſe; and I ſhall not leave him him defective as to the Kind and Management of that Creature.

Neither need the Horſe, though bought for this Uſe, be ſtrictly kept to that only: he may be ſerviceable on many Occaſions: the Draught, or Load Horſe, muſt not be taken from his Work, becauſe it ſpoils his Pace, but there are many little Services for which the Saddle Horſe will do, when he is not requir'd for that Uſe; and it will do him no Sort of Harm to take him to them as Neceſſity requires.

In the Choice of an Horſe for the Saddle, let the Huſbandman obſerve to get one of as good a Shape as his Price will afford; for it is a general and a very good Rule, that the Value of a Horſe for the Road may be judg'd of by his Truth of Form.

Let him ſee that his Head be lean, his Eyes prominent, or full; and his Neck well rais'd. Let his Chine be alſo well riſen, his Joints ſtrong, and his Raſterns ſhort and ſtrait, and ſo ſtrong as not to bend in his going: and let his Hoofs be ſound, tough, and hollow.

Laſt of all let him examine his Temper and Diſpoſition. In this he ſhould be moderate: too dull a Jade is as bad as a run-away. The Huſbandman wants his Nag for Service, and let him chuſe him ſuch as will do his Buſineſs freely, without continual whipping and ſpurring; and yet will not be eager to go on when there is no Occaſion.

This Care having been taken in the buying of the Horſe, the next Concern is the feeding of him. His general Food ſhould be fine Hay in Winter, and ſweet Graſs in Summer; and to theſe are to be added dry Oats, Beans, Peaſe, or Bread, according to his Stomach or Occaſions.

When he is upon Exerciſe let him be watered two Hours before he is taken out to ride, and let him be rub'd, dreſs'd, and fed; and after this let him be bridled up, and ſtand an Hour before he is mounted.

At ſetting out on a Journey, obſerve always that the reaſonable Method is to travel moderately in a Morning, till the Horſe be warmed, and then to encreaſe the Speed as Occaſion requires.

At Night the Horſe ſhould be watered two Miles before he comes to his Journey's End; and then let him be brought in warm: and let him be ſet up in a warm Stable, well rub'd and well littered.

Let him have no Meat while he is in a Sweat in any Part, but when he is dry let him be rub'd and fed, according to his Stomach and his Duty.

If at any Time the Road Horſe wants Appetite, let the Rider obſerve to change his Food, for theſe Creatures love Variety as well as ourſelves; and will often be tempted to eat new Meat when they would not have touch'd the old. If this do not anſwer, let there be a ſmall Quantity of white Wine, Salt, and Vinegar mix'd together, and let his Tongue and Noſtrils be rub'd with it. This ſeldoms fails to recover his Appetite.

After this let the Rider look well to his Back and to his Feet. Let him ſee that the Saddle does not gall, nor the Girts pinch him; and that the Shoes be large enough, and that they ſit faſt and eaſy.

Theſe are the Directions neceſſary for the managing and preſerving a Road Horſe, in Condition to do his Buſineſs. I have ſet them down at large, that the Huſbandman may fully underſtand what he is to do. The leſs the Buſineſs in long Journies, the leſs of this ſtrict Care is neceſſary: but let it be proportioned to the Duty. 'Tis always well to know the whole that may be neceſſary; and too much Care never did a Horſe Harm.

CHAP. IV.

Of the breeding of Horſes.

WE have ſhewn what is the Huſbandman's beſt Practice in Counties where it is uſually neceſſary to buy Horſes, whether in the Colt or at other Ages; but when he is ſituated in a good breeding Country, there is nothing whatſoever which he can practiſe to more Advantage, than the doing this, both for his own Service and for Sale.

We ſhall therefore lay down here ſuch Rules as may be neceſſary to be obſerved in this Matter, and although the immediate Purpoſe be no other than the breeding of Horſes for the Service of Huſbandry, and the coarſer Employments; yet, as the Farmer may ſometimes ſtep a little beyond theſe ſtrict Bounds to his Advantage, we ſhall not ſo exactly confine our Inſtructions to them, as to diſcard totally the reſt.

The firſt Conſideration that is to fall under the Huſbandman's Thoughts who is inclined to breed, is that of his Ground, for though he live in a good breeding Country, yet every Part of it may not be ſuited alike to that Uſe, and his own Lands in particular may not be convenient for that Purpoſe.

The Ground that is proper for the breeding of

Horſes, is to be of a middle Value between the beſt and the worſt. Horſes are a very valuable Commodity, but let not their Price at a proper Age, and of a good Kind, tempt the Huſbandman to enter raſhly upon his Deſign. Horſes are ſubject to many Accidents and Caſualties; and at beſt they are a long while in riſing to their Value: therefore let him firſt conſider whether he cannot make greater Advantage of his Ground in the common Way of his Employment, for it is very likely that he may. If it appear that he can, then his Land is too good; and he ſhould for that Reaſon drop his Deſign: on the contrary, he may be poſſeſſed of Grounds which as they will not produce much any other Way, ſo they may not be rich enough for this. In that Caſe he is alſo to drop it. In the one Inſtance it is not worth his while; and in the other he cannot accompliſh it: both theſe are very ſufficient Reaſons for deſiſting.

It has been obſerv'd already, that the Condition of the Huſbandman's Grounds which ſhould tempt him to have Mares for the Sake of their Breed, is where the Paſture Land bears an over-proportion to the Arable: but we ſee by the laſt Obſervation, that a certain Condition in this Paſture Ground is alſo requiſite. If it be very rich, it will yield more Profit other Ways than by breeding Horſes; if it be very poor, on the contrary, it will not yield ſufficient Nouriſhment; and therefore it is incapable of being put to this Uſe. The proper Paſture Soil for breeding theſe Creatures, is therefore of a middle Nature.

It ſhould be ſuch as yields a ſhort Graſs, but in a good Quantity: as for Situation, it ſhould be high much rather than low; and the Soil muſt be ſuch as has ſome Firmneſs, for its being hard under Foot is an Article of great Advantage. We would not be underſtood to mean, that an exact Attention to ſuch a Soil as this is neceſſary, or that no other will do, but this is beſt.

There muſt be good Water upon the Ground; and if it be full of Mole Hills, and other uneven Places, it will be the better, becauſe it will uſe the Colts while young to tread firm; and this is an excellent Article in their breeding.

A good Air is a very great Article alſo in a breeding Ground; but as we have already recommended its lying on an elevated Situation, this will be the more likely the Caſe: and further it will be needful that there be good Shelter.

Incloſed Lands of this Kind and Condition are the beſt for breeding, becauſe they are warm and defended; but open and common Land may be uſed; only in this Caſe the Huſbandman muſt be the more careful to provide convenient Shelter; and muſt be more than ordinary careful of the Mares juſt about the Time of their foaling, and of the young when it is yet tender.

When the Huſbandman has a conſiderable Quantity of Land that he deſigns for this Purpoſe, it ſhould be divided into ſeveral Paſtures, according to the Condition and Circumſtances of the ſeveral Parts of the Ground; and theſe ſeveral Incloſures ſhould be uſed to theſe Purpoſes following.

The barreneſt and pooreſt are for the Stallion to run in with the Mares: the moſt under Shelter, and the leaſt ſubject to Accidents, are to be kept for the Mares to foal in: then the fruitfulleſt and richeſt are to be kept for them while they are follow'd by their Foals, and give Milk. Laſtly, for the bringing up of the Colts after they are wean'd, the largeſt, openeſt, and the moſt uneven.

According to the Uſe for which the Colts are deſign'd, let the Stallion and the Mare be choſen. We have already directed what Choice ſhould be made of Mares for the Service of Huſbandry, which is our material Purpoſe: for any other Uſe they are to be ſelected in the ſame Manner, but with regard to that particular Service.

As to the Stallion, he is to be choſen according to the particular Service. The Turkiſh, or Jennet, is an excellent Kind for a Horſe intended for the Wars: the Barb is the beſt for Racers; the beſt for hunting is the baſtard Barb begot of the Engliſh; the beſt for the Coach is the Flemiſh; and the beſt for Travel, Draught, or Burthen, is the Engliſh.

Theſe are Rules long ago laid down, and ſince that Time often diſputed; but they are nevertheleſs maintain'd with Reaſon by the moſt experienced to this Day. Fancy and Opinion ſo far prevail at this Time, that it is ſcarce poſſible to find two People who will not diſpute upon this Subject. However, he who obſerves theſe Rules will not repent: and, as to the material Part of our Buſineſs in this Place, that is the begetting of ſerviceable Horſes for the Huſbandman, the right Engliſh is the Stallion for that Purpoſe, beyond all Cavil or Diſpute whatſoever.

The beſt Seaſon of the Year for putting the Stallions and Mares together is about the middle of March, and the Stallions ſhould be taken away again about the Beginning of May. The Reaſon of this is, that the Time of foaling is of great Conſequence: for the Foal that falls in March is much more profitable than that which falls in May, it having the Advantage of a Part of the Cold of that Seaſon, and the whole enſuing Winter to harden it. Experience ſhews, that this is of great Conſequence: for the Colts foal'd in March are always found to ſtand better, and be leſs liable to Accidents and Injuries than thoſe which fall later in the Year.

The Farmer muſt take Care to have his Paſtures in proper Order for the receiving his Horſes and Mares at the Time mention'd, and for the other Purpoſes ſpecified before; but he will do well to obſerve this Rule, not to make his Mares too fat before the Time of their running with the Stallions; for they conceive better, and hold better when they are in but ordinary Caſe.

It is proper to give the Mares three Weeks Reſt from Labour after the Time of their conceiving: after this they may be employ'd in the common Affairs of Huſbandry, but it is beſt not to work them too hard: the Farmer may, without any Damage, keep them thus to work

till the next Spring; and then he ſhould let them run looſe till they foal.

I deliver this as the beſt Method of conducting Mares that are Breeders, but I do not ſay every Part of it is abſolutely neceſſary to be obſerved. If the Neceſſity of the Farmer's Affairs require it, he may have more Work out of them than I have allowed; but if he allow them ſo much Reſt, they will do the better, and he will have the Advantage in the Foals.

When the Mare has foaled, ſhe ſhould be immediately removed into the beſt Paſture the Farmer has, for this will make her have Plenty of Milk, and that of a good and nouriſhing Quality. The Foal will ſhew the Benefit of this, for he will thrive apace. The Paſture muſt not only be rich, but ſuch as has ſweet Water and good Shelter, eſpecially if the Foal have fallen early: and it will be adviſeable to let the Mare take Care of it a good Part of the Summer: if Convenience allow, it will be uſeful to the Foal to leave him with his Parent the whole Summer, and even the following Winter. There is a Notion that the Winter's Milk is not wholeſome, but it is a weak and idle Fancy. The Farmer is to ſuit all this Practice to his other Affairs, but of this he may be ſure, that if he can allow of it, the Foal will be the ſtronger and better in every Reſpect for running the whole Year with his Dam.

The Foal will partake of the Nature and Qualities of both his Parents, but moſt of the Mare; this is an Obſervation as old as Virgil; but the Horſe is of great Conſequence alſo.

Both the Stallion and Mare ſhould be ſound, if healthy Colts are expected, for they will partake of the Diſeaſes of their Parents in both Sexes.

The Way to have large Colts, is, 1. To chuſe, as before directed, large body'd Mares; and, 2. To feed them well during the Time of their Pregnancy; for the two Things that give Size to the Foal are, good Nouriſhment and Room to grow in. Very large Foals have been thus produced from ſmall Stallions; and of this frequent Experience leaves no Room to doubt.

A great deal of Care ought to be taken to keep the Mares tame, and alſo to make the Colts at firſt tame in the ſame Manner; for otherwiſe the Mares often injure them while in their Bellies, by leaping Hedges and Ditches; and the Foals in the ſame Manner damage themſelves while they are young by their unruly Frolicks. A very good Way of keeping the Mares tame and gentle, is by giving them daily ſome Work, for this accuſtoms them to be tended and handled: whereas when they run free the greateſt Part of their Time, as is the Caſe very frequently among thoſe who can ſpare their Labour, they are difficult to be kept in Order; to be removed from one Paſture to another, as Occaſion requires, or to have the Foals properly tended.

A great deal of Nicety is uſed in the breeding Horſes for the finer Employments, but 'tis the Huſbandman I am directing, and he may in the Manner I have ſhewn, avoid the Trouble and Expence of houſing his Mares, and all that Ceremony commonly practiſed; and he will often have better Foals than thoſe who obſerve the moſt exact Rules; as we ſee frequently, nay commonly, the Children of ordinary People more healthy and ſtrong than thoſe of Quality, who are brought into the World with a great deal more Pomp and Ceremony.

The Age of a Mare for breeding in the beſt and moſt advantageous Manner, is from four to twelve Years old, if ſhe have been employ'd in the common Labour of Huſbandry during the Time; but if ſhe have been kept for breeding entirely, ſhe may be held to it a great many Years longer.

The Age of the Horſe ſhould be from five Years to fifteen.

When Mares are kept altogether for breeding, it may be proper to beſtow ſome more Care and Expence upon them than uſually is done when they breed and work together; and it is the Owner's Buſineſs then to keep them as cloſely to it as may be. In this Caſe it is a good Method to feed them richly for a Fortnight before their foaling, which will give them Strength, and Plenty of Milk: it will make them ready alſo the quicker to take Horſe again.

Where a Mare is thus manag'd, ſhe may be led to the Stallion three Weeks after her foaling; and her Foal may run by her till ſhe comes again.

CHAP. V.

Of weaning Foals.

Notwithſtanding that the common Practice is to wean a Foal at about ſix Months, when that falls out toward Michaelmas, or elſe about ſix Weeks before the Dam foals again, provided that happen in a good Seaſon, we have adviſed the Farmer to let his Colt run by the Dam till ſhe gets another: and in this we are ſupported by very profitable Experience: for upon the Reſult of many Trials it appears in general, that the Colt which has run the Winter with his Dam, is ſtouter and more healthy than ſuch a one as has been wean'd at the Approach of Winter, whatever have been the Care taken of him.

The weaning of a Foal at whatever Age, or particular Time it be done, is an Article of great Conſequence; and upon the proper conducting of it depends in a great Degree the future Value of the Creature. If Care be not taken in the Article of weaning, and in the ſummering and wintering the Colt for three Years afterwards, he will never be worth nearly what he might under this right Management.

The Colt that is to be wean'd ſhould be taken from its Dam over Night, and driven into ſome warm and ſhelter'd Place out of her hearing: it muſt be fed carefully, and well in the Morning; and from that Time thoroughly attended for four or five Days: in that Space it will have forgot the Dam; and may be turn'd out to take its Chance: but Care muſt be taken to keep it out of hearing of the Dam for that

whole Summer, after which there will be no need of any particular Caution.

Such Colts as are intended for Geldings, are to be gelt at the Time of their weaning, and then the ſame Care ſerves, and as ſoon as thoſe few Days already directed are over, the Part will be healed; and will occaſion no farther Trouble.

After this the Colts ſhould be ſeparated from the Filleys, and each Parcel turn'd out apart into ſome open Paſture where they may have Room, and a free good Air; and may run at Liberty till they are fit to be broke for the Saddle, or for the Service of Huſbandry.

Some practiſe the Gelding of their Colts much younger than we have here directed, and when that can be done with Convenience, it is altogether as well. They do it while they ſuck, and as ſoon as the Teſticles come down: ſometimes gelding them at a Fortnight old or leſs.

When it is done at this Time, there ſeldom are any bad Accidents attend it: but on the other hand, all the Damage that appears is a little ſwelling of the Parts after cutting; and this goes down when they have been kept carefully three or four Days, which is what we have adviſed to be done on Account of their weaning.

Theſe two Methods are ſo little different in themſelves, that the Huſbandman may follow which he likes beſt; but if he come to a Reſolution in Time, that while the Colt is very young, and is ſucking, is rather preferable.

For whatſoever Service the Huſbandman intends his Breed, whether for Sale, or for the Uſes of his Farm; and whether he raiſe fewer or more, it will be of great Importance to him to obſerve the Directions laid down in theſe Chapters, relating to their breeding and weaning: that he may not be ſtartled at the Trouble, we have made it as little as poſſible; cutting off all that Experience has ſhewn to be ſuperfluous in the common Practice; but the little that is here ſet down, he is to obſerve carefully: for he will find his Colts the ſtronger and the handſomer for it; and the fitter for his own Service, or for fetching him a good Price at the Market.

CHAP. VI.

Of the breaking Horſes for Service.

IT is ſeen in many Things that the greateſt Advantages depend upon what appear to be ſmall Matters, and is thus in the Caſe before us. I have given the Huſbandman his Directions for breeding his Colts; but he is yet to take the Care of breaking them; and although this is a Point ſufficiently regarded in Horſes of the finer Kinds, yet no Article of Huſbandry is ſo ſhamefully neglected, as the proper Care of firſt training the Horſe to his ſeveral Services in that Employment.

One common Fault on this Head is, the neglecting to break them at a proper Age. The ſparing a little Trouble at a right Time, is the ſpoiling of many a good Horſe.

The Colt that is expected to turn out ſerviceable ſhould be broken early, and uſed gently at firſt. The common Cuſtom is to ſpoil a Saddle Horſe, by making him do too much as ſoon as he is broke; and the uſual Deſtruction of the Draught Horſe for meaner Service is the not breaking him in time.

To avoid theſe common Errors, let the careful Huſbandman take the following Directions. A Year after the Colt has been turn'd looſe from his weaning according to our Method; that is, when he is about two Years old, let him be taken up and gently and gradually tamed. Let him be uſed to the Hand for another Year; and at the Expiration of that, this is when the Colt is three Years old, if he be for the Saddle let him be back'd; or if he be for Draught or Burthen let him be broke to it. But whichever be the Caſe, let it be done gently and gradually. Let a very little be requir'd for the firſt Year; and ſomething more the ſecond, but in Moderation; that he may be regularly brought to his full Strength and Service.

The Saddle Colt ſhould be little more than walk'd the firſt Year; and ſeldom carried beyond a Trot the ſecond; after this there will be no Danger of ſpoiling him, except by unreaſonable Uſage. In the ſame Manner let the Colt be taken up at that Age for Labour in Huſbandry: but the firſt Year let him draw but little; and the ſecond advance his Labour but moderately: thus he will by Degrees be train'd to know his Strength, and how he is to uſe it.

Gentle Exerciſe an Hour a Day is enough the firſt Year; and two or three Hours a Day the ſecond. The Creature does not come to his Strength till ſix or ſeven Years old; and he never thoroughly comes to it at all, if he be too hard wrought while he is younger.

There is no Time nor Service really loſt this Way in the Horſes the Farmer breeds for his own Uſe; becauſe they will ſtand ſerviceable many a Year the longer for this Care and Tenderneſs of them at firſt; ſo that he gets doubly at the End what he loſes by his Gentleneſs in the Beginning; and all the Time of their Service the Cattle are ſtouter, and do ſo much more.

A Horſes ſtanding ſound the Remainder of his Life, is greatly owing to the Treatment of him in the Beginning; and who would ſcruple to forfeit a little of this Creature's Service the firſt two or three Years, to keep him ſound and uſeful all his Life. How long a Horſe will continue ſerviceable is a Point not yet determin'd; nor indeed ever can fairly, except a due Care were taken of them at firſt; but as to their Length of Life, it is more than People imagine. Dr. PLOT, Chap. vii. Page 37. of his Hiſtory of OXFORDSHIRE, mentions no leſs than three Horſes that he had ſeen in that County of about forty Years old a Piece; and the late Duke of MONTAGUE had one which was confidently reported to be not much leſs than fifty. It had been kept without Labour ſeveral Years; but did not ſeem to have been a great many Years paſt Service of one Kind or other.

When the Colt is firſt taken up, he will often be ſullen and unruly: and it is a Neglect at this Age that makes the Horſe vicious all his Life.

In

In this Caſe they muſt be brought to Gentleneſs by Hunger, which will tame any thing. Let the Huſbandman who has ſuch a Colt, ſuffer him to have no Victuals but what he takes out of his Hand.

If this do not bring him down, let him be kept waking Night after Night; for the moſt unruly Horſe in the World, while young, will be broke and rendered tractable in this Manner.

It is a good Method to uſe the Colt to Gentleneſs while he follows the Dam, by giving him good Food from the Hand, and the like Methods; for this will take off that natural Shyneſs and Fierceneſs which there is in every Horſe, till made gentle by Uſe.

Another great Time of a Colt's growing unruly is, when he is firſt back'd, or firſt brought to draw. In either of theſe Caſes the making him go in Company of other Horſes is a very great Thing. When he is firſt rode let it be very gently, with another Horſe before him, and the more about him the better; and in the ſame Manner, when the Huſbandman firſt puts him to work in his Way, let him not be ſet to draw alone, but with others, and let his Taſk be very eaſy and of ſhort Continuance.

It was not without Difficulty that Horſes were originally broke for the Service of Mankind; and ſome Care is yet requiſite to every one of them, at its breaking. The Colt that would fly out, and perhaps do himſelf or thoſe that worked him a Miſchief, if he were employed alone, or ſet to an heavy Taſk at firſt; when the Buſineſs is eaſy, and he ſees others of his own Kind about him, ſoon ſubmits; and then he is eaſily led from the lighter to the harder, and finally to the hardeſt Duties.

CHAP. VII.

Of the Number and working of Horſes.

I HAVE obſerved already that the Huſbandman is to ſuit the Sex of his Draught Cattle, to the Nature of his Ground, that he may have the moſt full Advantage from them: he ſhould alſo, in the ſame Manner, conſider their Kind and Size, for that Sort of Horſes may ſuit with one Farm, which will not do well upon another.

The general Conſideration on this Head is, the Richneſs of the Paſturage, and the Size of the Cattle, for theſe are to be proportioned to one another. The Huſbandman who has rich Ground ſhould breed large Horſes, for they will every way be moſt advantageous to him; and on the contrary, he whoſe Land is poor muſt content himſelf with a ſmaller Sort, except Stone Horſes, if he ſhould chuſe to keep them always at Hay and Oats: in that Caſe he may take what Kind he pleaſes; but this is a Practice not at all to be recommended to the Huſbandman in general.

Horſes muſt be well fed, if they are expected to go through a great deal of Work; and large Horſes will never be ſo upon poor Paſtures. This is a fundamental Rule for the Farmer; and he muſt always keep it in his Memory. It is not eaſy to ſay what Number of Horſes will anſwer the Huſbandman's Purpoſe, for any certain Quantity of Ground. This has been attempted, but the Differences between one Kind of Land and another, in the Degree of Labour they require, makes it impoſſible to determine with Certainty. Upon a general View perhaps it may be reaſonable to ſay, that in Land of a middle Sort, about one Horſe to every ten Acres will anſwer the careful and ſkilful Huſbandman's Purpoſe. He that wants Knowledge and Management, may uſe twice as many, without doing half his Buſineſs.

When the Number of Horſes for the ſtocking of the Farm has been ſettled as well as it may be, the next Care is the proportioning the Work among them: and on this depends a great deal of the Profit that is to be made by this Sort of Cattle.

The young ones we have ſaid, are to be work'd but gently. They may be continually kept doing ſomething at the Harveſt, Seed Time and Fallowing, but they are never to do any thing hard. There are ſufficient Articles of Drudgery in the Farmer's Buſineſs, and theſe he is to throw upon ſuch Horſes as will never be worth any thing by Sale. He is to keep a proper Number of theſe for hard Work, and though they be aged or blind they will anſwer his Ends, provided they are well fed. The ſlight Work of the others, in the mean Time, only accuſtoms them to their Geers, and makes them bring the better Profit upon the Sale.

The Huſbandman who falls into the Method of buying up young Colts, from the breeding Counties, in order to ſell them again at five Years old, muſt take a great deal of Care in the Choice he makes of them: for ſuch as they are, ſuch they will grow up: and the Farmer who breeds muſt, in the ſame Manner, be careful of his Stallions and Mares, according to the Rules given before, otherwiſe he may be greatly diſappointed, when he comes to the Fair with them for Sale. With due Caution there is hardly a more profitable Article in his Buſineſs, for there are always Purchaſers for them, and the Price, if they be well choſen, is very conſiderable: but I have often known the Huſbandman, when he has taken a good Number of them to the Fair, forc'd to ſell them for little, or to keep them on his Hands, either from his ill Choice of the Mares out of which he bred them; or from his little Skill, or little Care, in buying them when Colts.

Blindneſs and other Accidents will happen to Horſes ever ſo carefully bought, or ever ſo carefully bred; but theſe muſt be borne with, all Dealings admit of ſome Accidents: we do not pretend to call that of Horſes one that is more exempt from them than the reſt; on the contrary, it is perhaps as precarious as any; but the more uncertain of Succeſs it is, the more ought the Cauſes of that Uncertainty to be watch'd; and the more needful is a ſtrict Obſervance of thoſe Rules which may prevent the Loſſes that often attend upon it.

As the Horſe is the firſt and moſt conſiderable of all the Animals that are of Service to Mankind, the ſtrongeſt, ſwifteſt, and moſt generally uſeful; it is a Creature that will naturally be of certain and ready Sale: the Variety of

Uſes in which the Horſe is employ'd, will make a Demand for all Kinds, and thoſe of all Qualities. 'Tis therefore an Article of ſo much Profit, and ſo naturally and commodiouſly in the Way of the Huſbandman's Employment, that he ſhould never be deter'd from meddling in it, by Accidents or poſſible Loſſes. This we may, with the greateſt Truth, aſſure him, that his Profits in general will be certain, including all Things, and that the Degree of them will be always proportioned to thoſe two Articles, his Skill and his Care.

By Skill we do not mean that of a Jockey or profeſſed Dealer, for that is rather Artifice and Cunning, and may be called the Art of cheating the Buyer. It is unworthy of an honeſt Man; and it would take off the Farmer from his more uſeful Studies. We mean by Skill nothing more than a Knowledge of thoſe plain and general Facts, laid down here in few Words; and by Care nothing more than his keeping that Knowledge always in his Mind; and acting according to it on all Occaſions.

CHAP. VIII.

Of the turning Horſes to Graſs, and taking them up to the Stable.

TO the Rules already laid down for the general Management of Horſes, I ſhall add ſome particular Cautions and Methods for the conducting that important Point, the giving them freſh and green Meat, and after that, cloſe what is here to be ſaid of this uſeful Animal.

The proper Time for the giving the Huſbandman's Horſe green Food, is in the Beginning of MAY, and the Time for taking him up is toward the End of AUGUST. There are ſeveral Ways of doing this, and I ſhall lay before the conſiderate Farmer, the Advantages and Diſadvantages of each.

In BUCKINGHAMSHIRE, and the neighbouring Counties, the Cuſtom is to turn out the Draught Horſes in the Middle of MAY, into their encloſed Fields of Clover. This is a rank Food, but it is one that gives great Strength and Heart. The Beaſt does his Buſineſs in the more laborious Articles of Huſbandry, more conſtantly and freely upon this Graſs, than any other; and Experience ſhews that he is leſs liable to Colds, and many other Accidents than when fed on the finer Kinds.

In the Conduct of this Matter let me give the Farmer ſome uſeful Hints. Let the Horſes be turned out firſt in the Heat of the Day: and if it be a wet or cold Seaſon, let him take them in at Night, till it is dryer or more favourable.

The moſt healthful Practice is to work them as uſual, while they are at Graſs, taking them up in the Morning, and giving them a moderate Feed of Corn and Chaff, two Hours before they are collar'd; and repeating the ſame after they come from Work. This is of double Uſe, as it keeps them in great Heart; and ſomewhat dries the green and moiſt Food in their Bodies.

In HERTFORDSHIRE it is a common Practice to turn the Cart and Plow Horſes at this Seaſon into a Field of green Vetches, fettering them if there be Occaſion, this is a very ſtrengthening and wholeſome Food.

In other Places the freſh Food is given the Horſes in Racks. To this Purpoſe they mow the Clover, Vetches, or the like, in ſmall Quantities, as they want it, and put it into the Racks: Lucern and Saint Foine may be cut in the ſame Manner with great Advantage.

Another very good Method is to ſow ſome Ground purpoſely for this Uſe with the three Seeds of Clover, Ray Graſs, and common Trefoil together; and cut it freſh for their eating in the Racks: and this keeps them in freſh and in good Heart, under the tighteſt Duty. In theſe ſeveral Methods alſo, by the Help of Straw, there is a great deal of good Dung made for the Service of the Fields.

This freſh cutting of Clover, Vetches, and the like, may be practiſed in Vale Ridge half Acre Lands, as well as in Chilturn incloſed Fields; and it is attended with great Advantage.

Let not any ſuppoſe us deficient in this Part of our Work, becauſe we do not lay down, under the preſent Article, thoſe ſeveral Methods that are preſcribed in Books, and practiſed by Jockeys, of bleeding the Horſes, and all their other Practices upon the Change of Food. It is Idleneſs more than the Alteration of the Diet, that cauſes the ſeveral Ailments into which ſuch Horſes as are bred for finer Services fall, at theſe Seaſons of the Year. The Huſbandman keeps his Cattle to their Labour; and if he does this rightly, it will anſwer the Purpoſe of Bleedings and Drenches much more to his Advantage.

In common Field Lands the Horſe is ſtak'd down with Ropes, where he is put to eat the Graſs: where this cannot be avoided the Farmer muſt be content; but it is a ſorry Method. The Horſe is neceſſitated to drop his Dung and Urine on the Graſs; and he will not eat it immediately after. In this Caſe the Remedy is frequent removing of him, for he will eat the Spot on which he dung'd after a little Time, though he will not while the Taſte is ſtrong in it, and the Dung is there in Subſtance.

An Horſe may be ſtak'd not only on a Piece of Graſs in common Field, but alſo on a Piece of green Vetches, and will thrive upon it very well: but there is the Danger of his breaking looſe in all theſe Places, and in that Caſe he generally does a great deal of Miſchief.

In the ſandy Parts of NORFOLK, and the adjoining Counties, they ſow Turnep for the Summer Food both of their Horſes, and other Cattle. They uſually give it them in the Manger, ſometimes in the Field; and it anſwers very well either Way. The Cattle eat it greedily, and it anſwers both for Oats and Hay.

They uſe a particular Kind of Turnep for this Uſe, known by the Name of the yellow Turnep. The Seed of which is ſold diſtinctly from the others at every Seed Shop. They ſow it in MARCH, and the Turneps are ready to pull at the End of MAY; and they continue ſowing again and again once in ſix Weeks, for a conſtant Supply, till the latter End of SEPTEMBER; in all which Time it keeps the Cattle in excellent

Heart, and enables them to go through their Work equally to any Food whatever.

It may not be amiſs, in ſpeaking of the Management of the Horſe Kinds in theſe Counties, to obſerve a Cuſtom they have of ſpaying their Filly Foals. They do this at a Month or ſix Weeks old, while they ſuck, and it is attended with no Danger. The Mare becomes a particular, and a very uſeful Creature; ſhe grows large and very tough and ſtrong withal, ſo that, in general, ſhe is preferable to a Gelding.

The only Inconvenience theſe ſpay'd Mares are liable to is, the over-growing at the Joints, which ſometimes makes a Weakneſs in thoſe Parts; but this may be, in ſome Degree prevented, by ſpaying them when they are a little farther advanced in their Growth. A very good Time for this Purpoſe is juſt when they are taken from the Dam, when that is done at ſix Months, which is the Cuſtom in many Places, for the cutting heals while they are under the Care of the Weaner.

At the Approach of Winter it is the Cuſtom in moſt Counties, to take up the Horſes, becauſe the Graſs becomes ſhort, and the Seaſon cold: but the Condition of the Creature ought to be the Rule for this, more than the Month of the Year. So long as he can well endure the Weather, and the Food anſwers for him, he will be much better in the Field, than in the Stable: and the ſaving the Expence of Stable Food is no trifling Article.

It is a good Method alſo to moderate between the two Extreams, by taking them into a Stable at Nights, and turning them out by Day; as the Seaſon may require it.

Another more general Way of moderating the Matter may anſwer very well, in the following Manner. Let a ſufficient Number of Hovels be built in the Yard: their Shape to be a long Square, the Front and Ends open, and the farther Side boarded up; and the Top cover'd with Furze, or other cheap Stuff. Againſt the boarded Part are to be fix'd the Mangers; and the Horſes are to have Acceſs to theſe when they like. Thus they run looſe, or are under Cover as they chuſe; and when Oats are given them they feed dry: this does not make them tender like keeping them in the Stable; and is excellent for preſerving their Feet ſound, and keeping them in Health and Heart, and at all Times ready for Service.

It is not underſtood that the Horſes, in this Management, have Liberty to run any farther than about the Yard, becauſe if they had, their Dung would be loſt: whereas, in this Way, all is ſav'd, and that in the moſt beneficial Manner poſſible, and the Horſes eſcape the Confinement of the Stable, which is the Occaſion of half thoſe Diſorders that they are troubled with.

As to the Manner of feeding the Huſbandman's Horſes, in order to make them go through their hardeſt Work with Eaſe and Satisfaction both to themſelves and their Owner, the beſt Way is this.

In Winter let the Perſons who have the Care of them be up at Five o'Clock; and in Summer at Four; and let them bait their Horſes in the following Manner. Mix ſplit Beans, Bran, Oats, and Chaff; or elſe mix Oats, Bran, and Chaff only; and give them a little at a Time, dreſſing them while they are eating. Bran is a very neceſſary Ingredient on this Occaſion, becauſe it makes the Chaff go down, and ſome give it all the Year, accounting that it ſaves Corn, and does the Horſe ſufficient Service, making at the ſame Time all his other Food taſte the more agreeable.

For other Methods, half a Peck of Oats may be given in the Morning before going to Plow, and the ſame in the Afternoon: or after they have baited a little while in the Afternoon, a little Hay may be given them, and they may be led to water. This is a very good Method where a Horſe ſeems to want a right Appetite, for they never fail to eat after it freely.

Chaff mix'd with the Oats is very uſeful upon theſe Occaſions, and a little being given at a Time, the Creature eats it the more heartily and freely, and it digeſts the more perfectly.

But whatever Method be taken, let the Huſbandman be ſure that his Horſe has Food enough; for, whatever he withholds in this Reſpect, is to his own Damage. He ſuffers more by it than the Horſe, for the Creature cannot perform his Work well, nor will he be fit for Sale unleſs to a great Diſadvantage. Many a Horſe have been reduced one half of his Value, by the ſaving a very ſmall Proportion of that Charge in his Food: this is frequently in other Inſtances alſo the Effect of fooliſh Frugality. I ſhall recommend the Huſbandman in all Things to Œconomy, but let it be under the Guidance of Prudence. I have adviſed him to ſpare no Expence in manuring his Lands, becauſe the Crop will be ſure to repay it; and in the ſame Manner he may be ſure that good feeding of his Cattle will be paid him doubly, partly in their going through their Work, and partly in their Improvement for Sale.

CHAP. IX.

Of the Aſs.

THE Aſs follows the Horſe in this Place, not as the next Creature in Value, for he bears in that Reſpect no Proportion to the Horned Cattle; but it is proper to treat of him in this Order, becauſe he approaches in ſome Things to the Nature of the Horſe, and is employ'd in many of the ſame Kind of Services.

The Aſs in London is the moſt to be pity'd of all Creatures; and in many Parts of the Country he does not fare much better. He endures great Fatigue, and his Patience is as a Virtue. This is a Creature that may be made more uſeful than it generally is; and that deſerves much better Treatment than it commonly meets with.

A French Author has written a Treatiſe, to prove that the Aſs is the moſt uſeful to Man of all Animals; he founds this Aſſertion upon its doing a great deal of Buſineſs, and being kept at a very ſmall Expence. But altho' we ſhall not altogether agree with this Writer, yet

we may with Reaſon endeavour to ſet this Creature upon a more reſpectable footing with Mankind, than that wherein he uſually ſtands.

The Aſs may be purchaſed at a ſmall Price, as well as kept at a ſmall Expence, and is therefore a very uſeful Creature to ſuch as want the Labour of ſome ſuch Animal; and yet have neither Money to purchaſe a Horſe, nor Food to ſupport him.

The Aſs will not only do a great deal of Work, but he will bear all Sort of Inconveniencies in a ſurprizing Manner. He endures Fatigue, Heat, Cold, Hunger and Thirſt better than any living Creature. He is liable to very few Diſorders: is very long liv'd; and retains his Strength and Abilities for doing Service to a very great Age. All this ſhould recommend this Creature to the poorer Sort of Huſbandmen in the ſtrongeſt Manner.

He will live upon a Common be it ever ſo barren, a Whiſp of Straw is very acceptable Food: he will crop Bryars and Thiſtles; and Chaff is a Treat to him. A little more Care might very well be afforded for them than is generally allowed; and they would repay it with very large Increaſe of their Labour.

No Creature is better ſuited to carry Burthens than the Aſs: it will alſo raiſe Water in deep Wells, and work in Mills full as well as a Horſe, and will not ſtand the Owner in near the Expence of the very worſt of that Kind.

But the induſtrious and conſiderate Owner may make them anſwer many other Purpoſes. We ſee Aſſes draw Burthens of Sand in a ſorry Kind of Carts: ill-harneſſed, ill-tended, and under every poſſible Diſadvantage. No doubt but the Huſbandman who ſhould chuſe to employ them in Draught, and would give them but tolerable Tendance, would find his Account in it in many Kinds of Carriage not yet thought of for them.

There is no Queſtion but the Aſs may be made to anſwer the Purpoſe of the Horſe in Plowing; eſpecially in light Lands: and every ſaving to the Farmer being ſo much Gain, here would be a very conſiderable Profit: for the worſt Horſes muſt be fed at a conſiderable Expence to enable them to go through their Labour.

The ſhe Aſs has alſo a particular Value on Account of her Milk, which is preſcrib'd by Phyſicians for many Diſorders; and in London brings a very large Price, although thoſe who keep the Aſſes for that Purpoſe very ill deſerve it, by their Manner of feeding them.

As I have mention'd the Benefits that may attend the keeping of Aſſes, it is reaſonable alſo to name the Inconveniencies: and theſe are principally three. Their Slowneſs, their Stubbornneſs, and the Damage they are apt to do among Trees, no Creature whatſoever devouring the young Shoots ſo greedily.

As to their Slowneſs, it is a Fault they can never be expected to mend, for it is in their Nature: we are to take all Creatures with their natural Imperfections, and this is that of the Aſs: but thoſe Faults are generally attended with Advantages, as this in particular very plainly is. The Slowneſs of this Creature being the very Thing that enables him to continue ſo long at his Labour; and undergo ſuch laſting Fatigue; for if his Motion was quicker, he would tire like the Horſe, and other Animals.

As to the ſecond Charge, his Stubbornneſs and Obſtinacy, 'tis certain that it is well founded, for no Creature is ſo ridiculouſly reſtiff as an Aſs, when he is provoked beyond his Patience, which may be done; or ſometimes without Provocation. Something of this may be in Nature, as well as his Slowneſs; but a great deal of it is owing to his ill Management. No Creature is ſo little regarded, or treated with ſuch wanton Cruelty as the Aſs. He is generally put into the Hands of Boys, or the worſt of Servants, who certainly increaſe his natural Obſtinacy by their Uſage.

Let the Aſs be taken but moderate Care of; and treated a little like a Horſe, tho' it were but like the very meaneſt Kinds of the Horſe, and if he does not become altogether ſo tractable as that Creature, yet he will loſe enough of his natural Fault in this Reſpect to be render'd very uſeful; and will fully anſwer the Care that has been taken of him. This I write from my own Experience.

In the laſt Place, it is indeed likely that the Aſs ſhould crop and ſometimes bark Trees, for they are his natural Food: but it is not particular to this Animal. In the preceeding Parts of this Work we have been oblig'd to give frequent Directions for the defending young Plantations of all Kinds from the croping of Animals; from the Quickſet Hedge to the Timber Tree. The ſame Care that preſerves them from other Creatures, will, in many Caſes, keep them alſo from being damag'd by this; and where that cannot be done, the Creature muſt be kept from them.

If the Huſbandman ſhould take a Reſolution of keeping a great many Aſſes, he might, with a very little Care, keep them out of improper Places; and prevent this Miſchief.

Among other Benefits attending the keeping of this Creature, is to be reckon'd the breeding of Mules, a Thing practis'd to vaſt Advantage in many Parts of Europe, and which it is ſurprizing that we have not introduced to general Practice in England. Of this we ſhall treat at large in a ſucceeding Chapter.

As we have in ſome Manner recommended to the Huſbandman the keeping of Aſſes, we ſhall not leave the Subject without giving him Directions for their Choice.

Aſſes brought from ſome of the warmer Parts of Europe, are greatly preferable to ours in Stature, and for the breeding both of their own Kind and Mules: when we ſee one of theſe Aſſes compared with one of the wretched Creatures of our own Country, we muſt naturally allow the great Advantage of giving the Aſs proper Care and Management, for they are better look'd after in thoſe Places; and their Excellence in every Reſpect is in a great Meaſure owing to that.

Where one of theſe Aſſes can be had, doubtleſs it is to be prefer'd; but this is a particular Caſe. I ſhall ſuppoſe the Huſbandman is to

chuſe out of ſuch as our own Country naturally lays before him; and among theſe let him ſelect ſuch as are bulky, and well ſquared. Such as have large and full Eyes; wide Noſtrils; and long Necks. The Breaſt of an Aſs ſhould be broad; his Shoulders ſhould ſtand high; and he ſhould have a full Back. The Shortneſs of the Tail is alſo judg'd by many a Mark of Strength and Hardyneſs in an Aſs; and ſo far as I have had Experience to judge, I think, with Reaſon.

The beſt Colour for this Creature is dark; the nearer black they are, uſually the ſtouter they are found on Trial; and the Hair lying ſleek, is a good Sign of its being in Health and Vigour.

Let the Huſbandman who intends to ſupply himſelf with Aſſes for the proper Services, chuſe a few in this Manner, with a ſtrict Regard to their Age and Strength; and from theſe let him raiſe a Breed.

The beſt Time for covering the ſhe Aſs is in April or May: the End of March or Beginning of June will do; but earlier or later than the firſt or the laſt of theſe it ſhould not be.

The beſt Age of the Aſs for breeding is five, ſix or ſeven Years: ſhe may be uſed for this Purpoſe from three Years old to ten; but ſhe is in her greateſt Vigour, and will bring forth the fineſt Colts at about ſeven Years old.

A good ſtout he Aſs, and a large bodied ſhe ſhould be choſen for breeding; and ſhe ſhould be wrought gently toward the End of the Time ſhe is going.

Theſe are ſhort and eaſy Directions; and yet they will be found of great Uſe. The Huſbandman who will carefully obſerve them, will be ſure to find their Advantage; and if he add to this Care of breeding them, a very little tending of them when grown up, he will be able to ſhew Aſſes, if not equal to thoſe of ſome other Parts of Europe, at leaſt greatly ſuperior to thoſe commonly ſeen in England: and he will by their Means do a great Part of his common Buſineſs fully as well as with Horſes, and at a much ſmaller Expence.

CHAP. X.

Of the Mule.

AFTER the mention of the Horſe and the Aſs, naturally follows the Mule, that being a Creature produced between the two, and of a middle Nature between the one and the other.

The Mule has the good Qualities of the Aſs without its bad ones. It is as patient of Fatigue, and as capable of enduring Hunger as the Aſs; but then it is as tractable as the Horſe; and is ſufficiently ſwift of Foot for any common Service. When properly bred it is alſo a very handſome Creature: and it is indeed ſo well fitted for ſo many different Services, that nothing can be more worth while than raiſing them in all Places where they will thrive.

The Mule is often of the Size of an ordinary Horſe, ſome are ſixteen or ſeventeen Hands high. They are very ſtrong, and very ſure footed. This is the Quality for which they are valued in many Parts of Europe, where the Roads are mountainous and ſtony; they will go with the greateſt Safety over theſe, where a Horſe would break his Neck.

They perform excellently alſo in Draught; and will travel many Weeks together with ſix or ſeven hundred Weight on their Backs, without any Sign of uncommon Fatigue.

The Mule is bred from the Copulation of an Aſs and a Mare. Thoſe for Travel and Shew are bred from very large he Aſſes and Spanish Mares: theſe are tall and ſtately, their Colour uſually inclining to black, and they are very handſome. But a larger and ſtouter Kind are bred from the ſame Aſſes, and large Flanders Mares. Theſe are frequently ſeventeen Hands high, and as large ſet as our common Coach Horſes. They are much ſtronger than Horſes of the ſame Size, and will bear greater Hardſhips, and be fed at much leſs Expence. At the ſame Time they are much leſs ſubject to Diſtempers. Theſe are great Recommendations of this Creature; and may ſhew how much it would be to the Advantage of the Farmer always to have them in his Yard.

They are extreamly fit for the Saddle, as well as for theſe laborious Employments: they are very manageable, and walk and trot very eaſy. If it ſhould ever become a Cuſtom to breed them in England, they may be ſuited to the Services for which they are deſign'd, by the Choice of proper Mares, for they take after them. Thoſe for the Road ſhould be bred from light made Mares; and thoſe for Cart, Plow, and the like, from the larger bodied and ſtouter Kinds.

There is a very ſubſtantial Reaſon why we ſhould breed them in England, which is, that ſuch as are bred in colder Countries, are always better and longer lived than thoſe in hot. As to the Objection ſome have raiſed of their being vicious, it is a Complaint only made where there are but few of them, and thoſe ill taken Care of; for where they are common, and are treated in the ſame Manner as Horſes, they are as inoffenſive.

Beſide the Mule already mention'd, which is bred between the Aſs and the Mare, and is a light, beautiful, and lively Creature; there is another Kind propagated in ſome Places, raiſed between the Horſe and the ſhe Aſs; but this is an inferior Kind.

It has been obſerv'd, that Foals take more after the Nature of the Female than the Male Parent; and the ſame Thing is ſeen very plainly in the Breed of Mules: thoſe between the Aſs and the Mare, partaking of the Nature of the Mare, being beautiful, lively and ſwift; and only inheriting the good Qualities of the Aſs, his Patience, Strength, and Perſeverance under Fatigue: while on the contrary, thoſe bred from a Horſe and a ſhe Aſs, are of the Aſs Kind, dull, heavy, ſluggiſh, ill-made, and ſmall. There is very little Temptation to breed theſe any where, becauſe the others may be had with as little Trouble. Let the Huſbandman

therefore who ſhall think of breeding Mules among his Stock, take Care that he does not fall into the Miſtake of ſuppoſing that 'tis the ſame Thing, ſo one Parent be of the Aſs Kind, which of the two it is: he here ſees the Difference.

As the Mare is to be ſuited to the Service for which the Mule is intended, great Care is to be taken to have a proper Aſs. He ſhould have all the Marks of a good one deliver'd in the preceeding Chapter, and above all Things he muſt be large. The fine Mules we ſee in other Parts of EUROPE are bred from the talleſt Aſſes that can be procured; which they purchaſe at a vaſt Price, and of their fineſt Mares. The Mare is put into a hollow Place rail'd in, and the Aſs has the Advantage of higher Ground in covering.

We ſee in this Circumſtance of the Mule, the Abhorrence of Nature to Monſters, or Animals produced of mix'd Breeds. It was believ'd among the Antients, that new Sorts of Savage Creatures were every Year produced in AFRICA, from the Copulation of different Kinds, and the Increaſe of thoſe Monſters ſo produced; but this is an Error; and we ſee in the Inſtance of the Mule, that two Creatures of a different, though like Kind, are very difficultly brought to copulate; and that when they are, altho' they produce a Creature different from either, as the Mule is both from the Horſe and Aſs, yet that Creature is not able to propagate its Kind again.

The Pretence that there is any where a Sort of Mules that produce their own Kind one among another, is as falſe as the new Species of Monſters in AFRICA. The Horſe and Aſs are difficultly got together, in order to the Production of this Animal; but when that is done, there is no carrying the Power any farther.

The Mare is always averſe to receive the Aſs, and in the ſame Manner the ſhe Aſs is unwilling to admit the Horſe to Copulation; inſomuch that where they breed Mules frequently, it is a Practice to make the Aſs colt ſuck a Mare: and the Mare foal ſuck an Aſs, in order, as is imagin'd, to make them in ſome Degree partake of the Nature of either. This has no real Effect, but I have named it to ſhew how ſenſible the Breeders of Mules are, that thoſe Creatures do not go freely and willingly together: and it is certain, that there is not in Nature any Power of the Mules generating its own Kind again.

CHAP. XI.

Of the Bull, and his Kind.

UNDER this general Head are included, the Bull, Cow, Ox, and Calf, each of them a very conſiderable Article in the Huſbandman's Profeſſion; and though all of one Kind, yet for Clearneſs ſake, to be treated of ſeparately and diſtinctly. The Cow is naturally conſider'd as the principal, though the Female, becauſe ſhe is the moſt univerſally uſeful to the Farmer; but before we enter upon her Nature and Qualities, we ſhall treat of the Bull in his natural Condition, and in that of the Ox; as a Knowledge of them will beſt lead to the other.

In other Countries there are Bulls of ſeveral Kinds and Forms, under the Name of Buffaloes, and the like Diſtinctions: but in ENGLAND we have properly only one Kind.

The Bulls of ENGLAND, however, tho' they are of the ſame in Kind, differ in their Size, and other leſſer Circumſtances, according to the Counties from whence they come, or in which they are bred. The different Parts of this Kingdom afford ſo different Paſturage and Support for Cattle, that they are eſtabliſh'd in them under certain Diſtinctions; and when they are brought into others, are called after the Name of the Place whence they came. Thus the LANCASHIRE breed is large, the WELCH are ſmaller, and the SCOTCH leaſt of all. In STAFFORDSHIRE they are commonly black, and in GLOUCESTERSHIRE red; and they have the like Differences in other Counties.

The Huſbandman who is about to ſtock his Farm, ſhould be acquainted in general with the ſeveral Breeds, that he may be able to ſuit his Purchaſe to his Land.

The larger and finer Kinds are bred where there is good Nouriſhment, and they require the ſame wherever they are kept, or they will decline: and, on the other hand, the poorer and ſmaller Kinds which are uſed to hard Fare, will thrive and fatten upon a moderate Land, becauſe it is richer than what was naturally their own.

The Huſbandman will do well to remember here what we have laid down concerning Trees, that they never thrive if tranſplanted out of a rich into a poor Soil; and the ſame holds good in Cattle: let him never remove them from rich Lands to poor ones.

Every Huſbandman ought to have one of theſe three Conſiderations principally in View, in ſtocking his Land with this Kind, the uſing them principally for Breed, for Milk, or for Work; and according to which of theſe three is his principal Aim, he is to make his Purchaſe: one Breed being fitter for one of theſe Uſes, and another for another.

He is alſo to conſider the Degree of Richneſs of his Paſtures, that he may ſuit the Breed accordingly to that alſo. Thus if his Ground be perfectly rich, he ſhould buy the largeſt and fineſt Cattle, the DERBYSHIRE, STAFFORDSHIRE or LANCASHIRE Kind; if poorer he ſhould purchaſe the ANGLESEA or WELCH, for they will thrive and fatten upon very moderate Ground: and in the ſame Manner he ſhould ſuit his Cattle to the Nature and Qualities of his Paſture, be they whatſoever they will.

Whatever Breed the Huſbandman chuſes, he is to take Care that he keep entirely to it; that is, the Bull and Cows are to be all of the ſame Kind; for it is a general and very true Obſervation, that a mix'd Race does not ſucceed ſo well in any Place, as where they are all of a Sort.

Having premis'd thus much of the ſeveral Breeds of theſe Cattle, on which Head we ſhall

enlarge farther under the Conſideration of each particular Kind in the ſucceeding Chapters, we ſhall here proceed to ſpeak of the Bull in general: not as of any particular Kind, but of whatever; for the Marks of a good Bull, are the ſame in general in all the Breeds.

In the Choice of his Bull let the Huſbandman guide himſelf according to the following Directions. Let his Forehead be broad, and the Hair upon it well frizzled and turn'd in ſmall Curls. Let his Countenance be ſharp, his Eyes large and full, the blacker the better. Let his Horns be moderately long. His Neck thick and fleſhy; and his Body long and large. His Breaſt ſhould be big, his Back ſtrait and flat, his Buttocks large and ſquare, and his Thighs round. His Legs ſhould be ſtrait, his Joints ſhort, and his Hair ſhould lie ſmooth and even upon his Body. This Sort of Bull anſwers the beſt in every Reſpect for Breed. The Oxen from him are always inclin'd to be large and ſtout; and are fit for draught as well as feeding.

Thoſe who are very curious in their Breed, obſerve that the Ears of the Bull be rough within, that his Noſtrils be wide, and his Dewlap thin, long and hairy; that his Tail ſtand high, his Knees be large and round, and his Hoofs long and hollow. Theſe are Marks of leſs Conſequence, tho' ſome ſtand upon them with great Strictneſs: a very good Bull may be without them; or without any Thing particular in any of theſe Parts; but if he anſwer the Deſcription in all Points it is ſo much the better. The others before deliver'd are, however, of great Conſequence, and the Huſbandman's Intereſt requires him to obſerve them ſo ſtrictly, that he ſhould never admit a Bull among his Cattle, that does not anſwer to them.

The Breed in this, as in moſt other Kinds, partake more of the Nature of the Female than the Male; yet there is ſo much depends upon the Male, eſpecially in the Form of the Ox, and moſt particularly when they breed that Creature to labour; that the Owner can never be too particular in his Examination of the Bull, which is to be the Father of his Breed.

The Uſe of the Bull is commonly underſtood to be only in the Service of the Cows in Propagation; and accordingly in moſt Places, he is ſuffer'd to run looſe, living a quiet Life, with no Care but his Pleaſures. This, however, is not neceſſary. The Bull is an Animal of Strength as well as the Ox, and there is no Reaſon why he ſhould not be employ'd in the ſame Manner. This is not univerſally practis'd, but by an Account we have receiv'd from a very worthy Correſpondent on theſe Subjects, who writes nothing but what he has try'd, it is very plain that it may be introduced any where with Advantage. I ſhall here inſert his Letter as it lies before me, in his own Words, and without Addition or Deviation.

To ****.

" Whereas you have deſir'd me to let you " know any Thing that ſhould fall in my Way in " the Courſe of Huſbandry not commonly prac- " tiſed, I take this Opportunity of acquainting " you with a Uſe I have found for my Bulls.

" You know it has always been my Prac- " tice to raiſe more of this Kind than others do " with ſuch a Stock as mine; but I fancy they " generally don't allow Bulls enough to their " Cows, and that the Breed ſuffers by it. How- " ſoever that be, I keep a larger Number, and " feeding them ſeparate, I ſeldom have any " Miſchief among them. But it came into my " Thoughts that I might as well have ſome " good of them beſide juſt the Breed, and not " keep ſo many large Creatures only for that " Service. Upon this I began to think of ſet- " ting one of my ſtouteſt Bulls to labour.

" You are ſenſible that this is not a County " any more than yours, where they put their " Oxen to draught: ſo whether or no they uſe " the Bulls in thoſe Places for the ſame Work, " I can't tell: but by what I hear, I believe " not.

" I try'd one of my ſtrongeſt Bulls firſt at " Cart. We had ſome large Timber to carry, " and I made them put the Bull to the Car- " riage that we uſed. He was a little ſtubborn " at firſt, but after four or five Trials he would " draw very well. I find him ſlow but very " ſtrong, and he anſwers exceedingly.

" I uſe him not only in the Carriage of Tim- " ber; but in drawing the Clay from the Nor- " field Pit, to the ſandy Piece you adviſed me " to dreſs with it, and he will pull a vaſt Load " with Eaſe.

" I have try'd to put a Couple of them to a " Cart together, but they do no better than one, " for they will never draw equally. One pulls " all, and the other lags, or walks eaſy. I have " alſo try'd to yoke them for plowing, but it " does not do. But the firſt Bull that I broke to " drawing, works very willingly at Plow alone, " and I have turn'd up my heavieſt Soils with " him.

" You ſee I write freely what can be done, " and what cannot, ſo far as my ſmall Practice " informs me; I have computed all Things, " and am convinced that it would be very much " to the Advantage of Huſbandry, if Bulls " were made to work every where. I have " been able yet only to make them draw ſingly, " but perhaps others upon more Trial, may " bring them to go together.

I am,

Your humble Servant,

R. G.

It is needleſs I ſhould add any Remarks on this plain Letter. It is in every ones Power to try whether Bulls Labour anſwers according to this Account; and, if ſo, it will be worth while to try how far they may be brought to work together: not that in this Caſe they are of equal Value with the Ox, who, beſide his Labour, has his Fleſh for Market; but there is no Reaſon any Part of the Huſbandman's Stock ſhould lie idle. The Bull feeds, and he ought to work. Being properly employ'd he will not be at all the leſs fit for his Buſineſs in propagating the Species: rather the fitter.

The Diverſion of running and baiting the Bull at certain Times of the Year is very old, and has

has been practiſed in many Parts of the World, and in moſt of them at the ſame Seaſon. We ſeem to have had it from the SPANIARDS, whoſe Bull fights are famous; and they from the ROMANS, as the ROMANS had it from the GREEKS. JULIUS CÆSAR brought it to ROME, and he profeſſedly learned it of the THESSALIANS. In GREECE, ROME, SPAIN and ENGLAND, the Seaſon for it has always been in the Month of AUGUST.

The Bull is often miſchievous; but it is in a great Meaſure owing to his being kept idle. Many a Life is loſt in ENGLAND by this Creature: but probably if it ſhould ever become a Cuſtom to train them to labour like other Animals, there would be an End of that Miſchief. The Bull is the only Creature of ſuch Size and Power that is left to himſelf. If he were worked, partly the Labour, and partly the being accuſtomed to Mankind by their tending of him, would tame him, and make him as harmleſs as Horſes and other Animals. They are often naturally vicious as well as the Bull; but it is their being continually in the Way of Management that breaks them.

CHAP. XII.

Of the Ox.

THE Naturaliſt would ſmile at our treating of the Bull in one Chapter, and the Ox in another; but we know as well as he they are the ſame Creature under different Accidents. Their Uſe to the Huſbandman is, however, ſo different, that in a Work of this Kind we are very well juſtified in treating of them in this ſeparate Manner.

If the Huſbandman's Land be rich, let him ſtock it with the largeſt Oxen that can be rais'd, for they are much the moſt profitable.

The YORKSHIRE Oxen are in general, black all over, and they are very large, firm and valuable Kind in every Reſpect. There are none that exceed them for Labour, and few feed like them. The Oxen of STAFFORDSHIRE, and many of the neighbouring Counties, are alſo of this Kind. The Oxen of LINCOLNSHIRE are in general red and white: they are very bulky, and equal to any in Value. The Oxen of SOMERSETSHIRE, and ſome of the adjoining Counties, are naturally red. Theſe are alſo a very fine, large, and valuable Breed.

If the Huſbandman intend to breed his Oxen to Draught and Labour, the black YORKSHIRE Breed is the beſt: if for Market only, LINCOLNSHIRE are preferable: the red SOMERSETSHIRE Ox is indifferent to either Uſe, and is an excellent Kind.

Of all theſe the LINCOLNSHIRE Breed require the richeſt Paſture: but none of them will thrive, or come to their Perfection, unleſs they have very good feeding.

The Reader is not to ſuppoſe from what is here ſaid, that all the Oxen of YORKSHIRE are black, all thoſe of GLOUCESTERSHIRE and SOMERSETSHIRE red, or all the LINCOLNSHIRE Oxen pyed.

Theſe are the genuine and proper Breed of each of thoſe ſeveral Counties; but the Graziers have mix'd them more or leſs in each County, though 'tis beſt both for Beauty and Service to keep them ſeparate: their Kinds and Diſpoſitions being in each Particular, as well as the Colour.

The Huſbandman who intends to ſtock his Land with either of theſe Kinds, muſt at firſt buy, but he is afterwards to breed; and in order to keep up the Sort with Certainty, he muſt take Care to have a right Bull, and well ſized Cows, both of the ſame Breed; and from this Stock, with a Sufficiency of Paſturage rich enough for their Support, he will not fail to have either Breed in any County: perhaps better than they are to be found in the Places themſelves, as they do not take due Care there, but bring in one Kind among another.

The Oxen ſhould be tall, full bodied, ſhort jointed, and well put together in every Part, ſo that one ſees their Strength. Their Hair ſhould be fine, and lie ſmooth, for that betokens Health, and a good Kind.

The Strength of the Ox is very great, and he has Patience to endure Fatigue, but he is ſlow, and muſt not be put beyond his natural Pace. He will not work eaſily or freely, if this be attempted, and what is worſe, fretting and hurrying throws him into Diſtempers.

'Tis but in ſome particular Parts of ENGLAND they now breed their Oxen to Labour, but it is very profitable. In theſe Places the Huſbandman cannot be too much warn'd againſt his hurrying them in their Employments; for he ſhould conſider that they are to be fed as well as work'd; and while he makes them thus liable to Diſtempers, he takes them off from the one, and makes them incapable of the other.

When Oxen are to be train'd to labour, they muſt be firſt put to work at three Years old, but they muſt be brought to it gently, and, by Degrees, in the Manner of a young Horſe; for if they be puſh'd or work'd too hard at this Time, they are ſpoil'd for ever.

Great Care muſt be taken to match ſuch well as are to draw together, for otherwiſe they draw unequally, and ſpoil both the Work and one another.

In this Caſe of matching them, Regard muſt be had to three Things; their Height, their Strength, and their Spirit: for ſome are tall that have not much Strength; and others have a great deal of Power that are ſluggiſh.

In general they are very tractable and gentle, but regard muſt be had to their ſeveral Natures, for they will not be forced out of them by any Uſage; and they may be greatly injur'd in the Endeavour.

Of all the Kinds the pyed LINCOLNSHIRE Ox is the fitteſt for Labour. He is naturally long bodied, and till put up to feed, is leſs fleſhy than any of the other good Breeds; tho' he takes to fattening very readily with Reſt, and a good Paſture.

When the young Oxen are firſt put to work, a great deal of Care muſt be taken not to over-heat or fatigue them. They muſt be ſuffer'd to reſt in the Middle of the Day in hot Weather,

Weather, and the Servant ſhould give them ſome Hay, which will ſupport them in the new Fatigue of their Labour, much better than Graſs. They muſt be well fed during the whole Time of their labouring, for they will not do much if they be not kept in Spirits by good Nouriſhment; but in this let the Huſbandman underſtand Moderation: for there is Difference between feeding them for Strength, and for fattening.

An Ox for Labour muſt neither be bare, nor muſt he be too fat; in the firſt Caſe he will be weak, and in the other he will be lazy. They ſhould be treated gently, for they do not underſtand Blows and hard Uſage, and may eaſier be beaten into Sickneſſes and Diſorders, than into Labour.

In this Way an Ox may very well be kept to work ſeven or eight Years, that is, till between ten and eleven Years old; and in that Time he will do the Owner an incredible deal of Buſineſs, provided he thus underſtand how to manage him, for it all depends upon that; otherwiſe he will be as ſtubborn as an Aſs, and will not be fit half his Time for Service.

Sometimes a young Ox will prove very ſtubborn, vicious and unruly; but this, when enquir'd into, will be found owing to ſome bad Uſage at ſetting out, for the Ox has nothing of that bad Diſpoſition in his Nature. When this happens he muſt be kept hungry; and when he has faſted long enough, he muſt be made to eat out of the Hand: when he is brought to his Labour, he muſt be tied with a Rope; and at any Time when he grows faulty, he muſt be cheriſh'd, and fed with a mouthful of Hay by hand; thus bringing him by ſoft Means to Quietneſs, and a Readineſs in performing his Buſineſs; for nothing elſe will do with this Creature.

For the breaking a young Ox to the Field, no Way is ſo well as to ſingle out one of the tameſt of the old ones, that is of its own Size; and yoke them together. Let them be put to ſome ſlight Work, and ſuffer'd to do it eaſily and ſlowly: they will thus draw equally, and the young Beaſt will become perfectly familiar to it. They will be apt to get into too ſlow a Gait at firſt, but by Degrees they muſt be ſpirited to be a little briſker in their Pace; and after half a dozen Times going out with this quiet Beaſt, the young one muſt be coupled with an Ox of more Spirit, that will learn him to go quicker. Thus he is to have his Companion chang'd from time to time, till in the firſt Month or ſix Weeks of his Labour, he gets to draw with the briſkeſt of the Stock.

This is the only Way to get the Ox to his Speed; for at beſt it is not great, nor will he be brought to it by force.

The Advantages of labouring with Oxen are ſo great, that it is wonderful the Practice does not extend farther. The Ox of eleven Years old, when he is unfit for Labour any longer, may be fatten'd as well as at any other Time; and in the ſame Manner if he fall lame, or by any other Accident be ſpoil'd for Labour, at whatever Age that happen, he may then be fed up for Sale.

In this the Ox has a great Advantage over the Horſe, which, when aged, or ſpoiled by Accidents, is good for nothing, and becomes an entire Loſs, and often a very great one to the Farmer.

The Food of the Horſe is alſo a very expenſive Article to the Huſbandman, but that of Oxen is cheap. They require no Oats. They are very little liable to Diſeaſes, whereas one is never ſecure of a Horſe at all. But though the Ox does not require ſo expenſive Food as the Horſe, yet ſuch as he eats muſt be good in its Kind, and he muſt not be ſtinted. He muſt always have good Graſs to go to, and good Hay in Winter, elſe he will be of little Service: for though he muſt not be fatten'd in his Time of working, yet if he be not kept well fed, and in good Spirits, he is worth nothing.

The greateſt Uſe of the Ox in the Way of Labour, is that of Plowing; and 'tis that for which they are ſuited by Nature. They will work at this in the toughеſt and heavieſt Grounds as well as Horſes, and do as much in a Day. They do not ſerve ſo well for drawing of Carts and Waggons; and are not fit to be uſed much in Places where the Roads are good.

In moſt Counties the Farmer would do well to train up ſome of his Oxen for Draught, tho' it is better not to depend upon them entirely for that Service, in any. We have ſhewn for what they are moſt, and for what they are leaſt fitted. Every Farmer has Occaſion both for Carting and Plowing; and the Horſes are in general fitteſt for the former, and the Oxen moſt profitable for the latter: therefore when there are more Teams than one kept, ſome ſhould be of Horſes, and others of Oxen, proportioning the Number of either to the Nature of the Service, and of the Roads and the Ground. The Farmer who keeps two Teams only, will almoſt always find it his Intereſt to have one of them of Oxen, and the other of Horſes.

In clayey Lands, the Oxen are moſt uſeful; and in chalky Countries the leaſt. The Chalk ſoon ſpoiling their Feet.

It is a Cuſtom in ſome Places where Oxen are uſed for Draught, to yoke them by the Horns, but this is awkward and troubleſome. It is left off in many Places where it was once uſed; and ought to be in all. The common Way of yoaking them together by the Neck and Breaſt is vaſtly preferable.

Whenever the Farmer comes to a Reſolution of keeping Oxen for Labour, let him at the ſame Time provide for a proper Supply of them; and ſee that it be rather too much than too little, for it will always be more to his Profit to ſell what he does not want, than to buy for his neceſſary Uſes. To this End he ſhould rear at leaſt two Oxen and two Cow Calves every Year to keep up his Stock; and put his old, or injur'd Beaſts to fatten, and ſupply their Places from this Breed as Occaſion requires: for an Ox, as before ſaid, whether put out of the Team for Age or Injuries, will fatten as well as at any other Time, and will bring a good Price at Market; and afford as good Beef as any other that had not been work'd.

When the Huſbandman buys in Cattle to fat-

ten, it ſhould be either in Spring, or toward the Beginning of OCTOBER. Thoſe Oxen which are bought in early in Spring well, with proper Care, be fat in JULY, AUGUST, or SEPTEMBER, according to the Goodneſs of the Soil, and the Manner of feeding them; and according to the Condition wherein they were bought. An Ox that is very forward when bought in, and is turned into a very rich Paſture, will be fit for Market in ten Weeks; but there is no need that every Ox that is bought for this Purpoſe, ſhould be in this forward Way; or that every one ſhould be haſten'd to a Market Condition in that Hurry. The Care of the Huſbandman in this ſhould be, to ſuit his Endeavours to the Nature of his Grounds, and to the beſt Demand for the Cattle: he may keep on fattening the whole Summer Months, and anſwer his Purpoſe better both for the Market, and for having the beſt Service out of his Land, than if he haſten'd up all that he bought, or bought only very forward ones.

Thoſe Oxen that are bought in about the Beginning of OCTOBER, will in general be fit for Sale early in the following Spring. There requires ſome Management in this Article of the Huſbandman's Buſineſs, for without it he may loſe by his Induſtry, but with due Care he will find a ſufficient Profit in this Way. Theſe Cattle being for Sale early in Spring, will always fetch a good Price; but the Winter feeding of them may eaſily run away with what ſhould be his Profit.

The Method is to forward theſe in Fleſh, before the Winter ſets in hard; and then to take Care only to keep them up in Fleſh during the hard Time, with Hay or Turneps.

They may be thus kept in a Condition for Market whenever it is worth while to ſell them; and be ſure of fattening up with great Eaſe very early in Spring, to a certain Advantage.

Another Way of buying Cattle in the Beginning of OCTOBER, to great Advantage, is to purchaſe lean young Oxen which will pay for their Winter Keeping by their Growth, and be ready to fatten up early in Spring, to the faireſt and fulleſt Profit.

Another very good Time of buying Oxen for feeding is in AUGUST, or the Beginning of SEPTEMBER. Theſe ſhould be got forward as ſoon as may be, by putting them into very rich Paſtures; and they will be ready for the Winter Sale.

This is the beſt Method the Huſbandman can take, who has rich and fine Paſture Ground; for no other will ſupport the large and valuable Breed of theſe Oxen. But he who happens not to have this Advantage, is not altogether to decline thus much of the grazing Buſineſs, which to the other proves ſo very advantageous.

Therefore he who has but moderately good Paſturage, and is inclined to deal this Way, ſhould ſet about in a different Manner. Let him buy in a Number of young WELCH Heifers, inſtead of Oxen, in AUGUST or SEPTEMBER, and put them into the beſt of his ordinary Paſturages. He is to take his Chance whether theſe prove with Calf or not, but either Way they will anſwer his Purpoſe.

If they prove with Calf his Buſineſs is to keep them till Spring, and then he will ſell them to a good Advantage, with a Calf by their Side, for the Dairy. If they do not prove with Calf they will preſently begin to fatten upon his Ground, which, though poor, is yet very fine in Compariſon of what they have been uſed to; and he will be able to ſell them out at a very good Account at CHRISTMAS or in Spring; at both which Times Meat is dear, and conſequently Cattle fetch a Price.

Theſe Heifers will, to the Huſbandman thus ſituated, anſwer, in ſome Meaſure, the Purpoſes of Oxen; and he is not to complain they do not bring altogether ſuch a Price; becauſe neither the Cattle themſelves, nor their Keeping, have coſt him ſo much as in the other Inſtance. Such Land being cheaper than the rich and fine Paſture Ground, on which the large Oxen may be fattened.

But there is this to be conſider'd, that the Advantage will be the greater, in proportion as the Farmer has the Convenience of Hay, or Turneps, which are the two Foods for Winter fattening of Cattle; and in Proportion to his Nearneſs to ſome large City, where the Demand and the Price will anſwer to the expenſive Feeding of Hay. About great Towns they may afford to let a Beaſt eat a Couple of Load of Hay in a Winter, becauſe the Demand is certain, and the Price good: but this will not do in remote Places.

Let the Huſbandman who buys Cattle for fattening, take great Care in the Choice, for on that will depend a large Share of his Succeſs. Let him examine their Bulk and Shape, and the Forwardneſs they are in at the Time, and after that proportion the Goodneſs of the Paſture to their Kind.

Thoſe that are intended to be kept up for a Winter, or early Spring Market, muſt be turn'd out in SEPTEMBER into the Rowens, till the Weather become ſevere by much Snow or a very hard Froſt; and till this Time they will not need any Fodder.

Upon the coming in of the hard Weather they muſt have ſome Hay regularly every Morning and Evening, which muſt be proportioned to what the Ground ſtill affords. The more they find there the leſs they want of the Supply; and the leſs there is, the more Hay muſt be each Time given them.

The Froſts have an Effect upon Graſs, eſpecially upon the worſt Sorts, to ſweeten it. The ſower Graſs which the Cattle had left untouch'd for a great while, becomes palatable to them after two or three Nights good Froſt, with a large white Ryme. They will eat this greedily; and it will make Hay the leſs neceſſary, till the Snow covers it, and they cannot get at it. 'Tis at theſe Times the foddering is to be largeſt and beſt, for without a due Care they will, in a little Time, loſe all the Advantage they had made in many Weeks.

For thoſe Oxen that were bought in lean, and are not got into any great Degree of Fleſh by the Beginning of the hard Seaſon, Straw will do inſtead of Hay: and the Huſbandman muſt begin with Barley Straw, and then come to Oat Straw, both which are very good Food to Cattle in this Condition; and will keep them as they

are, and in a Readineſs for any farther Improvement, when it comes upon eaſy Terms.

Toward the End of Winter the whole Product of the Ground that has been thus fed, will be eaten up, and then the Oxen are to be taken into the Yard. If the Huſbandman have Oxen in two Conditions, the one that he feeds with Hay, and the other with Straw, they muſt be put up ſeparate; and their Food muſt be put in Racks for them.

The Farmer often complains that his Cattle will not eat their Fodder, when they are taken up into the Yard, though they did freely when it was given them in the Field. But this is generally owing to the Folly of giving them too much at a Time. I have often ſeen an Ox eat heartily and freely out of the Crib for a Time, till when he had often breath'd upon it, what was left became quite diſagreeable to him.

This is a Delicacy in the Nature of the Animal, and nothing can break him of it; but all the Inconvenience of it is eaſily prevented, by giving theſe Cattle a little at a Time, and often. This being, for all Reaſons, the beſt Way of foddering all Cattle in the Yard.

Let the Huſbandman take Care that his Yard be well ſhelter'd, and kept dry. Let there be Straw enough ſcattered about it, that his Cattle may lie ſweet and warm, this will greatly aſſiſt in keeping them in good Caſe; and he need not grudge the Expence, for what the Straw is worth will be many Times over made up to him in Dung. Their trampling this Litter, with their Dung and Urine, converts the whole into a very rich Manure; and the Quantity becomes ſo conſiderable, that it is an Article of great Conſequence.

When Oxen are put to be fattened on Land, they may be turned in either alone or with Horſes; or they may be put into the Paſtures firſt, and the Horſes afterwards. Which ever Way is uſed let the Huſbandman take Care of the Time of turning in his Oxen. Many think they ought to let the Graſs be very well grown before they put them to feed upon it; but they are greatly miſtaken. There is not a greater Diſadvantage the Farmer can lie under, in this Way, than the having his Paſtures too high grown before he puts the Beaſts into them.

The Ox is a nice Creature, and does not love a rank Graſs. In this Caſe they only nip the Tops, and the Remainder rots upon the Ground. When Graſs is grown too high, in Autumn eſpecially, it becomes ſower, and the Cattle will not eat it freely before the Froſt has ſweeten'd it to their Taſte.

If it happen the Farmer have at this Seaſon of the Year, a Paſture Ground of tall Graſs, the beſt Method he can follow is this. Let him firſt turn in his Oxen in a proper Number, and they will eat off the Tops; but as they will meddle with no more of it, when this is done they ſhould be removed out of it. Horſes are then to be turned in, who, not being ſo nice as the Ox, will eat it down lower; and after theſe he may feed it with Sheep, which will ſtill find a great deal for their Purpoſe, that the Ox and the Horſe had both left.

If the Paſtures in the Farmer's Grounds be all of nearly the ſame Kind, and all of a proper Graſs for feeding of his Oxen, ſtill let him frequently change their Place, removing them from one of the Cloſes to another. This anſwers a double Purpoſe, it gives the Cattle a Variety of Food; and it gives every Piece of the Ground Reſt at Times to ſhoot afreſh after their eating. Their Taſte is ſo nice as to diſtinguiſh the Growth where it appears to our Eye all the ſame; and therefore they will be pleaſed with removing from one Ground to another: and each Cloſe will ſhoot up with Spirit and Freſhneſs from their cropping of it, when it is quiet for a little Time from the treading of their Feet.

Let the Huſbandman always purchaſe as large a Breed as his Ground will maintain; and by this Management he will find it ſupport a better Sort than perhaps he might imagine it could, or than it in Reality would do in the Hands of a leſs ſkilful Perſon. The Size of the Ox is a vaſt Article, for it makes great Addition both in the Fleſh and Tallow.

Let the Ox have a ſmooth Forehead and a deep Belly, if he be intended for fattening. The Strength of his Joints is more the Matter when he is firſt deſigned for Labour.

In buying Oxen for fattening Preference is to be given to the young; but if they be ſomewhat older let the Farmer ſee that they are healthful. Let him feed up his own Breed for Slaughter, if he uſes their Labour till the beſt Time of their working is over, as before directed; but let him not bring them in for fattening at that Age, without he bargain accordingly.

It is always a good Sign of Health that an Ox frequently licks himſelf. It is a Proof that he is in good Humour with himſelf, and in Spirit; for when they grow ſickly, dull, and droniſh, they utterly neglect themſelves, and their Coat becomes rough, and ſtares for want of this little Care of their own, which keeps it in order.

Nevertheleſs, every thing is to be underſtood within the Bounds of Moderation. This licking of himſelf, which is in general a Sign of Health in the Ox, may be a Diſeaſe. They will ſometimes lick till they cannot eat, for they ſwallow a great many of the Hairs they lick off, and they will ſometimes get together into a Kind of Ball in the Stomach, which will impair the Creature's Health. In this Caſe the Owner muſt, at Times, waſh the Ox with a ſtrong Decoction of Wormwood, which is a Taſte it abhors; and finding this Bitterneſs on the Skin, it will be cur'd of licking; as Children are wean'd by rubbing the Nipple with Aloes.

Some, for this Purpoſe, cover the Creature with his own Dung, but this is a filthy Way. As the licking is always done for the Sake of Cleanlineſs, the Ox will often tire himſelf, from Day to Day, with endeavouring to get this off; or elſe he will utterly neglect himſelf, which will prove of as bad Conſequence.

I am a great Friend to the eaſy and cheap Practices of the common Farmers, but they are not always right. This is often hurtful.

In examining how the Ox proceeds in fattening, the ſureſt Way is to feel the hindermoſt Rib. If all be ſoft and looſe about that, 'tis a Proof that the Creature is getting into good Fleſh. The Part behind the Shoulders in an Ox, and the

the Navel of a Cow, are the Parts to be examined, to know how they encreaſe in Tallow.

Finally, there is one Thing I ſhall recommend to the Huſbandman very ſtrongly, from my own Experience, as excellent toward the fattening of Cattle, and this is the bleeding of them at proper Times. This ſhould be done once at leaſt, and commonly it may be done twice with great Benefit during their feeding.

The Method I have always obſerved is this in the Cattle I have bought, in Spring always to bleed them as ſoon as I put them to Paſture, which makes them take to fattening directly. In thoſe I buy in Autumn I follow the ſame Method of bleeding, at the Time of turning into good Paſture; which I find not only help their fattening, but prevent Diſorders. This is all I do with thoſe intended for the Winter Market; but for ſuch as were bought lean to be kept for growing in Winter, and fattened up in Spring, I always have them blooded twice, once when they are bought in, and a ſecond Time early in Spring, when they are going into the Paſture for fattening.

My Neighbours allow that my Beaſts are leſs liable to Sickneſſes than any about the Place; and I attribute it to nothing ſo much as theſe Bleedings; notwithſtanding that ſomething is to be allowed for the Care I take in other Articles, which is greater than moſt others.

For thoſe Cattle which I buy in, lean in Autumn, for the Spring Market, I always mix Straw with the Hay I give them, by way of Fodder. I find Barley Straw does better for this Uſe than any other; and the Quantity I allow is one third Part of the whole. This anſwers for thoſe Beaſts full as well as Hay alone, and in the Affairs of Huſbandry every little ſaving is to be regarded; for all comes to ſomething.

CHAP. XIII.

Of the Cow.

WE have occaſionally mentioned the Cow in treating of the Ox, as ſometimes it is convenient to breed her in the Place of that Kind; but we now come to conſider her in another Light, in which ſhe is the moſt valuable and uſeful Part of the Farmer's Stock; this is as a Milch Cow, and with her Calf.

The ſeveral Products made from her Milk will come to be conſidered hereafter in their Place. At preſent we are to treat of the Creature herſelf, for we are, in this Place, ſpeaking of the Huſbandman's ſtocking of his Farm; not entering into every Article that may be produced from the ſeveral Kinds, of which properly hereafter.

The Cow being chiefly intended for the Service of the Dairy, a great deal of Care is to be taken in the purchaſing a right Kind, for there is a vaſt Difference in the Profit of this Animal, according to the Breed from which ſhe comes.

They have large Cows in all thoſe Counties where they breed the large Oxen, mentioned in the former Chapter, but the Size is not all that the Huſbandman is to conſider: the Quantity of Milk is not always proportioned to the Bigneſs of the Beaſt; and that is to be his chief Regard.

The WELCH and SCOTCH Cows will do upon the pooreſt Paſtures. They will ſuit ſome who cannot riſe to the Price of the better Kinds; and they will yield a very good Quantity of Milk if rightly managed; but the fine Kinds are the DUTCH and ALDERNEY Cows, theſe are very like one another in Shape, and in their Goodneſs, but the ALDERNEY Cow is preferable, becauſe ſhe is hardier.

The fine DUTCH Breed have long Legs, ſhort Horns, and a full Body. They are to be had in KENT and SUSSEX, and ſome other Places where they are ſtill carefully kept up without Mixture in Colour, and where they will yield two Gallons at a milking: but in order to this they require great Attendance, and the beſt of Food.

The ALDERNEY Cow is like the DUTCH in the Shortneſs of her Horns, but ſhe is ſomewhat ſtronger built, and is not quite ſo tender. She requires rich feeding; but is not liable to ſo many Accidents as the other, and is equal to her in the Quantity and natural Goodneſs of her Milk.

Of which ever Kind the Huſbandman determines to have his Cows, let him take the following Rules for his Direction in their Choice. Let them have the Forehead broad and open; the Eyes large and full, and, excepting only the DUTCH and ALDERNEY Breeds, which are naturally ſhort horned, let the Horns be large, clean, and fair.

They have, in ſome Parts of BUCKINGHAMSHIRE alſo, a Kind that have no Horns, they call theſe the polled Breed. They are to be choſen principally by the Breadth of the Forehead; for their Eyes are leſs full by Nature, than thoſe of many of the other Kinds.

Of whatever Breed your Cow be let her Neck be long and thin; her Belly deep and large. Let her Thighs be thick, her Legs round and well-ſhaped, and her Feet large. Above all Things ſee that ſhe have a large, good, white, and clean looking Udder, with four well-grown Teats.

Of whatever Breed the Cows be, let the Bull be of the ſame. And let them generally be of as large a Kind as the Paſtures will ſupport in Health and Strength. But it is better to have a Cow of a ſmaller Kind well fed; than one of the beſt Breed in the World ſtarv'd.

It is a general Obſervation among the Farmers, that the red Cow gives the beſt Milk, and the black Cow is beſt for her Calf, which is uſually fairer and healthier than that of the red. But this is not founded on Fact, it is rather Fancy. The red Cows Milk has been long famous; and a Calf of a black Cow is accounted good to a Proverb; but the Breed is the Thing of Conſequence, not the Colour.

The Cow that gives Milk longeſt is the moſt profitable to the Huſbandman; and from what I have obſerved, this is moſt the Caſe with thoſe which are neither very young, nor advanced into Years.

The beſt Time for them to calve is in the Beginning of APRIL, this is moſt favourable both for the Calf and for the Dairy.

The Husbandman should take Care to know rightly the Time of his Cows being to calve; and three Weeks before that, he is to feed her better than usual. She should be put into a rich Pasture, if the Season be so advanced that there is a good Growth of Grass any where: if not she must be well fed with good Hay. And this will be returned many-fold in the Profits of her Milk, which will rise in proportion to the Care that is taken to feed her well just at this Time.

When she has calv'd let her be kept that Day and Night in the House, and let the Water be a little warm'd that she drinks. She is to be turn'd out the next Day, in the Heat of the Sun if well; but she should be taken in at Nights for two or three Days following, and some Water a little warm'd should be given her before she is turn'd out in the Morning.

In hard Weather in the Winter, Cows that give a good deal of Milk, should be fed in proportion; and that should be fine Hay every Morning and Evening, when the Ground is cover'd with Snow; and at other Times once a Day, as there may be found Occasion.

When a Cow does not yield Milk enough at these Seasons, to pay the Price of a good feeding with Hay, let the Fodder be Hay and Straw mix'd; or if still worse, let it be Straw alone. But then it must be Oat Straw, for Barley Straw has a particular Effect in drying up a Cow's Milk; and if given to her in this Condition, because the Quantity she yielded would not pay for better Fodder, the Consequence would be that she would yield none after a very few Days feeding.

When the Farmer has a Scarcity of Hay, or the Price is very high, let him give the Cows which he desires to keep in Milk, Malt Dust, scalded with boiling Water. The Malt Dust swells up vastly with the Water; and when it has stood to be almost cold, it is to be given the Cow in the Manner of a Mash.

If the Cow have this at Times, she may be fed with any Kind of Straw; for this breeds Milk so well, that the other Food will not be able to dry it up while the Creature has the Advantage of its Assistance at the same Time.

About London they feed their Cows very much with Grains. This is a Diet that causes them to yield a vast deal of Milk; but it gives it an ill Taste; and is unhealthful for the Cow, subjecting her to many Disorders. The Malt Dust is as cheap, and answers the same Purpose in a much smaller Quantity, and without the Danger of Illness, or hurting the Milk. It may be bought at Three-pence a Bushel, and it swells so much in the wetting, that this Quantity will very well last a Cow a Week.

In February, when the Pasturage is eaten bare, the Cows are to be taken up into the Cow-house, and fed with dry Meat, according to their Quantity of Milk; those which yield the most being the best fed to keep them to it; and the others in proportion.

Milch Cows should not be blooded unless there be pressing Occasions, and in that Case the Quantity should be moderate, never more than about sixteen Ounces.

The Difference there is between one Cow and another, in the Quantity of their Milk, is so great, that there can no exact Rule be laid down for their Management in Times when feeding comes dear; the best that can be said is, that in proportion to the Profit the Creature brings, should be allowed an Expence in feeding: for a Cow may be kept alive, in Health, nay and in tolerable Flesh, for much less than she can be fed for the continuing to yield her Quantity of Milk.

The Demand there is for the Milk and the Cow, and the Profit that may be at any time made by selling both, is to be consider'd; for the same Thing is worth much more in one Place, and at one Time, than another, in proportion to these Accidents.

In the Neighbourhood of London there is so constant and certain a Demand for every thing, that the Cow Keeper, partly with his early and late rank Grass, partly with Hay, and partly with Turneps and Grains, feeds his Cows in such a Manner, that they are at the same Time in their highest Perfection for Milk, and at any Time fit for the Butcher. But this is not to be done else-where.

The Difference between the Milk of these Cows however, and those fed in the Country, is very great, and all the Advantage is on the Country fed Cows Side. The Grains make the Milk poor, though they yield a large Quantity.

The Price of grazing Ground about London is very great indeed, but this is very well answer'd in the present Article, by the Price at which the Milk is sold. This poor Milk being sold at Three-half-pence the Quart, very bad Measure, while in the Country, but half a Day's Journey from London, 'tis a Penny the Winchester Quart; and in some Places the Milk Quart is full three Wine Pints, while the London Quart of Milk is much less than a Wine Quart.

A Cow in a good farming Country, where Provisions are at a middling Price, is suppos'd, while in Milk, to be worth five Pounds a Year. This is reckoning her to yield about four hundred Gallons in that Time, which, with proper Management is a very decent Computation.

If the whole Quantity of Milk yielded by a middling Cow, be made into Butter, the Quantity will be about two hundred Weight a Year; and there will be a Value beside in the skim'd Milk Cheese, and in the Whey, which last serves for the feeding of Hogs. From this, which is counting at a moderate Rate, we may see the Importance of this Creature to the Farmer, especially if he take Care to keep her in tolerable Flesh all the Time, so that upon a short Notice for fattening, she may be ready for the Butcher.

There is another Use to which the Milch Cow is put in some Places, and which should be here brought to Account, that is, the suckling of Calves. A good Cow will suckle four Calves besides her own, and Grains will then be a considerable Article in her Food, for a great Part of the Year. In this Way of feeding, though the Milk be poor, there is always a great deal of it; and then, though bad for the Uses of the Dairy, it is very fit for the breeding up of Calves.

In Ireland they compute a Cow yields for

the first ninety Days three Gallons of Milk a Day; then for ninety Days more that she yields one Gallon a Day; for ninety more about a Quart a Day, after which she is to be allow'd about ninety Days more dry.

This is the Account of a poorer Kind of Cow than ours, and in generally poorer Pasture, and at more indifferent Feeding: but then the Price is less originally, and the Rent of Land less: so that all Things consider'd together, the Profit may be about equal.

This may be set down as the poorest Account, for no Husbandman ever needs compute lower than this, and the LONDON Account as the highest; and considering all Things, the Difference does not amount to so much, nearly as would appear at first Sight. The Husbandman in general may reckon at a Medium between them.

But there are yet some other Articles which demand the Farmer's Consideration. We have hitherto consider'd the Cow as feeding only upon natural Grasses in our Pastures; but the Custom is become very general of raising artificial Grasses, and is very beneficial: and among other Uses of these, Cows must sometimes be fed upon them.

Now it must be allowed that these artificial Grasses, as they are called, although they feed the Beast very finely, and occasion a great deal of Milk, yet give it an ill Flavour, which runs through all the Things that can be made of it, and consequently reduces their Price at Market.

For this Reason it is not adviseable to feed the milch Cow upon these artificial Grasses, when there is other Food ready for her. The Husbandman should never do this upon Choice; but he may often be led to do it by Necessity, and by the Circumstances and Situation of his Farm. Now in this Case let him use his Cows not for the immediate Sale of Milk, or for the Dairy; but for the suckling of Calves. Upon a very moderate Computation a Cow that suckles four Calves, beside her own, in one Year, will be worth five Pound to the Farmer; which is much the same with her common Produce, any other Way; and if she should be able to suckle five, the Gain would be advanced five and twenty per Cent. She is much more likely to suckle five upon this Feed of artificial Grass, than any other Way; for it keeps her in Heart, as well as causing Abundance of Milk: and in this Case the ill Taste the Milk gets is no Disadvantage: for the Calves shew no Aversion to it; nor is it at all tasted in the Veal.

For the same Reason that suckling is the best Use for Cows under this Circumstance of feeding on artificial Grass, it is also adviseable to prefer it to all others, when the Farmer's Pastures where his Cows feed, happen to abound in such natural Grass as gives a Rankness to the Milk. This is often the Case, where the Grass is large and rushy, or of that jointed Sort common in marshy Places. This Kind of Food yields a great deal of Milk, but with an ill Flavour, but the Calves have no Dislike to it, nor does it do any Harm to their Flesh, either in Taste or Colour.

I have said little of Cheese in the Consideration of the Uses of the Milch Cow; because there are some Grounds where it cannot be made to any great Account, of which more in its Place. In general, in those Counties where good Cheese is not to be made, it should be entirely let alone: in others the Profits, upon a fair Account, considering every Article, seem to be about equal to those resulting from Butter.

The Dairy requires the nicest as well as the richest Milk; and therefore, where the Circumstances will not allow of the Cow's yielding this, her Milk should be always put to other Uses. The fine Milk is the Produce of sweet Grass and good Water. Where the Food is rank, or the Water bad, the Milk will always have a Taste from it; and for that Reason, if the Pasture be ever so good, and the Water bad, it is best for that only Reason to set aside all other Thoughts, and use the Cows for suckling of Calves, if the Circumstances and Situation render that a practicable Matter.

About LONDON, where the Cow is kept in Flesh all the Time of her Milk, so that she is any Day of ready Sale to the Butcher; the Way is as soon as she begins to fail in Milk to sell her, and purchase a lean Cow in the proper milch Condition in her Place.

In the Country something like this is to be done also, tho' more Care and Time is requir'd for it.

One of the greatest Inconveniencies of sucking these Calves is, that they keep the Cow down by the Quantity of Milk they draw, so that she is not ready to go to the Bull again at a proper Season, but misses her Time. When this happens, the Farmer's Business is to fatten her up for the Butcher.

About the Beginning of MAY, or in the Middle of AUGUST, such Cows are to be turn'd into a proper Pasture for fattening, and manag'd accordingly. This will take up four or five Months, and at the End of that Time they will be of ready Sale; and if these Seasons are observ'd for turning them in to fatten, they will be fit for Slaughter at a Time when they bear a Price; for those which are turn'd in at the first named Season, are fit to kill in Harvest Time; and the others a little after CHRISTMAS.

Both these are Seasons when Beef bears a Price; and the Price for which such a fatted Cow is sold, will be enough to purchase a milch Cow with a Calf by her Side; and pay for the Time of her fattening into the Bargain. Thus the Husbandman must contrive and compute, for all Things must be taken into his Consideration, if he would make the most of his Profession. It is easy to get something by it; but he who sets to work upon it with Knowledge, will double his Advantage.

CHAP. XIV.

Of the Calf.

WE have already given the Husbandman proper Directions for the Choice of his Bull, and his Cow, therefore he is so far instructed toward the breeding of the Calf. But a great deal remains to be said respecting its Management,

nagement, for it may, in many Caſes, be made doubly valuable by proper Care. In different Counties various Methods are uſed in raiſing of Calves, according to the Nature of the Demand for them; many Means being employ'd to ſuit their Fleſh to the Taſte and Eye in the Markets, of which we ſhall treat hereafter. There are two Ways of breeding thoſe which the Huſbandman intends to rear. The one is to let them run with the Dam all the Year; and the other is, that of taking them from the Cow when they have ſucked a Fortnight.

In the cheap breeding Counties, the firſt Way is the moſt uſual; and it is commonly allow'd that it produces the faireſt, ſtouteſt and beſt Cattle. It is done alſo with leaſt Trouble to the Owner. Theſe are Inducements of ſome Conſequence, but there are in many Inſtances others on the oppoſite Side that out-weigh them.

When the Calf is taken from its Dam at a Fortnight old, a great deal of Care is requir'd in raiſing it: but in thoſe Places where it is the common Method, all this becomes familiar and eaſy by Uſe. They firſt of all warm a Quantity of flet Milk, and teach them with a great deal of Pains to drink it. There is a great Caution to be uſed in the Degree of Heat they give this. It is moſt natural when it is of the ſame Heat with the Milk juſt drawn from the Cow; and if it be much warmer, or much cooler than this, it is ſure to do the Calf Harm, and often is its Deſtruction.

The Calf, if rightly manag'd, in a little Time gets ſome Strength and Hardyneſs, but when juſt weaned, and at this tender Age, it is very weak and tender.

When thus wean'd, it is to have Milk given to it for a Quarter of a Year; and at the End of that Time, in order to break it from that, ſome Water is to be put to the Milk, and by Degrees more and more till it be only Water, and ſerve for Drink, not for the ſole Nouriſhment.

Before it is brought to this, the Calf muſt be taught to eat dry Food, which is to be done by putting ſome fine Hay in a cleft Stick, and leaving it in his Reach. This ſhould be firſt put in his Way when he is about five Weeks old; and he will ſoon take to it; ſo that by the Time it is proper to wean him from Milk, he will naturally feed on Hay.

When the Calves have got ſome Strength and Hardyneſs, the Huſbandman is to take his Opportunity in fair Weather, in the Middle of the Day, to turn them out to Graſs; they are to be taken in at Night for about a Week, and ſome Milk and Water given them warm; and it is a good Cuſtom to ſet a little to them ſometimes in a Pail in the Field: this may be done occaſionally, till they are able to feed and take Care of themſelves.

Great Caution is to be uſed in the firſt turning Calves out to Graſs, not only that it be a favourable Seaſon, but a proper Kind of Paſture. It ſhould have a ſhort ſweet Graſs, with a good Body, but no Rankneſs.

The beſt Way is to wean the Calves at Graſs, for when they are wean'd in the Houſe by means of Hay and Water, they generally become ſubject to Diſorders. The other is the moſt natural Method, and every Way the beſt.

At about three Years old, ſuch of the Male Calves as are intended for Oxen, ſhould be gelt. This is the Time at which they ſuffer leaſt from it.

In Places where there is a quick Demand, the beſt Method is to fat all the Calves for the Butcher, except ſuch as ſhall be neceſſary to keep up the Stock. This Demand is commonly largeſt near great Towns, where the Price of the Calf is high, and where the Grounds are not profitable to breed upon, ſo that it is a particular Circumſtance: cheaper Countries being fitter for breeding.

As the Price of the Calf in theſe Places depends upon the Fatneſs and the Colour of the Fleſh, the great Care of the Owner is to be turn'd to theſe two Articles: in the which if he ſucceed perfectly, his Calf will fetch as large a Price as a good Heifer. In order to make the Calf fatten, and have a white Fleſh, the common Method is this. They keep them extreamly clean, giving them freſh Litter every Day, ſpreading the new upon the old; and always keeping a Couple of large Lumps of Chalk hung up in Corners of the Coop, in their Reach; and where they cannot foul it by treading upon it, or by their Dung or Urine.

The Calf will be continually licking theſe Chalk Stones, and their Whiteneſs communicates itſelf to the Fleſh throughout his whole Body.

Another Care is, the proper building of the Coops in which Calves are to be fatten'd: the two great Conſiderations in theſe are, the keeping them cool and dry. For the firſt Purpoſe they build them in Places where there is little Sun; and for the other, they raiſe them three Foot from the Ground, ſo that the Urine and all other Moiſture naturally runs out.

When the Calf is in this keeping, well fed, and carefully look'd after in every Reſpect, it is twice at leaſt blooded: once of theſe Times is at about five Weeks old, and the other Time a little before it is killed.

When a Calf purges, the Cuſtom is not to let it ſuck altogether, for the Milk of the Dam often throws it into this Diſorder, which certainly waſtes its Fleſh. In this Caſe they give it Milk with Chalk ſcraped into it, which has a double Effect; ſtopping the purging, and throwing more of the whitening Matter into the Fleſh. They ſcrape the Chalk very fine for this Purpoſe, and after mixing it well with the Milk, they pour it down the Calf's Throat with a Horn.

Often it happens that this will not remedy the Diſorder, and the Calf is like to be ſpoiled. In this Caſe they uſe the Cold Bath for it; and give it ſome Bole Armenick, and Chalk mix'd up with Milk into Balls.

If this does not anſwer, they know not what to do farther. But I have found that in the worſt Purgings to which theſe young Creatures are ſubject, a ſmall Doſe of Diaſcordium made without Honey, mix'd with Port Wine and Water made warm, and given with a Horn, will do more good than all their Remedies.

The

The Calf muſt not have any Milk for three Quarters of an Hour before, nor an Hour after this Drench, but it may lick as much Chalk as it pleaſes. If this does not anſwer in the firſt Doſe, another may be given twelve Hours afterwards, and this rarely fails. The Quantity to be given each Time is a Dram. This never hurts the Colour or Taſte of the Fleſh.

This Purging is the moſt common Diſorder the Calf falls into, but it may be diſordered in the other Extream, and that is full as bad. If it be coſtive, the Fleſh of it will never be delicate. When any Tendency to this is obſerved, the proper Method is to give a little Manna; and the beſt Way of giving it is this: buy about an Ounce of ordinary Manna, which they ſell at a ſmall Price at every Druggiſts; diſſolve it in a quarter of a Pint of Water, and add a Spoonfull of Brandy. Thicken up this Liquor with fine Wheat Flower, and make it into Crams, give the Calf three or four of theſe every Morning after he has been ſucking, and dip them in Milk to make them go down. Repeat this till the Calf is right in this great Reſpect; and then leave it off.

Theſe, as they are properly ſpeaking, Medicines for the remedying of Diſorders, might have been reſerved to their Places in this Work, in a ſucceeding Book, but as they immediately concern the Management of the Calf for Slaughter, I have ſet them down in this Place, not willing to give the Reader the Trouble of a needleſs Reference to another Part.

The Manner of bleeding Calves is this. The firſt Time it ſhould be done in the Neck, and Care muſt be taken not to draw too much. The ſecond Time it is beſt done by cutting off a Piece of the Tail, and if this do not bleed ſo much as might be expected, it may be repeated at two or three Day's Diſtance, by cutting off another Piece, which will bleed juſt as the former.

One very uſeful Effect the Chalk given to Calves has, beſide the whitening, which is, preſerving the Fleſh, for it keeps it dryer than it would otherwiſe be, and the Wetneſs is what makes it ſo ſoon taint.

The Cow is ſubject to great Irregularity in breeding of her young. Very frequently there are Parts of a ſecond Calf growing out of the firſt; and theſe monſtrous Productions are ſhewn about for their Curioſity.

Nature often is ſo abundant in this Species, that the Young come by Twins: and we have Inſtances of Cows that have, for ſeveral Years together, always brought forth two Calves at a Time, as if it were the natural Condition of the Animal. Dr. PLOT, in his natural Hiſtory of STAFFORDSHIRE, tells us of a Cow at DUNSTALL, in that County; that for three ſucceſſive Times brought forth two Calves each Time, and a third Time three. Thus having no leſs than nine Calves in three Years Time.

The Bull was doubtleſs the ſame to this Cow, and to many others, which we do not find recorded upon this Account, as having brought forth their Young in any particular Manner; whence we may naturally infer, that in the Caſe of Twins in our own Species, as well as other Animals, the Cauſe of them is in the Female more than the Male.

One would not build ſuch a Suppoſition upon a ſingle Inſtance, but the ſame Author tells us of another Cow that had ſucceſſively three, two, two, and then three again, ſo bringing ten Calves in the ſame Space of Time as the other nine: and it appears from Obſervation, in almoſt all theſe Inſtances, that the Creature who thus brings an abundant Number of young at any one Time, continues to do it.

MORETON, who in his Hiſtory of NORTHAMPTONSHIRE, mentions Inſtances of a like Kind, adds, that when the Twins are one Male, and the other Female, the Cow Calf, if it be brought up, is always barren. In that, and in ſome of the adjoining Counties, they ſhew a Kind of Cows which they call Free Martins, they have large Horns like an Ox; and they ſay they partake of both Sexes. Theſe are ſaid to be the Cow Calves where there have been Twins. And they add, that when the Twins are both Female, they are prolifick like other Creatures of the ſame Species.

I have ſet down theſe Articles which are Matters of Curioſity, merely for the ſake of farther Enquiry. Theſe Writers are too apt to take Things upon Report, and we know how idle many of the Stories are, which are confidently and univerſally propagated among the Farmers in moſt Countries; and believ'd by the Vulgar, becauſe they often hear them.

CHAP. XV.

Of Sheep, and the ſeveral Breeds in this Country.

NEXT in Value and Conſideration to the larger of the Horned Cattle comes the Sheep; an Article of vaſt Concernment to the Farmer: cheap in the Purchaſe; eaſily fed; and returning a great Profit by many ſeveral Ways: even its Dung upon the Land often paying for all it eats while fed upon it.

We have already adviſed the Farmer in the Choice of his larger Cattle, to proportion their Kind to the Degree of Richneſs in his Land: it is not the Fortune of every Huſbandman to labour upon a fruitful Soil: but the worſt is not without its Uſes; and Sheep are a Stock for ſuch as will not ſupport the larger Kinds. We ſee them thrive upon the moſt barren Downs; and the Farmer will always find them ready to fatten upon ſuch Grounds as will not keep the other Kinds alive.

As the Oxen of ENGLAND are of very different Breeds, though all the ſame in Kind, ſo it is with the Sheep, which differ extreamly according to the ſeveral Breeds in different Places; and are therefore ſuited one to one Kind of Land, and another to another.

We ſhall adviſe the Huſbandman to great Caution, in the ſtocking his Farm with Sheep: and this under two Heads, firſt, with Reſpect to the Breed, and ſecondly, for his Choice of the Creatures themſelves; for there are, in every Breed, many that are much finer than others,

and theſe he ſhould chuſe. Half the Profit that might be made by this Part of the Huſbandman's Stock, is loſt by Careleſſneſs in the firſt Choice, and in the following Management: but an Error in the firſt Choice is the moſt fatal, becauſe it is irrecoverable, except by beginning over again. We ſhall therefore firſt conſider that, and laying before the practical Huſbandman the Properties and particular Uſes of the ſeveral different Breed of Sheep that we have in England, ſhall adviſe him in his Choice according to his main Deſign, his beſt Advantage, and the Nature of the Land he has to ſtock with them.

With reſpect to the Fineneſs of the Wool, there is a ſmall Breed, diſtinguiſhed by their black Face and thin Coat, that exceed all others. They bear but a ſmall Quantity in Compariſon of many, but the Quality of it makes Amends. Theſe are eaſily known by Sight. They were firſt rais'd in Herefordshire and Worcestershire. And for that Reaſon are known in many Places by the Name of the Herefordshire or the Worcestershire Breed. A dry, barren, and expoſed Paſturage will very well feed this Kind, for they are hardy; and the ſhorter the Graſs on which they feed, it is obſerv'd the finer the Wool. They are alſo excellent for the Table, the Joints being ſmall and full of a fine Gravy. We ſee this Kind kept in many Parts of England, in Gentlemen's Parks and Lawns, and they every where make a pretty Appearance.

The Kind moſt oppoſite to theſe are a large, tall, and heavy-loaded Sheep: theſe have ſtrong Limbs, and a ſtout Gait in walking: they carry a great deal of Wool, but it is coarſe. Theſe were firſt bred in Lincolnshire, and in ſome of the adjoining Counties; and are fond of living in Salt Marſhes. They have been taken into many Parts of the Kingdom, to other Ground, where they do not keep entirely to their own Nature: and yet are called from the Place whence they were brought, the Lincolnshire Breed.

The Fleſh of theſe is large grain'd, but moderately taſted, and no where very much eſteem'd. However, as they are obſerved to ſucceed better than the other Breeds, in Places toward the Sea, it may be proper for the Huſbandman who has Land in ſuch a Situation, to take ſome of them: though not for his whole Stock in this Kind.

Thirdly, there is a Breed between theſe two Kinds, which in general ſhould be prefer'd to either. This is a large, tall, and ſtrong Sheep, of the beſt Shape of any, and having the deepeſt Coat of Wool. This was originally fed in ſeveral of our midland Counties, and has thence been called by ſome the Midland Breed; and by others, from ſome particular Counties famous for them, the Leicestershire or Northamptonshire Breed. The Wool of this Kind, though not altogether ſo good as that of the ſmall black faced Sheep, is greatly preferable to that of the Lincolnshire Breed; and the Quantity is ſo much greater than that of the ſmaller Kind, that it very well makes amends for its inferior Quality.

The Fleſh of this Sheep is the common Mutton, not in any thing particular for Goodneſs or Badneſs: and it will do very well upon the common Paſture Grounds, and thrive upon every common Kind of Food. For theſe Reaſons it is fit that theſe Sheep ſhould be moſt generally bred.

When the Huſbandman has very poor Paſture Grounds, let him take the Herefordshire Breed; and when he borders upon the Sea-Coaſt, or upon the Shores of large Salt Water Rivers, let him prefer, in Part at leaſt, the Lincolnshire Kind: but when he has none of theſe particular Reaſons to byaſs him, let him prefer this midland Breed to any other.

To theſe three, which may be call'd the general Breeds of Sheep, I ſhall add a few Words on two other Kinds.

The Sheep bred in the Northern Parts of this Kingdom, are a large and big bon'd Sort; they approach to the Lincolnshire Kind in Shape; but their Wool is harſh, rough, and hairy, theſe are called by ſome the Yorkshire Breed.

Their Fleſh is inferior to that of ſeveral other Kinds, as well as their Wool; but they have an Advantage over the others, in that they will ſtand the coldeſt Weather, and take Care of themſelves where ſome of the tenderer Breeds would be loſt. This may recommend them to the Huſbandman whoſe Lot has thrown him far North, where the other Kinds will not thrive; but he ſhould not introduce them into his Farm in any other Situation, for they are leſs profitable than any others.

The laſt Kind, or Breed, to be mentioned, is in a Manner peculiar to mountainous Countries; and is moſt frequent in Wales. It may therefore be called the Welch Breed. This is a ſmall, but well-ſhaped Sheep; and ſo hardy that it will live any where. The Fleſh is excellent for the Table. But the Wool is not only ſmall in Quantity, but is the worſt produced by any Breed of Sheep in this Country.

The Huſbandman will ſee by this Account, that it never can be his Intereſt to admit this Breed among his Stock, unleſs compelled to it by the Particularity of his Situation. The little black fac'd Sheep of Herefordshire has the ſame Advantage in the Excellence of its Fleſh; and it has, into the Bargain, the fineſt Wool in the World. Therefore it is highly to be prefer'd, where it will thrive; and it will do on very poor and very expoſed Ground. However, if at any time the Farmer finds his Paſtures ſo poor, ſo expoſed, and miſerable, that they will not ſupport this Kind, all he has to do is to call in the other, or Welch Breed, which will live any where.

CHAP. XVI.

Of the Choice of Sheep.

HAVING laid before the Huſbandman this Account of the three principal different Breeds of Sheep in England, and the two other Kinds that are, in a Manner, particular to certain Places, the next Part of our Care muſt be, the inſtructing him in his Choice, not only of the Breed he ſhall fix upon, for the Grounds of that Choice have been laid down already, in their ſeveral Characters; but of the particular Creatures he

he ſhall fix upon in the Breed that is moſt ſuited to his Purpoſe.

But to this Particular let us premiſe a few Words upon his general Choice, that is, as to the Breed. He ſees here five ſeveral Kinds of Sheep, ſome large, others ſmaller; and ſome yielding a greater, ſome a ſmaller Quantity of Wool, which is alſo on one Breed fine, and on another coarſer. He has his Choice given him among all theſe, for we ſuppoſe him not yet to have begun ſtocking his Farm with this Article: it would be natural for him to prefer at once the fineſt Kind as moſt profitable; but let him not only remember, but ſtrictly obſerve what we have juſt laid down, that every Breed will not ſuit every Paſture.

He has now ſeen what are the Kinds of Sheep: let him examine what is the Nature of his Land; and when he has impartially conſider'd this, let him fix upon that Breed which will thrive beſt on that Kind of Paſturage he has at his Command, for this we have expreſly told him with reſpect to each; and let him then purchaſe for his Farm that Breed which he ſees will be moſt ſuited to thrive on it.

This he may be aſſur'd of, and he may extend the Rule farther than barely to his Sheep, that he will have more Profit from the very worſt Kind that ſhall thrive upon his Land, than he poſſibly can from the very beſt that ſhall ſtarve upon it.

One Thing farther is to be noted before we come to the particular Choice, that is, the Difference of the Land which he is to bring them to from that whence he purchaſed them: this muſt be in this Reſpect, as has already been caution'd upon other Articles, always in Favour of the Land to which they are brought; for any Breed whatever will decline upon being brought from a richer Paſturage to a poor one.

Let the Farmer therefore ſee that he buy not only a kind ſuited to his Grounds; but that he buy them from a worſe Land than his own, becauſe upon that will depend their immediate thriving.

Having thus ſettled the general Points, let him proceed to the Care he is to uſe in the Choice of each particular Sheep.

Whatever Breed they are of, let him obſerve that what he purchaſes are ſtout, hearty, well made, and big boned: let him ſee that the Wool of whatever Kind or Depth, be ſoft to the Touch, and ſeem fatty in the handling; and that it be clean and well curled.

Sheep of this Condition, whatever Breed they belong to, always bear the largeſt Quantity of Wool according to their Kind: and theſe are Marks alſo that make them bring a Price at Market. The Butcher has his Rules for judging as regular as the beſt Farmer, and theſe are the Things after which he principally enquires to ſettle the Creatures Value.

In the laſt Place, we are to give Directions for the Choice of Sheep to breed. This is a very material Article, and muſt be well regarded. Let the Farmer chuſe his Ram by theſe Marks; let him be young, handſome, and well ſhap'd, of whatever Breed, ſee that his Wool be clean and grow well; and let the Skin underneath be of the ſame Colour. Let his Body be large and long; his Forehead broad, round and riſing. Let his Eyes be large and of a cheerful Aſpect, and his Noſtrils ſtrait and ſhort.

The Sheep without Horns, which are called the polled Breed, are accounted the beſt Breeders; this is eſtabliſh'd upon ſo long and repeated an Experience, that the Farmer needs not doubt it.

In the Choice of the Ewe for breed, let her Neck be large and upright, naturally bending like the Neck of a Horſe. Her Back ſhould be broad, and her Buttocks round: her Tail ſhould be thick, her Legs ſmall and ſhort; and her Wool ſhould be thick and deep, and ſhould cover her every where.

Of all Things let the Purchaſer take Care that they be ſound, and, to know that, let him examine whether any of the Wool be wanting: let him ſee that the Gums be red, and the Teeth white, the Felt looſe, but the Wool firm, the Breath ſweet, and the Feet not hot.

With reſpect to the Age, two Years old is the beſt Time to have them at. They will bear good Lambs till they are ſeven Years old: and their Age is to be known by their Mouth. When they are one ſhear they have two broad Teeth before; when two ſhear, they have four; when three ſhear, they have ſix; and when four, they have eight: after this their Mouth generally begins to break.

By this the Purchaſer will be able to gueſs at the Age of his Sheep; and, as to their Condition, nothing ſhews it more than the Dullneſs of their Eyes, and the Looſeneſs of their Wool. If theſe Marks be upon them, let not the Farmer purchaſe them by any Means, for they will never ſtand.

CHAP. XVII.

Of the breeding of Sheep.

THE Rams and the Ewes being choſen for breeding according to the foregoing Directions, the Huſbandman is next to conſider what will be the beſt Time for putting them together. In this, as in other Reſpects, let it not appear that I lay more upon his Mind than I need. It is true that a great deal more Care is here recommended, than uſually is taken by Country People on moſt Occaſions; but not more than is proper or requiſite. The Principle on which I have ſet out in this Treatiſe is, that the Huſbandman by Induſtry and Knowledge of his Buſineſs, may obtain much larger Profits than the common Run of Perſons in this Buſineſs are content with; therefore although leſs Care and leſs Foreſight than is here recommended may do; yet he who uſes the moſt will have the largeſt Gains. I expect my Farmer in every Article of his Buſineſs, to conſider the Event before he fixes upon the Means; and always to have the End in his Eyes when he is about to make a Beginning.

Thus in the preſent Inſtance, before he puts his Rams and his Ewes together for breeding, I adviſe him to compute the Time of their go-

ing with young, and ſo to know when his Lambs will be brought forth. When he has computed this, let him ſee whether it will be a convenient Seaſon for him; and which will be beſt. Let him conſider at what Time of the Spring his Graſs will be fit to maintain the Ewes and their Lambs, and then put the Rams and their Females together ſo long before, that will bring the young out at a proper Time.

Let him conſider whether if they fall early he ſhall have Turneps to ſupport them till the Graſs comes: for I have often ſeen very great Miſtakes in this Reckoning: and many a Time the Huſbandman, for want of due Care in this Reſpect, has loſt both his Ewes and his Lambs for want of due Food.

The prudent and conſiderate Farmer is to take Care before he puts his Sheep for breeding, he is ſure not only of a Support for the young and their Dams when requir'd; but that it be a ſufficient and good Food for them. That which will keep them alive oftentimes, will not be ſufficient for their thriving. There muſt be Plenty of what is good in its Kind, for if there be a Defect in either Quantity or Quality, the Lambs will be ſtunted at firſt, and this is an Accident they very difficultly recover afterwards.

The Time of the Ewes going with Lamb is twenty Weeks, and the beſt Seaſon of the Year for them to yean is, toward the Middle of April; except where there is very forward Graſs or Turneps. But if on any Occaſion from the Circumſtances of the Farm, or any particular Conſideration, it is neceſſary to have them yean much earlier, they may be put together ſo as to come in January or February.

In this Caſe there will require a great deal of Care to be taken of the Lambs for ſome Time. All Lambs are very tender when firſt brought forth, and if they are not tended, the Magpyes, and other Birds will peck their Eyes out: but the Coldneſs of the Seaſon keeps ſuch as fall in January or February tender and weak much longer than thoſe which are brought forth at a more advanced Time in the Spring; and therefore a nicer Care is requir'd to breed them up; and it muſt be continued a longer Time than on the other Occaſion.

As to the Land to breed Sheep upon, when the Farmer has Variety, and can take his Choice, let him obſerve theſe ſeveral Qualities in the different Kinds, and conduct himſelf accordingly. A rich Paſture breeds well ſhap'd and tall Sheep, according to their Kinds; and ſuch as have a ſhort Graſs breed a lower but well ſet Sheep. Thoſe which are bred in mountainous or woody Places, are commonly ſmall limb'd and low.

In general, dry Paſtures are the fitteſt for this Purpoſe: all wet Grounds, and ſuch as are liable to be overflow'd, being hurtful; excepting only the Salt Marſhes, which, for the proper Kinds, ſucceed very well.

The Farmer ſhould keep all this in Mind, but at the ſame Time remember, that theſe Rules are ſubordinate to thoſe more general ones, which have been deliver'd already. The Breed of his Sheep is the great Article of Conſideration in reſpect of their Size, and he has already been inform'd what Breeds ſuit what Lands: thoſe more eſſential Conſiderations being kept in Mind, theſe leſſer ones are of great Uſe.

Let the Farmer who is about breeding of Lambs, ſave the Graſs and Weeds that grow in the Lands he deſigns to fallow in Winter, that is, from Christmas; and let him turn his Ewes and Lambs into them in March. If there be a mild Winter, this will be a great Help to them.

When Sheep are to be turn'd into Wheat or Rye to feed, the Farmer muſt take Care it be not too rank before they are put into it, for in that Caſe it gives them Purgings, and other Complaints.

No Cattle whatſoever ſhould be fatted while they are going with young, for nothing is more dangerous to them: they ſhould therefore be kept upon a moderate, or rather poor Paſture all the Time they run breeding, except the three laſt Weeks. This is a Rule to be more carefully obſerv'd with Sheep than any other. If they be fed too high the whole Time, it will go hard with them in yeaning; but if they are not put a little into Heart before they come to it, they will want Strength; and they will alſo want Milk for the Support of the Lamb.

The proper Time of weaning a Lamb is at four Months old: but in general there need no Care or Caution to be uſed at all. In moſt Places where Things are properly manag'd, Nature does this, and the Owner knows nothing of it: in ſome Paſtures it is alſo the Preſervation of the Lamb to keep ſucking.

When the Farmer has Plenty of good Graſs, and his Rams always run with the Ewes, he need not give himſelf any Trouble about the weaning of the Lambs. The Ewe will in this Caſe go to Ram at a proper Time of her own Accord; and ſhe will then become dry, and the Lamb will be wean'd naturally.

In ſuch Paſtures as are ſubject to give Sheep the Rot at certain Times, it is always beſt to let the Lambs run by the Ewe; the longer the better. Theſe tender Creatures are more ready to come to harm than the full-grown ones in thoſe unſound Places: and ſucking is the beſt Preſervative againſt it: for they are ſeldom found to fall into that Misfortune while they have Milk.

If the Farmer have ſuſpicious Paſtures, and finds that his Lambs want Milk, it is beſt to ſell them at once to the Butcher: for it is not the running by the Ewe that will preſerve them, ſhe can be of no Service againſt ſuch an Accident, if ſhe wants Milk for their full Support.

Thoſe he Lambs that are intended to be bred as Rams, ſhould be ſeparated from the reſt, and the others gelt in Time. The ſooner this is done the better: for every Creature bears this Operation beſt while it is tender, and is with the Dam.

If this Operation have been neglected at a proper Time, it muſt be done toward the End of September, at which Seaſon it is beſt to ſeparate the Breed for this Purpoſe, and ſee it be done perfectly.

CHAP.

CHAP. XVIII.

Of the ſheering of Sheep.

WE come now to a very conſiderable Article in the Value of Sheep, that is the Wool; and this, like every other Part of the Huſbandman's Profits, may be enlarg'd greatly by due Care and Management.

There are two Articles in the Condition of the Wool which enhance its Price. Theſe are Fattyneſs and Cleanneſs. And it is in the Owner's Power to give it theſe in a much greater Degree than they otherwiſe would be, by his Care and Attention. The firſt will be increaſed by the Time of ſhearing the other by Cleanlyneſs.

The Fattyneſs of the Wool will never give it any Value, unleſs it be at the ſame Time clean; and the Cleanneſs will diſcover its Imperfection, inſtead of enhancing the Price, if it be not fatty.

This Fattyneſs of the Wool is owing to the Creatures ſweating, and therefore there muſt be ſome hot Weather paſt before it is ſhear'd, that it may have ſweated well: not once or twice, for that will anſwer no Purpoſe: but ſeveral Times for Days together, that the Moiſture may have lodg'd itſelf about the Wool, and in a Manner oiled it ſo, that the neceſſary waſhing of the Creature for Cleanlyneſs, ſhall not be able to carry it off.

Unleſs the Sheep have ſweated well before the Waſhing, that will do harm equal to its good, for as much as it increaſes the Price by Cleanneſs, it diminiſhes it by taking off the Fatneſs. It is very neceſſary Sheep ſhould be well waſh'd before they are ſheer'd: but the Farmer is to know at the ſame Time, that unleſs they have well ſweat in their Wool firſt, this will hurt it.

Upon this Foundation depends all the Art of Sheep-ſhearing. The beſt Seaſon of the Year for doing it is toward Midſummer. But let the Weather determine, and let not the Farmer be carried away by the Name of any Day, or Month, againſt the Uſe of his Reaſon.

June has been commonly made the Month for Sheep-ſhearing; for this plain Reaſon, that at this Time of the Year there commonly has been ſome hot Weather to ſweat the Sheep; and there follows hot Weather after it. But as this is the Reaſon why June is proper, if any Year the Seaſon prove very cold in the firſt Part of Summer, let him defer it till July; and, on the other hand, if very hot Weather come in early, let him go to ſhearing in the End of May.

In general, if the End of May be hot, he is to begin early in June; and if the hot Weather have not come in till the Beginning or Middle of June, he is not to ſhear his Sheep till the latter End of that Month. And in this Manner let him who would ſucceed well in the Huſbandman's Buſineſs, conduct himſelf in every Article. Let him know the Practice of others according to the common Rules: but let him examine the Reaſon of it in every Article; and while others follow it blindly, let him pay his Submiſſion to it with Diſcretion. I would not have him ſet himſelf up as an Oppoſer of the common Methods, unleſs where they are palpably wrong; but underſtanding their Origin and Foundation, he will often find it convenient to depart a little from them; and will always find the Advantage of that Liberty when it is founded upon Reaſon.

When the Huſbandman has on theſe Principles ſettled the Time of ſheering his Sheep for that Year, whether it be the End of May, the Beginning, Middle, or End of June, or the firſt Week in July: for it ought not to be later than that for many Reaſons; the next Care is to prepare for it by ſettling the Time of waſhing them, and giving them Opportunity to dry themſelves clean.

For this Purpoſe the Place of waſhing is to be fix'd upon, and a Piece of clean and dry Ground in which they are to run till they be dry'd, and where they can't get freſh Dirt. For Convenience Sake this Piece of Ground, and the waſhing Place, ſhould be as near one another as may be. So if the Farmer have his Choice of two or three ſuch Places, let him prefer that which is neareſt the Water; and if he have but one, and have good Convenience of Water, then let him make the waſhing Place in the Spot neareſt of all to this Ground.

Though it is very needful that the Sheep be waſh'd before it be ſhorn; yet it muſt not be ſhorn while it is wet: and if ſuffer'd to run at random afterwards, the waſhing would not be of much Effect.

The whole Matter, which is very plain and eaſy, being thus underſtood, and all Things ready, let the Farmer proceed to the firſt Article, the waſhing of his Sheep. Let him ſee that this be done thoroughly and carefully. There is a way of ſlighting Buſineſs in ſuch a Manner, that it might as well have been let alone; and this is too common in the Article of waſhing of Sheep, which is a Thing very troubleſome to do well; and that eaſily hides Faults, for if the Farmer does not ſee that it be done well while they are about it, he will not be able eaſily to know afterwards, whether it be well done or no.

The Preſence of a Maſter is always uſeful while Servants are employ'd for him; but in no Article more than this, for Cleanlyneſs will add conſiderably to the Price his Wool ſhall fetch.

When every Sheep has been thus carefully, thoroughly, and well waſh'd, let them be all turn'd together into the Piece of Ground deſign'd for their Reception, and there be left to run till they are dry. This, according to the Weather, will take two, three or four Days, rarely more, for the Seaſon is ſeldom very unfavourable at that Seaſon of the Year.

All Things being now ready, let the Shearer get to work, and 'tis worth the Farmer's while to take a great deal of Care to have one who underſtands his Buſineſs: for an ignorant or careleſs Fellow at this Work, may do his Maſter

more Damage in one Day, than a Month's extraordinary Wages.

In this let him over-ſee every thing with his own Eye, as in the waſhing; and if he perceive any Sheep half waſh'd when it comes to the Hands of the Shearer, let him ſend it to be waſh'd over again.

Let the Farmer order his Shearer to be careful not to hurt the Sheep, and let him have his own Eye over him, that he do not cut them, or prick them with the Point of his Shears, for the Flies will immediately take Advantage of theſe Wounds, and torment the poor naked Creatures to Madneſs. Finally, let him ſee the Wool be carefully taken off, and well wound up.

It is a very good Cuſtom that ſome have, of ſhearing their Lambs together with the Sheep: although others very much condemn it. I would have the Farmer never fail to do this; but then he need not be very ſtrict and exact about it all over. The principal Care is to ſhear them well behind.

Before they come to be ſhorn it is very neceſſary to cut away the Wool of their Tails, and juſt behind, that the Dung may not hang on it, which makes the Creature ſore, and brings the Flies in the ſame Manner as a Wound with the Shears. When they come to be ſhorn they ſhould be cut cloſe behind; but very little before.

Sheep do much Damage to their Wool by lying in dirty Places, which they often will do, for they are not naturally a very cleanly Animal, as well as in their running in the Day Time. For this Reaſon the Wool of the ſame Breed of Sheep, is much finer in thoſe Counties where they houſe them in the Night, than in other Places. In Gloucestershire, and ſome of the adjoining Counties, they houſe the Sheep always at Nights, and litter them with clean Straw. The Expence of this is very well paid by their Dung, which, together with their Urine mixing among the Litter, enrich'd alſo by their Sweat, and the Fatneſs of the Wool, makes a very fine, rich, and pretious Manure.

We have treated largely of the Uſe of houſing Sheep, under the Article of their Dung, in its Place. The Method there preſcribed of throwing in ſandy or other Earths, to be enrich'd by the Dung and Urine of the Animal, is better than this of Straw, when the Article of Manure only is conſidered; but taking the Wool alſo into Conſideration, this by Straw is greatly preferable.

'Tis from the Conſideration of theſe ſeveral Methods, practiſed in different Places, and weighing the Advantages of each, that the judicious Huſbandman encreaſes his Knowledge; and his Profits will always be enlarged in proportion.

From what has been ſaid on theſe Heads ſeparately, and in their proper Places, he will now, ſumming up the whole together, be able to determine upon a Conduct in the Management of his Sheep, which although built upon the Practice of different Counties, in ſeparate Articles, is preferable, upon the whole, to any one of their Methods ſingly.

Thus if he uſe the cover'd Fold, for the Sake of raiſing a Quantity of Manure with Sand and other Ingredients, during the reſt of the Year, he will do well to throw in clean Straw, by way of Litter, for the four or five Weeks before their ſheering. This will give him a conſiderable Advantage as Manure, if not equal to what he gets the other Way, and what he loſes in that Reſpect, he will gain with Encreaſe by the Fineneſs of the Wool.

Upon this Principle alſo the Huſbandman may very reaſonably be directed to have a Kind of cover'd Fold, ever ſo ſlight, on the Ground where he turns in the Sheep, between the Time of waſhing and ſheering. Let him ſtrew this with clean Straw, by way of Litter; and ſee the Sheep all driven into it at Night. This they will very readily do, becauſe they will feel cold after their waſhing; and by this Means, lying clean and dry, they will keep the Wool very nice for the ſheering. Nay there is a Cleanlyneſs in the Nature of Straw that will be a great Advantage, for they will rub themſelves upon it to a clean bright Hue in the Wool, which it will not have any other Way.

CHAP. XIX.

Of the breeding up Houſe Lambs.

THE Price of Houſe Lamb, at early Seaſons, is ſo conſiderable, that it may be very well worth while for the Huſbandman who is ſituated near large Towns, or where there is a Demand for it, to raiſe ſome for this Purpoſe.

To this End three Things are principally to be conſidered. Firſt, to have a proper Kind of Sheep; ſecondly, to put the Rams and Ewes together at a right Seaſon, that the Lambs may fall early; and laſtly, to provide proper Pens in an Houſe for the receiving and nurſing up the Young: for their tender Bodies require a great deal of Care at ſuch unnatural and ſevere Seaſons.

There is a Kind of Sheep of the midland Breed, but a little ſmaller than what we commonly underſtand by that Name; otherwiſe very like thoſe of the Leicester and Northamptonshire Kinds; theſe are remarkable for their naturally lambing very early. If left to themſelves they will bring forth about the Middle or latter End of December; and therefore, if properly put together by the Huſbandman, who underſtanding the Benefit of early Lamb, and computing the Time, contrives accordingly, they will come ſomewhat earlier. Theſe Lambs brought forth in the dead of Winter, may be eaſily rear'd at Home, and will bring a Price that will very well anſwer the Trouble.

This particular Kind of Sheep is bred principally in Hampshire and Wiltshire; and is known among the common People by the Name of the Wey-hill Sheep.

The Huſbandman who will proceed upon proper Principles, is always to prepare in Time for every thing. When he finds from his Situation and Circumſtances, that he may have a Demand for Houſe Lamb, at a good Price; and that he has Conveniences for raiſing it, let him take his Opportunity to buy ſome of theſe Wey-hill Sheep at the beſt Market, and be particularly careful that they are, in every Reſpect, ſound and free

from Blemiſh; chuſing them ſeverally, the Rams and Ewes, according to the general Direction laid down here for that Purpoſe, which anſwers for one Kind of Sheep as well as another.

Being provided with a proper Number of theſe Sheep, let him not leave their Time of breeding to Chance, but keeping them ſeparate, till a proper Seaſon, then put them together, that they may copulate in ſuch Time as to bring forth their Lambs at the Seaſon he deſires.

After this no farther Care is neceſſary than that the Ewes are fed in a Paſture not too rich, for the greateſt Part of their Time; but about three Weeks before their lambing, they are to be brought into a richer Feeding; and as the Time of their bringing forth is very exactly known, let there be due Care taken of them, and of the Lambs as they fall, that neither are hurt by the Severity of the Seaſon.

The Sheep being thus carried on to their Time, and the Lambs brought forth, the laſt Care is the bringing them up for the Service of the Table; or, according to the Farmer's Reckoning, for the Purchaſe of the Butcher.

A great many Arts are uſed to this Purpoſe; and a great Number of different Directions have been given about it, by thoſe who have pretended to have great Knowledge; but the whole may be delivered in a few Words, and the Huſbandman who ſhall ſet about this, upon the Principles of good Senſe alone, will find that moſt of thoſe Cautions and curious Directions that have been ſo elaborately delivered, might have been ſpared.

The whole Care conſiſts in two Articles, the keeping the Lambs warm, and the feeding the Sheep in ſuch a Manner, that they may be able to ſupply them with a rich Milk, that will fatten them. There can be no great Difficulty, and certainly no Myſtery in this, ſo that it is idle to pretend to Secrets about it; and more idle in any to deter the Huſbandman from it, under Pretence of his not underſtanding how to do it. Let him ſet about it with theſe Precautions, and look to the Lambs himſelf with due Care, to ſee they are warm and clean; and feeding their Dams as he ought to do, he cannot fail.

The Severity of the Seaſon would deſtroy the Lambs, if they were left to ramble about with the Ewes; and the Scarcity of Food, at this Time of the Year, would make them unable to fatten them by their Milk, if they were not provided accordingly; but good Food will make rich Milk, and a due Portion of Food will yield it in due Quantity. This is all that is needful, and all this may be brought about in this eaſy Manner.

Sometime before the Ewes are expected to bring forth, let proper Pens be built up for them, in an Houſe that is warm, but not ſhut up cloſe, for if they have not Air they will not thrive with any Food.

As ſoon as they are brought forth let them be carefully put into theſe Pens, and from that Time watch'd and tended, that they may be always warm, dry, and clean.

We have already directed that the Ewes, toward the Time of their bringing forth, ſhould be put into a richer Paſture than that they had run in before: this will provide them a Stock of good Milk, and now they have lamb'd, this is to be enlarged and enriched, by giving ſtill better Food.

The beſt Food for this Purpoſe is Turneps; but where they are not in Readineſs, the Ewe, beſide her rich Paſture, muſt have, at Times, Hay, Bran, and Oats given her.

It is fit the Huſbandman ſhould know what to do, in Caſe of a Deficiency of what is proper, but theſe other Supplies do not enrich the Milk in the Manner of Turneps; therefore he who proceeds upon our prudential and careful Principles, muſt not fail to have Turneps for the Occaſion.

The Ewes are to be brought into the Houſe three or four Times every Day, to ſuckle the Lambs; and in this Manner, as thoſe young Creatures are kept very cleanly and comfortably, and feed to their Fill upon rich Milk, and upon nothing elſe; they will fatten quickly, and their Fleſh will naturally be exceedingly white and delicate.

The whole Art of this profitable Part of the Huſbandman's Buſineſs, is compriſed in theſe few Articles. The Ewes being well fed, have plenty of rich Milk, and the Lambs ſucking to their Fill, and being kept quiet, fatten upon it freely. As to the Difference of Seaſon they feel nothing of it; for ſo they be kept warm, it matters not to them whether it come from the Sun, or from their comfortable Shelter.

Having mentioned, in its Place, the folding of Sheep for the Benefit of Land, ariſing from their Dung, we ſhall here add one Caution on that Head, reſpecting the Creature itſelf, and then cloſe this Article.

The Advantage the Land receives from the folding of Sheep is very obvious; but let the Huſbandman take Care that he does not loſe more by the Damage he does his Sheep by this Practice, than he gets by the enriching ſo much of his Land.

There is nothing that tends more to give Sheep the Rot, than this Method of folding them, when due Care is not taken in the doing it.

The Sheep are to be put into theſe Folds at Night, in Summer, but let the Huſbandman take Care only to do it in good Weather; otherwiſe it may coſt him very dear. Let him ſee that they are not turned out in the Morning, till the Sun has been ſome time up; and let him take Care they are driven to a good feeding Place, for otherwiſe, being hungry, they eat any thing: and thus, between cold Nights and bad Food, they get the Rot and periſh.

CHAP. XX.

Of Hogs, their Advantages and Evils.

A GREAT Recommendation of any Animal to the Farmer, is the Cheapneſs of its Food, and this ſets the Hog above almoſt any other in his Eſteem; little is to be bought for that Creature, and he conſumes very little of the Stock of whatever Kind, any thing contenting him that is eatable, though his Appetite is greater than that of any of the Kinds yet mentioned.

If Food is to be raiſed for the Hog, it comes very eaſy; Colcworts, French Beans, and any other of the coarſer Vegetables anſwer the Purpoſe, they grow any where, and are ſown with little Trouble; and the worſt of theſe will fatten the Hog; in which Condition he ſupplies the Family and the Market, to a very good Account.

The Fleſh ſerves the Farmer in a Variety of Forms, and when the more marketable Parts are diſpoſed of, there remains a great deal that anſwers that Purpoſe.

The Refuſe of every Thing ſerves them for Food, as whatever is thrown from the Barn, the Kitchen, or the Dairy. If they be ſuffer'd to run free about, they will, in a great Meaſure provide for themſelves, but this is not a profitable Method, although it may appear a ſaving one. My Huſbandman doubtleſs is acquainted with that good old Obſervation, that all that is ſaved is not got, and it will ſerve for his Inſtruction here; for while they get their Food for nothing by running abroad, they waſte their Fleſh; ſo that what is loſt in their Value, is much more than is gain'd by the ſaving.

Having named the good Qualities of the Hog, it is proper to mention alſo the bad: the Farmer who is about to buy in his Stock, ſhould know at once the Advantages and Diſadvantages attending every Kind, that he may purchaſe accordingly. The Hog is the moſt ravenous of all the Creatures commonly kept about Houſes. They ſpoil and deſtroy more than they eat, if they are not kept in due Bounds, and with a proper Care; and their rooting up the Ground is a very troubleſome and miſchievous Quality. No Creature is more apt to break the Farmers Fences than the Hog; and between this and his tearing up the Ground, and trampling Things to Pieces, the Miſchief he would do if left at large would be endleſs, and all his Value would not pay for it.

Theſe are his ill Qualities, they are therefore to be guarded againſt; and in Proportion as the Farmer is in Danger of being more hurt by them, and has it leſs in his Power to prevent them by a proper Manner of keeping the Creature, by ſo much the more cautious ought he to be in the buying any large Number of this Animal.

The Ways to prevent theſe Accidents, are by managing, or keeping the Hog up. We have ſaid before that in running at large the Hog waſtes his Fleſh, therefore it is always beſt to keep them penn'd up into ſome Court. This is the moſt beneficial not only with Reſpect to their Fleſh, and its Profits, but to the Dung they make in theſe Places, for whatever is thrown to them, that they do not eat, they here trample to Pieces, and being mix'd with their Dung and Urine, it becomes excellent as Manure.

In Places where it is not convenient to keep them thus enclos'd, their rooting up the Ground is prevented by putting Rings into their Noſes; and their breaking Fences in ſome Degree by their being yoak'd.

Theſe are the Remedies for the Evils attending the keeping of Hogs; and the Huſbandman who has already ſeen their good and ill Qualities, will judge upon this according to the Circumſtances of his Farm, whether it be convenient for him to engage in the feeding many of them or not.

CHAP. XXI.

Of the ſeveral Breeds or Kinds of Hogs.

IF upon mature Conſideration any one determines to keep Swine in large Numbers, and with Expectation of a conſiderable Profit, let him firſt be very careful in chuſing his Kind. There are not ſo many diſtinct Breeds in Swine, as there are in Sheep and Oxen, but there is a great deal of Difference between thoſe there are.

The Breeds may be diſtinguiſh'd into three, 1. The wild Hog, which is ſmall, but hardy: it will feed upon leſs than any other, and its Meat, though ſmaller in Quantity, is preferable to that of any other. 2. The common Hog which is larger, longer leg'd, and bigger bon'd than the wild, and affords an excellent Bacon: and, 3. The low big belly'd Hog, which is of late become very common in moſt Parts of England. This lives cheap, is leſs miſchievous than the others, and breeds very faſt. But it is inferior to the common Swine in its Advantages to the Farmer, all Things being conſider'd together.

Of theſe ſeveral Kinds the low Hog is to be choſen by thoſe who live in and about large Towns, to run about the Streets, where it takes Care of itſelf, and does better, being of a quieter Diſpoſition than the others: the Farmer in the Country is to chuſe the common Hog as beſt ſuited to his Purpoſe, being the largeſt in its Growth, bringing forth a ſufficient Number at a Litter, and being eaſily fatted for the Service of his Family, or for the Market.

In ſome particular Counties theſe Creatures thrive better than in others, particularly in Hampshire, Leicestershire and Warwickshire. It will be therefore prudent, if it can be done with Convenience, to buy the Hogs for breed from theſe Places; and let the Purchaſer be very particular on this Occaſion in reſpect of their Shape.

Let them be choſen with long and large Bodies, deep Sides and Bellies, and very thick Thighs; let the Neck be thick, the Noſe ſhort, and the Chine thick and well ſet with large and ſtrong Briſtles.

When the Farmer has taken Care about a proper Kind of Hog for ſtocking his Yard, and underſtands thus how to chuſe them, let him next be careful in ſuiting the Number to the Bigneſs of his Yard, and to the Quantity of the Proviſion he will be able to ſupply them. And in this the Care is, that he do not take in too many; for no Creature breeds faſter than the Hog, and if he does not uſe Moderation in ſetting out, he will be over-run with them.

This great Increaſe depends partly upon the Number the Sow brings forth at a Litter, and partly from the Shortneſs of the Time ſhe goes with young. One of theſe Creatures will have

four

four Litters in a Year, and they will bring from eight to twenty at a Time. So large a Number as the laſt is not common, nor indeed is it natural, for the Creature can bring up no more than ſhe has Teats to ſuckle.

When a Sow brings forth more than ſhe can raiſe, they muſt be put to other Sows, if there be any in the Yard in a proper Condition to ſuckle them; if not, they muſt be deſtroy'd, for there is no raiſing them.

The more Hogs there are in the Yard, the more ravenous they are, for they grow greedy by obſerving the eating of one another; and if there be not ſufficient Food for them at the Time when they give ſuck eſpecially, they will eat up one anothers young, or their own; ſo that of all Creatures in the Stock, the greateſt Care is to be taken with regard to theſe, that more are not taken in than can be fed.

Let the Farmer chuſe out the largeſt and ſtouteſt of his Pigs for the continuing of the Breed; and one Rule of judging early of their Qualities in this Reſpect, is the obſerving which they are that ſuck the foremoſt Teats; for they all aim at this, and the ſtrongeſt get them.

After the proper Number of the beſt and ſtrongeſt Pigs are thus choſen out to be rear'd as Boars and Sows for Breeding, ſuch as are not diſpoſed of while Pigs for the Spit, are to be gelt or ſpay'd according to their Sex. This prodigiouſly increaſes their Fat, eſpecially that of the Females.

Great Quantities of Hogs are rais'd at this Time by the Brewers and Malt Diſtillers, becauſe of the Convenience of their Grains; but of this more need not be ſaid here, the Method being known and eaſy, and at this Time deliver'd down among the Rudiments of thoſe Profeſſions to ſuch as learn them. They are kept clean and well fed, and nothing more is requir'd to their perfect thriving.

There are two different Ways of managing the Fleſh of the Hog for Service; the one for Pork, and the other for Bacon. According to the Choice of theſe, the Age of the Creature is to be different. About nine Months old is the proper Age of the Hog for killing for Pork, and the fineſt Time for Bacon is when they are a Year and half.

As to the Time of their Breeding, the ſtouteſt and beſt Pigs are to be had from Sows of three, four, or five Years old, but they will begin to breed at a Year old, and will very well continue till they are ſeven: the three Years I have nam'd are however the prime. The Age of the Boar is to be conſider'd by thoſe who would keep up a good Breed, as well as that of the Sow, he ſhould not be leſs than two Years old, nor more than five.

The Boar is no Loſs at the End of this Time, he may be ſold for Brawn, if an Opportunity offers; if not, he may be gelt, and will fatten very well: nor does the Operation, though perform'd ſo late, do him any Harm.

A great deal of Prudence is requir'd in the Management of this Creature. An Error any Way in reſpect to their Food, is very prejudicial; for the general Courſe of their Lives it matters not much what it is, but due Care muſt be had about the Quantity. If they are allowed too little, they will be continually ravenous and miſchievous, and if they are fed too plentifully, they will not be healthful. They ſhould be kept in Heart and Strength by moderate feeding, till the Time they are to be fatten'd up for killing; and on this Article depends in every Reſpect, a great Part of the Profit that ſhall ariſe from them to the Owner.

CHAP. XXII.

Of the feeding of Hogs.

AS to the Manner of feeding Hogs, the beſt Method is to keep them for the moſt part in the Yard: their Food there ſhould be Waſh every Morning and Evening; ſuch as Diſh-water with Grounds of Drink, and a few Grains or other Offal: for the reſt of the Day they may be occaſionally ſuffer'd to graze, eſpecially in damp ſedgy Grounds, and the Refuſe of the Garden is to be thrown to them in the Yard. Such of this as they do not eat, they will tread to Pieces, and with their Dung and Urine it will become excellent Manure.

Hogs feed excellently in Woods, and under Hedges in Autumn, when the wild Fruits are ripe and falling, they eat every Kind; Hips, Haws, Sloes, Acorns and Beechmaſt, and theſe are a very natural and excellent Food for them. If Hogs could be fed thus conſtantly, their Fleſh would be ſweeter and better taſted than it is in the common Way of fattening of them; but in ſome Places there is but little of this Food; then it falls out only at one Seaſon of the Year, and the Creature is not well to be truſted. When all Things concur, the Fleſh of a Hog thus fed is excellent: ſome think this Food alone will not give the requir'd Firmneſs to the Fat, but Experience ſhews they are miſtaken.

When Hogs are to be fatted in the Stye, Cleanlyneſs is a very great Article. They muſt alſo be fed often, and not too much ſet before them at a Time, for their ravenous Appetites will lead them to eat more than they can digeſt. Their Food muſt be freſh and good; they muſt have as much freſh and ſweet Water as they chuſe to drink; and be kept quiet. In this Manner they will fatten ſoon and well. Their Fat will be firm, and their Fleſh well taſted.

Nothing anſwers ſo well in all Reſpects for the fattening of Hogs as the Fruit of the wild Trees; they have Air and Exerciſe while they get it; and they live clean; and it is their natural Food: theſe are great Reaſons, but where there is not a Convenience of getting this Food, or the Seaſon of the Year does not ſuit, the Way is to fatten them up altogether in Styes, and this is to be done with Peaſe; or when they happen to be dear, the Meal of offal Corn will anſwer the Purpoſe: theſe are to be mix'd up with Whey or ſkim Milk, or Milk and Water, and the Creature will never fail to fatten upon any of them.

It will take about a Month to fatten a Hog in this Way, ſuppoſing him to have been in that

midling Condition before, which we have recommended for the Sake of his Health. Peaſe, when they are to be had, are to be prefer'd to the other Foods; and there is ſuch an Opinion of their Effect in giving Firmneſs, and a clean Taſte to the Fat of the Bacon; that in Places, or at Times when they happen to be dear, although the Hog be fatted up with the other Things, they generally give him a good Quantity of Peaſe the laſt Week.

Hogs will ravenouſly eat the Buds of many Trees, particularly the Aſh and Sycamore, and it is a Practice in ſome Places to beat down Sycamore Leaves for their Food, upon which they will fatten.

Grains fatten them very quickly, and often when theſe Creatures will not thrive with any other Food, theſe will bring them to themſelves, and they will afterwards fatten upon any Thing.

The Way in which Hogs are fatted in many Places, for the Service of the Navy, is excellent; and when there are Conveniencies for it, ſhould be follow'd by every Farmer who deals in theſe Creatures. They take in a Piece of Ground by the Side of a running Water, hedging in alſo ſome Part of the Water that there may be a Place for the Hogs to drink without Danger of their Eſcape. They ſtack up a Quantity of Beans and Peaſe in this incloſed Piece of Ground, and turn in as many Hogs as the Quantity of Food will fatten. They let them here live at their Eaſe and Liberty one among another, cutting down the Stacks as they are wanted. Thus having Plenty of Food and Water, and Room and Quiet, they fatten excellently.

As the Hog is a Creature often apt to waſte its Food if too much be given at a Time, they have a very good Contrivance in ſome Parts of Oxfordshire to prevent this, and at the ſame Time to ſave the Trouble of that conſtant Attendance, which is requir'd in feeding them with ſmall Quantities at a Time. They do it in this Manner. They place over the Stye a Veſſel like the Hopper of a Mill, and into this put as much Beans or Peaſe, or other dry Food, as will fatten ſuch a Number of Hogs. From this there comes a large ſquare Pipe down half Way of the Stye, thro' which the Food continually deſcends out of the Hopper. This Pipe terminates at that Diſtance in ſix ſmaller Pipes, each of which ends in a ſmall Trough, that is no bigger than juſt to admit the Noſe of the Hog; and they come all of them with their Ends ſo near the Bottom, that there is never above a Handful of the Food at a Time in each Trough. When this is taken away by the eating of the Hog, there follows ſo much more. This prevents their waſting any Part of the Meat, at the ſame Time that they have a conſtant Supply: and if it happen from the Convenience of the Place, that a ſmall Current of Water can be brought through the Stye, they will in this Manner be fatted with leſs Trouble, than in the Way already mention'd of ſtacking the Beans and Peaſe for their Service.

The Inconvenience from Hogs rooting up the Ground, has been mention'd already; and the common Method of preventing it, which is by putting a Ring in their Noſe; but as this is often ineffectual, and a great deal of Miſchief is ſometimes done very unexpectedly by theſe Creatures, we ſhall propoſe, to the Imitation of the Farmer in general, a Method much more ſecure, which has been long practiſed in Staffordshire, and ſome of the neighbouring Counties, although it has not got into Uſe in all Parts of the Kingdom.

Inſtead of the Ring they uſe a forked Iron, arm'd at each Point with a Fin like the half of an Arrow-Head. This being thruſt through the Edge of the Hog's Noſe, cannot be got back, and they cap the Bottom or ſquare Part of the Fork that lies upon the Noſe with a long and hollow Ring, which turns round upon it. So that the Creature can never take hold enough to turn up the Earth. This is a Contrivance very eaſy, and it ſhews its own Uſe. The Damage Hogs often do by rooting up the Ground is ſufficiently known; and many have found how unfit the common Method by Rings is to prevent it. This will never fail perfectly to anſwer its Intent; and ought therefore to be univerſal.

The Method of feeding Hogs on Clover has been mention'd occaſionally in another Place, when we were ſpeaking of the Dung of that Animal as a Manure; and ſomething farther may be properly added here. Clover is an excellent Food for the Hog, but it is beſt not to make it the only Food, for it is apt to give a Yellowneſs to the Fleſh, which hurts it in the Market. The beſt Method of giving Hogs Clover is, at the ſame Time that they are feeding at other Hours of the Day on other Things. Thus let them be turn'd out of the Stye without their Breakfaſt of Waſh in the Morning, that they may have a good Stomach for the Clover; and at the right Seaſon be driven into the Field with the Horn'd Cattle. At Evening let them be brought home, and fed with Waſh mix'd with Grains or Corn, or let them have inſtead of the Waſh, a great deal of ſkim Milk or Whey. This is the Manner in which Hogs may be fed to the greateſt Advantage upon Clover: and it is a very good Method of managing them.

Bran and Pollard fatten Hogs very ſpeedily, but the Fleſh is not ſo firm: nothing for this Purpoſe anſwers like the Pea or Bean; a great Variety of Foods might be mention'd for a Creature that will eat any Thing, but there are none of them come up to theſe, which are natural to the Animal.

The Diſtillers Waſh and Grains feed them up quickly, but there is a great Difference between the Bacon and Pork fatted by that Means, and ſuch as is fed on the natural Fruits of Trees or Pulſe, ſuch as have been before recommended.

The ſame Kind of Food is alſo excellent, given properly, and in due Quantity for the feeding of Pigs at their firſt weaning, the beſt Food is ſkim Milk, Whey, and the artificial Graſſes. After a Week or ten Days, it will be proper to add Bran or Grains to the Whey or Milk; and ſoon after this they may have Peaſe and Beans in Moderation, and this will increaſe their Growth, and make their Fleſh better. After this, if they have been pig'd in an early Seaſon,

they

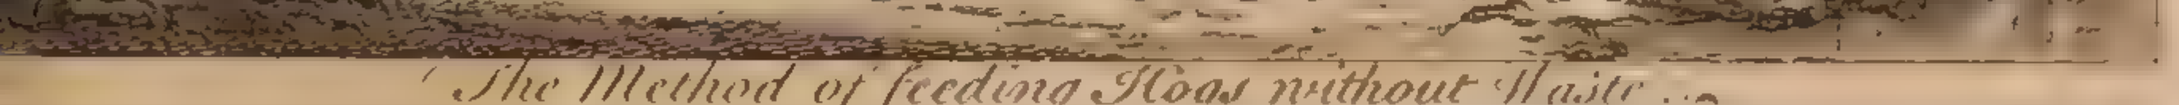
The Method of feeding Hogs without Waste.



Elevation and Section of the Building for breeding of Rabbits.

they will come in for a Share of the Stubbling and Beechmaſt which will at once raiſe them beyond Expectation.

A great deal of Advantage in this Reſpect is owing to the Seaſon of their being pig'd; the Spring, or early in Summer, is the beſt Time for thoſe that are intended to be brought up; thoſe that are farrow'd near Winter, if ever ſo much Care is taken of them, growing ſlowly they are often ſtunted in their Growth; and they are always more ſubject to Diſeaſes than thoſe which come at a more favourable Time.

CHAP. XXIII.

Of Goats.

THE Goat is not to be ſet upon an Equality with the Sheep or Swine, in its Value in any Reſpect; but there is an Advantage attending it which none of the others have, and which ought to recommend it to the Conſideration of all who are ſituated ſo as to enjoy its Benefit; this is, that it will live where neither Ox, Sheep, or even Hog can. In ſuch Places it does not ſtand in Competition with thoſe ſeveral Kinds, for they cannot be fed there; but for this very Reaſon, the Goat ſhould be bred in thoſe Places, for the Profit of this Creature is ſomething; and it is in that Caſe the only Kind that can be had.

The Goat will feed in common Paſtures, but there it is not worth while to breed or ſuffer them, for Sheep of one Kind or other will live on them according to their Natures; and the very worſt Kind of thoſe are greatly preferable to the Goat in Profit. Beſide, the Goat is more apt to crop the young Shoots of Trees and Shrubs than any other Animal whatſoever, and in this Reſpect alone, would do more Miſchief than he was worth.

Theſe are ſufficient Reaſons againſt breeding this Creature in common Grounds, but where there is hilly, barren and uſeleſs Land in any Quantity, there 'tis every one's Intereſt to breed this Creature, for it will walk at its Eaſe where any other Animal would break its Neck, and will feed very well where any other Kind would ſtarve.

The natural Soil and Situation for the Goat is a barren, rocky, and craggy Mountain. Theſe Places, even the worſt of them, produce ſome Briars, and other ſmall Shrubs, and upon the Shoots of theſe the Goats browſe with the greateſt Satisfaction imaginable.

In general the Food of Goats is ſuch, as is of no Uſe to any other Creature; and they are to be bred with very little Care or Trouble. For theſe Reaſons I would adviſe every Huſbandman who has in his Poſſeſſion this barren, buſhy, and rocky high Ground, to keep them: and for his Inſtruction to make the greateſt Profit by them, I ſhall lay down ſome Obſervations which I have received from a very worthy Correſpondent upon the Borders of WALES, where there are a great Quantity of them kept to conſiderable Profit.

There is leſs Difference in Goats then among moſt other Kinds, yet for the Farmer who intends to bring them to a new Place, the following Conſiderations ſhould be obſerved in the Choice.

The beſt Goats are thoſe which are ſtrongeſt limb'd, and largeſt bodied, therefore let them be choſen for Breed, big made in every Part, and cover'd with a deep and ſtiff Hair. Let their Joints be firm and ſtrait, the Neck ſhort and thick, and the Head ſmall and ſlender, with full and large Eyes, and long and ſtout Horns. The Colour is not material, nor certain, but in general the black Goat is the ſtouteſt, and his long Beard is a Sign of a good Kind; the py'd Goats are ſuppoſed to bring forth the fineſt and beſt taſted Kids, but this is not certain or unalterable.

The Goats being thus choſen, the next Care is the putting them together for Breed. No Creature is ſo ready for copulating. The Seaſon when the young will be beſt bred up, is ſuch as comes from their being put together toward the Middle of Winter. This is the Time at which the Huſbandman who intends to raiſe a good Breed, ſhould put them to one another; and to this Purpoſe the he Goat ſhould be from two to five Years old: he is beſt if about three or four; and the ſhe four, five or ſix. This is the Time of Life at which they are found to breed the beſt and ſtouteſt young ones, for the he Goat wears himſelf out by his frequent Copulation, and is enfeebled by Age at ſix Years old; after which Time his Young are poor, and ſeldom come to any Thing.

The ſhe Goat is ſeldom troubled with Diſtempers, and is a very free Breeder; they will very well bring forth twice a Year, and they have ſometimes two, and ſometimes three Kids at once.

The Goats ſhould be kept in Herds or ſmall Flocks; and though they are very hardy, yet it will be a great Advantage to them if they have Shade in Summer, and Shelter in Winter. But this laſt muſt not be carried too far; if they be houſed in the hardeſt Time of the Winter, as is done in ſome Places, they ſhould have no Litter; for that will make them too hot: they are uſed to Hardſhips in their natural Way of living, and nothing is ſo likely to do them Miſchief as too much Care and Tenderneſs. Cleanlyneſs is a great Article when they are houſed, for as they are uſed to ſweet Air, and are in themſelves very rank; if they are kept hot and frowzy, they fall into Diſorders.

Nothing will require a ſtricter Care in the Farmer's Hands who breeds Goats, than the defending his Trees from them, for they will certainly deſtroy the young and new planted ones; and the oldeſt will not eſcape.

It is enough for the Defence of Trees againſt other Animals, to train them up ſo that the Branches ſhall be above their Reach from the Ground, but this is no Defence againſt the Goat; for that Creature will climb the old Trees, particularly the Elm, of whoſe young Shoots it is very fond, and will browze for Days together among the young Branches.

For this Reaſon as the barren and rocky Grounds before mention'd, are fit Places for them, they ſhould be confined to theſe alone.

Otherwiſe they will ſoon do more Miſchief than they are worth. This keeping them in due Bounds however, is not difficult; and there are a great many Places in England, where a very conſiderable Profit might be made by breeding them.

The Advantages the Huſbandman receives from the Goat are of four Kinds. The Milk, the Fleſh of the Kid, the Skin, and the Hair: but of theſe the two latter are leſs regarded.

The Hair is, in ſome Places, us'd for twiſting into Ropes, and has this Preference above all other Kinds, that it will never rot in Water. In ſome Places alſo Goat's Hair is wrought into a Kind of Cloth for Apparel.

The Skin is capable of being dreſs'd into a very good Kind of Leather; and it is uſed for this Purpoſe in ſome Places, though altogether neglected in others. Goats Milk is of the Nature of Aſſes Milk, an excellent Reſtorative in Conſumptions, and for decayed Conſtitutions; and in ſome Counties they make a very good Kind of Cheeſe from it: in other Places, where the Stock conſiſts partly of Goats, and partly of Cows, the latter of which the Huſbandman cannot keep either of a very good Kind, or in any great Number, becauſe of the Barrenneſs of his Land, they mix the Goats Milk and Cows Milk together, and this Way it yields a very good Kind of Cheeſe, and that in a large Quantity, according to the common Way of making. This is the Practice I ſhould adviſe to the Farmer who keeps Goats: for there is ſcarce any Place where he may not upon the better Pieces of his Ground, keep ſome Cows, and the Goat's Milk anſwers much better, and is managed much more eaſily for Cheeſe in this Mixture, than when People are reduced to uſe it alone.

The Fleſh of the Goat is very rank, and even unwholeſome, as well as unpleaſant; but Kid is a fine Meat, it is very little inferior to Veniſon; and as the Kid is ſo eaſily had, and rear'd with ſo little Trouble, were there no other Reaſon for keeping of Goats, this were ſufficient. People that are delicate about the Fleſh, are at the Pains to rear Kids for the Table, in the ſame Manner as we have directed already for Lambs; but this is not worth while, for with the leaſt Care imaginable they grow to an excellent Condition, as they run wild after the Dam.

CHAP. XXIV.

Of the Rabbit in general.

THE Rabbit is a ſmall Animal, and may appear of ſmall Conſequence after the Kinds already named for the Farmer's Breeding, yet this is very well worth his regarding, as a Part of his Stock. It has the Recommendation of the Goat, that it will thrive where nothing elſe can live; and the ſame Advantage as the Hog, in the great Encreaſe by young.

Both the Buck and Doe Rabbit are eager for Copulation, and they muſt not be reſtrain'd. The Does go but a Month with young; and as ſoon as they have brought forth, they are ready to copulate again. When they run wild they get together in a very little Time; and when they are kept tame and ſeparate, they muſt be put together ſoon after the bringing forth, otherwiſe the Doe grows ſullen, and will take little or no Care of her young ones.

The Rabbit is diſtinguiſhed into two Kinds, the wild and the tame. Theſe are kept in a diſtinct Manner; the wild running looſe, and burrowing themſelves Holes in the Ground, and the tame being kept in Houſes, Huts, or Boxes.

Both Kinds yield a very large Profit, though under different Management. The wild Rabbit breeds faſtly and freely in Warrens, or other Places where there is Room and a free Air. They will thrive upon the pooreſt and barreneſt, gravelly, ſtony, or ſandy Soils; by ſtony we mean ſuch as are full of ſmall Stones, not the rocky, for in theſe laſt they cannot burrow. In theſe Sort of Grounds the Farmer will find great Advantage from the breeding of Rabbits, either altogether or occaſionally: for in the latter Way they improve theſe barren Lands extreamly, by their Dung and Urine, and render the worſt of them fit for raiſing good Crops of Rye; and ſuch as are but a little better, for the other Kinds of Corn.

The Diſtinction between wild and tame Rabbits is not founded in Nature, but on our own Practice; for the wild Kinds may be as well kept tame as the others. They are uſed to a Kind of Impriſonment in their Holes, and for that Reaſon they bear Confinement better than moſt other Creatures.

CHAP. XXV.

Of the Wild Rabbit.

AS to the wild Kind there is properly but one Breed of them, and all the Direction that is needful in the Choice is, that ſuch as are taken to begin a Stock, be large and big bodied, with a good deep Fur that hangs faſt upon their Backs, and with ſtout Limbs. The Huſbandman that has waſte Ground in his Hands, that is fenced well, and not with live Hedges, ſhould never omit this Part of his Stock, for the very worſt of his Ground will do, and the Advantage he receives from them will be very great.

A ſmall Number is ſufficient to be firſt turn'd in, for of all Creatures uſeful to Mankind, they are the greateſt Breeders.

Experience ſhews that the wild Rabbit ſucceeds better in ſome Places than others; the young growing up much quicker, and the Fleſh being finer and better taſted. The Reaſon of this is to be ſearch'd in the Soil and the Produce; and this may teach the Huſbandman on which of ſuch Grounds as ſeem proper, it will be moſt to his Benefit to breed them.

In general, the ſhorter and ſcantyer the Graſs, the better is the Taſte of the Rabbit. The dryer the Ground the better they ſucceed, where there is much Water they never are well flavour'd.

Of all Creatures, Water is the leaſt neceſſary to the Rabbit, for we ſee the tame ones will live very well altogether without it, on moiſt Food.

Where

Where the Soil is dryeſt, the Air fineſt, and the Water that there is in the Way is running and clear, there the Rabbits may reaſonably be expected to ſucceed beſt. Damp Ground, and ſtanding Waters being the greateſt Diſadvantages to this Creature.

As I have obſerved that the common wild Rabbit will very freely be kept tame; ſo it has been found, many Years ſince, that thoſe which we uſually underſtand as tame Rabbits, will live very well wild, eſpecially the hardier Kinds. This is a Conſideration of ſome Conſequence, becauſe there is one of the tame Kinds that is, in every Reſpect, better than the common wild one. This is that which is known by the Name of the Silver-hair'd Rabbit. It will live and thrive as well wild as the common Sort; and it is always better taſted and fairer to the Eye, ſo that it brings a larger Price. The Skin alſo is of much more Value, and the Demand for it among the Furriers is conſtant and certain.

For theſe Reaſons it is, in many Caſes, adviſeable to breed this Kind wild inſtead of the other: but though it often is ſo, it is not always. This, though as hardy as the other, requires a better Supply of Food, and is poor, and of little Value upon thoſe barren and heathy Lands, on which the common wild Rabbit ſucceeds very well.

The proper Place for this Kind is a Park, where it may run at Liberty among the Deer and other Cattle, and where there is good Graſs, though not rank, upon the Ground: the other is the proper Kind for the miſerableſt and pooreſt Lands.

CHAP. XXVI.

Of the tame Rabbit.

TAME Rabbits are diſtinguiſhed into ſeveral Kinds, according to their Colours and other accidental Diſtinctions; but the Differences are not great, nor is there any material Point of Profit attending the Choice of one or the other Sort.

The Silver-hair'd Rabbit laſt-named, is a very good and profitable Kind to be kept tame, becauſe of the Advantage of the Skin. The DUTCH Rabbit is a much larger Kind, and is very good for the Table, but the Skin is of leſs Value. The moſt beautiful, when kept cleanly, is the white long-hair'd Rabbit, this is, by ſome, called the TURKEY Rabbit, from the Place from whence we firſt had it; and by others the Shagge Rabbit, from the Length of its Hair. This is a very good Kind to breed tame alſo, but if not kept very clean, it is ſubject to a Diſorder not unlike what Doctors call the Plica Polonica; the Hair growing together in Clots and Cakes, and this often in ſuch a Manner, that Blood Veſſels from the Skin run up amongſt the Clots, and they will bleed on being cut off.

It is not very material which of theſe, or of the ſeveral other Kinds that it is a Cuſtom to breed at this Time, the Farmer chuſes; for, with proper Management, any of them will turn to very good Account; but which ever Sort it be, let him take a more ſtrict and critical Care in the Choice, than he has been directed to do in thoſe which are to run wild, for a great deal more depends upon it in this Kind, than in thoſe. The Skin here is of much Conſequence, and the Diſtinctions in this are nice, and never enough to be regarded in the Choice for Breed.

In the Silver-hair'd Rabbit for Inſtance, let the Huſbandman take Care to chuſe his Buck of the true Kind and Colour, for on this, more than on the Doe, will depend the Value of the Breed. Let the Fur be thick, deep, ſmooth, and gloſſy; and let the Ground Colour be black, with a moderate Quantity of white or ſilvery Hair. It is proper to chuſe them rather too dark, for breeding, becauſe the Colour in the young is more apt to grow paler than deeper; and a Silver Skin that is too dark, always will bring a better Price than one that is too light.

In the ſame Manner let the Fur of the ſeveral other Kinds be examined, when they are choſen for breeding; for the reſt of the Directions already given, for the Choice of the wild, hold good here: the largeſt and beſt ſhaped being to be fix'd upon. In the ſame Manner as theſe Rabbits were firſt choſen, let them be pick'd out from time to time for keeping to preſerve the Breed; for upon this will depend a great Part of the Advantage.

The Farmer having thus ſelected his Stock of theſe little Animals, is to take his Choice of the ſeveral Methods which are in Uſe for the breeding and keeping of them. Theſe are many, and among them ſome allow more and ſome leſs Liberty to the Animals in general, ſuch as allow moſt Freedom, even in this Way, and moſt Air, are beſt, for though the Rabbit will bear Confinement very well, yet it will thrive beſt where that is leaſt ſtrict.

Cleanlyneſs alſo is a very great Article in the breeding of theſe, as well as other Creatures, and where the Confinement is leaſt ſtrict, there is naturally leaſt Foulneſs. The Dung and Urine of the Rabbit have a very diſagreeable and rank Smell; and nothing prejudices the Creature more than being kept naſty with theſe about it.

The general Way of keeping tame Rabbits is in a Kind of Boxes made for this Purpoſe: others keep them in Pits; but it would be a much better Way to keep them in Buildings made for that Purpoſe. This might be done at a ſmall Expence, and would anſwer very well: for it would be cleanlier and more wholeſome than any other Way. The Boxes are too ſmall, and therefore are apt to grow naſty, and the Pits are liable to be damp, which, as we have obſerved already, is one of the worſt Things that can happen in a Place where Rabbits are to breed.

The Boxes, for ſuch as prefer them, ſhould be made of thin Wainſcot, and divided into larger and ſmaller Rooms, two for each Rabbit. One of theſe ſhould be for eating, and the other for lodging and bringing forth the young. That for eating ſhould be the larger, and ſhould have a Grate before it for Light, and the ſmaller ſhould be entirely dark. Before both there muſt be plac'd a Trough, with the Food; and thus the Creature will live, thrive, breed, and fatten: but there wants free Air, and it is very difficult to keep

keep them cleanly, ſo that although this Method may do, the others are ſure to anſwer better, when they are managed properly.

Thoſe who uſe this Method by Boxes, ſet them one above another, in ſo many Stories; and keep the Bucks by themſelves, and the Does by themſelves; unleſs it be ſuch Does as have not bred; and with thoſe they lodge a Buck in the ſame Box. The common Size of theſe Boxes is two Foot long, the ſame in Breadth, and a Foot high. It is ſurprizing to ſee ſo large a Creature as a Rabbit live ſo well as it does in this ſmall Compaſs; but it will always do better when it has more Room.

The Method of keeping them in Pits is preferable, and is thus. A dry Soil is to be fix'd upon for this Purpoſe, and the Pit is to be dug ſeven Foot deep, and of a Bigneſs proportioned to the Number intended to be kept in it. This muſt be wall'd up on the Inſide, only leaving Spaces for them to make their Burrows. A ſandy Soil, not too deſtitute of other Earth, will anſwer for the Purpoſe of theſe Pits, better than any other. At one End an hollow Place is to be made for the Buck to reſt in, he muſt be chain'd to a Stump, and have Room only to go to the Rack where the Food is placed in theſe Pits, and thence to his Den to reſt. At the other Parts of the Pit, out of the Reach of the Buck, are to be the Places left for the Does to make their Stops or Burrows. The Rack is to be placed near the Middle of the Pit, between the Buck and Does, he being on one Side by himſelf, and they on the other.

Three Does may very well be kept in the ſame Pit with one Buck, and the Pit for this Purpoſe ſhould be about ten Foot ſquare. Some make them larger, and keep more Bucks than one, but it is a better Practice to make more of them, only allowing one Buck and two or three Does to each.

This will naturally appear to thoſe who are not acquainted with theſe Things, a large Proviſion for three or four Rabbits, and a great Expence for ſo few and ſmall Animals; but thoſe who have kept theſe Creatures know that it very well anſwers the Expence. Provided the Pit be dry they live more comfortably by much in it, than in the other Way of Boxes; and the Produce is ſo great that one Buck and three Does will bring a hundred and fifty, two hundred or more young ones in a Year.

The young are to be left under the Care of the Dam, till they are about a Month old, and they are then to be taken from her, either for Sale or the Table; or if there be no Demand either of theſe Ways for them, they muſt be put into ſome Pit, or other Place made for that Purpoſe.

The ſame Practice is to be obſerved in removing the young, if they are kept in Boxes, or whatever other Way. In whatever Manner the old ones are kept, when they have brought forth a ſecond Brood, the firſt is to be taken away, and rear'd up elſe-where. The common Way in this Caſe is, to remove them to other Boxes, keeping thoſe of ſeveral Broods of about the ſame Age together: and thus they are to be treated in the other Way, either rearing them in another Pit, or in any Manner that is convenient, only allowing them ſome Room and Air, the more of both the better.

The Reaſon of chaining up the Buck Rabbit in the Pit, and of keeping him in a ſeparate Box in the other Way, is his miſchievous Diſpoſition, for he will kill all the young ones. This the Does are themſelves ſo ſenſible of, that they, in their natural wild Life, hide the young ones, and cloſe up their Holes, that the Buck may not find them.

The two great Requiſites in theſe Pits are Warmth and Dryneſs: their Depth, unleſs the Ground be very favourable, making them ſubject both to damp and cold, in either of which Caſes the Rabbits will not breed well.

The moſt profitable Time of their Breeding is in the Depth of Winter; and they will never breed at this Seaſon, at leaſt not ſucceſsfully, unleſs they be kept dry and warm.

CHAP. XXVII.

A profitable Method of keeping tame Rabbits.

IT is from the Danger of the Cold and Damp in Pits, and becauſe of the want of Air in Boxes, that I have been led to think of ſuch other Methods as may give Rabbits the Advantage of both in a fit Degree, and yet keep them in ſuch an eaſy and ready Way, that they might be always at hand, eaſily fed, tended, and looked after in every Reſpect, and yet have Warmth and Freedom.

To obtain theſe ſeveral Advantages, by means of which tame Rabbits of the beſt Kinds would be kept in the greateſt Perfection of Health and Beauty, and to the greateſt Advantage of Breeding, let the Huſbandman erect a Building purpoſely for them.

Having choſen his Rabbits for Breed, let them fix upon a proper Spot of Ground for his Edifice, and draw the Plan of it of ſuch Extent as to contain conveniently the Number he ſhall think proper to keep.

Let the Soil on which he builds this Place, be of a dry loamy Kind, with a large Proportion of Sand in it; for this is the Sort of Earth the Rabbit loves beſt, and in which it is always moſt healthy.

Let the Building be ſquare, and run up of Wood in a ſlight but yet a tight Manner; and let there be a Kind of Cloſet carry'd up at one End.

In each Corner of this Square let there be a Den made for a Buck Rabbit, and a ſmall Poſt driven in, to which to faſten him by a Chain, in the ſame Manner as in the Pit. At ſome ſmall Diſtance from the Corners, let there be Racks ſet up for Food, which ſhall be within the Reach of the Bucks, and one or two others in the Middle.

When the Houſe is thus prepar'd, let the Bucks be chain'd in their Places, and the Does turned in. They will all live much more comfortably in this Houſe than in the Pits; and at the Times of taking away their young, let them be put into the ſmaller Rooms or Cloſets, pre-

pared for that Purpoſe, where they will live and thrive very comfortably. A Building of this Kind will coſt little, and the Profit ariſing from the Rabbits will be much greater than in any other Way, becauſe they will breed freely throughout the Winter; and neither the old nor the young will be ſubject to Diſeaſes. Both the old and the young will be, in this Manner alſo, defended better againſt Vermin than by any other Way whatſoever.

The feeding of the Rabbit is an Article of great Conſequence, with Regard to its Health and Encreaſe, and it is leſs underſtood than moſt Things of the like Kind. Some feed them in a Manner entirely with wet Meat, others almoſt altogether with dry: now both theſe Methods are wrong. From what I have ſeen and try'd, a Mixture, or Diverſity of Food, keeps them better in Health and Vigour, and occaſions their breeding faſter, and more ſucceſsfully than any one Kind.

The dry Meat of the Rabbit is Hay, Oats, and Bran. Their moiſt or wet Food is freſh Herbage, or Roots, of almoſt any Kind, which they will eat with the greateſt Eagerneſs, as Coleworts, Parſley, and others, from the Gardens; and Sow-thiſtles, Mallows, and the like, from the Fields. Now theſe I would adviſe the Huſbandman to give them interchangeably; always obſerving this Caution, that when he gives his Rabbits dry Meat, he muſt ſet them Water; and that when they have the freſh or moiſt Meat, they have no Occaſion for any; the Juices of thoſe Leaves and Herbs ſupplying them with a ſufficient Humidity.

It is a common Cuſtom with many to cut up the freſh Food for their Rabbits from under an Hedge, taking every kind of Herb that offers, ſo it be young, and the Rabbit will eat almoſt any; but in this ſome Caution is neceſſary, for the Herb Hemlock is very common under Hedges, and it is poiſonous; the Rabbit will eat it greedily, but it dies by the Effect.

The Hay that is given to Rabbits muſt be the fineſt, ſweeteſt, and ſhorteſt that can be got. Nor let any one grudge the Expence, for they eat but little, ſo that the Amount is ſcarce worth Conſideration.

This is the beſt and healthieſt Food of all others for Rabbits, and ſhould be their ſtandard Diet, but about once in five Days they ſhould have the freſh Herbs, which cool and ſcour them. And by this Management they will be kept healthful and vigorous; always ready for breeding, and their young will be luſty, ſtrong, and thriving.

Among the other Food of the Rabbit ſhould be mentioned Grains: this is of a middle Nature between the moiſt and dry Food; and is a very cheap Diet; but it is not wholeſome, and therefore is dearer in the End. The Rabbits will ſeem to thrive upon it, but there is no Food whatſoever that makes them ſo liable to Diſeaſes.

In general, the Advantage of their dry Meat is, that it prevents Diſeaſes: and thoſe who commonly keep them upon freſh and moiſt Food, as many do, giving them Carrots and other eatable Roots among it, would do well to change it for dry Meat in wet Weather: for moiſt Food is the great Cauſe of theſe Creatures having the Rot, and they are moſt of all ſubject to this in damp Seaſons.

BOOK V. PART II.

Of FOWLS.

CHAP. XXVIII.

Of the Cock and Hen, their Kinds and Choice.

WE come now to the Conſideration of Animals of ſmaller Size, and leſs Advantage than thoſe ſeveral capital Articles of the Farmer's Stock treated of in the firſt Chapters of the preceeding Book; yet not to be neglected. We are led by the Conſideration of the little Animal, laſt named among the Beaſts, to the Creatures of the winged Kind, among which we have begun not with the largeſt Sort, but the moſt uſeful. We have ſeen what conſiderable Profit may ariſe from the Rabbit well managed; and we ſhall ſee here that the Hen, when conſidered with reſpect to her Eggs and Chickens, not to mention her own Body, and the Feathers, affords an Article, though ſmall in Compariſon of ſome among the preceeding, yet very worthy of the Farmer's careful Regard.

Though the Profits ariſing from the Hen and her Kind are ſmall, in Proportion to thoſe of the Ox or Sheep, yet they come eaſier. There is leſs Trouble and Expence in theſe Creatures, even than in the Rabbits. Indeed they in a Manner take Care of themſelves; feeding at the beſt upon the Scatterings of the Barn, with little Aſſiſtance; and maintaining themſelves even where there is not this Help, by their own Care with very little Help.

Fowls are therefore a Stock the pooreſt may keep, and ſuch as the richeſt need not to neglect; they are univerſal, and they very well deſerve to be ſo; and are a Comfort to the Peaſant, while they add their Profit, though ſmall not inconſiderable, to the general Purſe of the wealthy Farmer.

The Huſbandman is therefore to provide himſelf with Cocks and Hens as a material Part of his Stock, and he need not be afraid of overdoing in this Article; for theſe are not like thoſe Creatures, Numbers of which require great Attendance, and rich Paſturage: a very conſiderable Quantity of theſe will provide for themſelves in his Yard, and at the Barn Door, for the greateſt Part of the Year, without doing him any

any Damage, and will be ſupported during the Remainder, at a very ſmall Expence.

The Advantages they afford in Return for this are very conſiderable in their Kind, when the Number is large; and they are in a Manner continual: they are a conſtant Supply for the Proviſion of his Family; and as conſtant for the Market; where, according to their Management, they afford a larger or ſmaller Price.

The Value of every Thing riſes in Proportion to the Demand there is for it, and on this will depend the particular Directions that are to be given to the Farmer in this Article. The great Demand for Fowls is in large Towns, therefore the careful Provider ought to proportion the Quantity of theſe he keeps to his Situation. If he live in a lone Place, it will not be worth his while to keep more than will ſerve for his own Family's Supply, and for a few of his Neighbours who may purchaſe of him: but if he be ſituated near a Market Town, eſpecially if within a due Diſtance of London, he may ſtock himſelf as largely as he pleaſes; and the greater Number the more the Profit; for there is there a conſtant and good Market throughout the whole Year, for one Kind or other in this Way, either Eggs, Pullets, Chickens, Capons, going off at a good Price the whole Year.

Additionally to this, which is the greater Conſideration, he has the leſſer Article of their Feathers; and he has alſo the Dung, which is very rich, as has been already ſhewn in its proper Place.

The Huſbandman therefore by this Conſideration, will be led to the fixing upon a proper Number of this Kind of Stock, and after that he is to acquaint himſelf with the Choice before he makes his Purchaſe. A great deal depends upon the firſt Choice in all theſe Caſes: the whole Brood to come is to be of the ſame Kind with theſe, which are the general Parents.

The Induſtry and Curioſity of thoſe who breed Poultry of this Species for their Pleaſure or Profit, have of late Years greatly multiplied what are called the Breeds: but theſe Differences are not ſo great as many imagine. They ariſe from ſmall Diſtinctions, and will ſometimes go off in the Continuance. Between the Darking Fowl, and the little Bantam Breed, there are many Degrees in Bigneſs; and the Game Breed is altogether diſtinct from all theſe; anſwering the Purpoſes of the Sportſman, not of the Farmer.

Among the ſeveral Breeds I would adviſe my Huſbandman to chuſe, not fixing himſelf to one in particular according to what he ſuppoſes to be its Value above the reſt, but conſidering which will beſt anſwer the Demand he is like to have for the Produce. In ſome Meaſure, indeed, he is to be guided in this by the Circumſtances of his Farm; as in the Choice of his Oxen and Sheep, by the Richneſs of his Paſtures. He who has a good Barn Door, and a rich Yard, will be able to keep a proper Quantity of the largeſt Breed of theſe Fowls in Health and Vigour: the common or ſmaller Kind will ſucceed beſt with the Peaſant or the poorer Farmer, for they will ſupport themſelves by running about the Roads and Hedges, in a great Meaſure; eating Inſects, Seeds, and whatſoever can afford a living Creature Nouriſhment.

Thus upon theſe two Conſiderations of the Food and the Demand, taken together, the Huſbandman, of whatſoever Rank, will be able to know which of thoſe ſeveral Breeds that are now ſo common in all Places, it will be his Intereſt to take.

Whichſoever Kind he fixes on, let him obſerve theſe Marks of Goodneſs in the particular Fowls he buys, and guide himſelf by them in the Choice.

Let the Cock be large for his Kind, full bodied, well ſhaped, and lively: the Cock is naturally an upright, ſtately, and majeſtick Bird; and when he appears without theſe Characters, 'tis a Proof that ſomething is amiſs. The Cock that does not ſtrut, is not fit for the Father of a Brood. He ſhould be long in the Body, and thick in the Garth. His Neck ſhould be long and naturally arch'd, free in its Motions, and well cover'd with Feathers. His Comb and Watles ſhould be large, and of a bright red; his Eyes full and ſprightly, and their Colour anſwerable to that of his Feathers, which is a great Beauty in the Cock, and a Mark of a right and true Breed. His Beak ſhould be ſtrong and hooked, his Legs ſtout and ſturdy; his Spurs long and ſharp, and his Claws ſhort and ſtrong. Theſe are the Marks of a good Cock, of whatſoever Breed. Some have made a great deal of the Colour, but the two beſt are the red and the white, of which the red is fitteſt for a ſtout breed, and the white for a more delicate.

In the Choice of the Hen, the ſame general Marks are to be obſerv'd as in the Cock, only her whole Aſpect ſhould be mild as the Cocks is ſturdy. She ſhould be lively and well colour'd; her Claws ſhort and ſtrong; but if ſhe want the hinder Claws, it is ſo much the better. They often breaking the Eggs in her ſitting.

When the Cocks and Hens are thus choſen, let them be well obſerv'd as ſoon as they are put into the Ground, for if any Thing be amiſs in them, that is the Time to change; and it is much better to ſell the bad again, and buy others, than to ſit down content with ſuch as are not of the beſt Kinds in every Reſpect; the Loſs attending this can be little, and is for once; but the Diſadvantage of having a bad Kind is great and continual.

The Cock ſhould be lively, buſy and noiſy: he ſhould be often crowing; and from time to time ſcratching up the Ground to turn up Worms and other Food for the Hens. The Hens ſhould be lively, but quiet; a crowing Hen is as much to be rejected as a dumb Cock: for theſe are found by Experience, neither to lay any Quantity of Eggs, nor to ſit well.

Now if any of theſe Faults appear in the Fowls that are bought for the Breeders of a Stock, let ſuch as have them be changed; and this done over and over again till ſuch as are in every Reſpect right, are fixed upon.

The Proportions of the two Sexes is about one to ten: a ſingle Cock will ſerve twelve or fourteen Hens; but the moſt profitable Way is to allow a Cock to every ten of them; and this

this Way they will breed to the fulleſt Advantage.

CHAP. XXIX.

Of the breeding of Poultry.

THE Yard being thus ſtock'd with theſe Poultry in proper Number, of the fitteſt Kinds, and with the choiceſt of the Breed, the Farmer is to conſult the managing them to the beſt Advantage for their Breeding.

The Age is a conſiderable Article in this Reſpect; and he is to be very careful in ſuiting their Employment to that: for it would be very ill Huſbandry to ſtop the profitable laying of a young Hen, by ſetting her upon her firſt Eggs, when there are ſuch as are fit for nothing elſe, and will do this better.

As the youngeſt Hens are always the beſt Layers, and thoſe advanced into Years are the beſt Sitters, let theſe be managed ſeverally accordingly. And in both theſe Reſpects the Farmer is to have Regard to the feeding: for any Extream is equally wrong, whether in Exceſs, or in Defect. If they be ſtarved or kept too low, they will want Strength and Spirits; and if they be fed too high they will grow fat. A fat Hen is always lazy, and will never lay well, nor ſit quietly. The feeding them moderately while laying, or while ſitting, is the right Method.

The beſt Seaſon of the Year for Hens ſitting, is Spring and Summer; the earlier in Summer the better, and the firſt Months of Spring beſt of all. MARCH is the beſt Month for Chickens to be hatch'd, and the Middle of that Month is the moſt favourable Time of the whole Year. The Hen ſits only twenty Days, ſo from this Account it will be eaſy for the Huſbandman to know when to put her upon the Eggs for the beſt Brood; that is, in the laſt Week in FEBRUARY; and from that Time he may continue breeding till the firſt Week in OCTOBER.

The prudent Huſbandman ſhould never ſet a Hen that is leſs than two Years and a half old; from this Time to five, or between five and ſix Years is the beſt Time of that Creature's Life for ſitting, and producing Chickens. The fineſt Broods will be obtained when theſe two Conſiderations are regarded together; that is, when a Hen of a good Breed, and of about three Years old, is ſet in the Middle or End of FEBRUARY, upon a Parcel of well choſen Eggs laid by a young Hen of a good Kind alſo, who has let no Cock come near her but her own, that the Breed may be kept entire.

We have obſerv'd, that in order to the having a due Quantity of Eggs, the Hen that lays muſt be kept moderately: ſhe muſt be fed ſo as to have Health and Vigour, and not to grow fat: but there is ſomething to be ſaid for the Kind of Food, as well as the Quantity.

The Pretences of increaſing the laying of Hens by particular Diet, have been ſlighted by ſome; but they have been ſince confirmed upon the repeated Trials of others, and no Argument can ſtand againſt Experience. Many Kinds of Food have been preſcribed for this Purpoſe, but there are two moſt authorized by Experiment, theſe are Buckwheat and Hempſeed: the Effect of theſe is equal in Reſpect of laying; but the one fattens at the ſame Time the other does not, therefor the Condition of the Hen is to fix which is preferable.

If ſhe be inclined to fat, then Buckwheat muſt not be given, becauſe while it tends to make her lay by its common Virtue, it will alſo increaſe her fat ſo as to take her off: in this Caſe Hempſeed is the proper Kind. On the other hand, when a Hen is poor, the proper Kind is Buckwheat, for at the ſame Time that it inclines her to lay, it gets her into Fleſh.

As to the Number of Eggs to be put under a Hen for ſetting, there have been different Opinions; but by what I have found from many Trials, the beſt Number is ſeventeen. Let Care be taken that they be freſh and ſound Eggs, and let the upper Side of every one of them be mark'd blue; when the Hen gets from her Neſt for feeding, or waſhing herſelf, let the whole Number be carefully examin'd to ſee if ſhe have turn'd them all, or any of them. Such as ſhe has not turn'd, the Owner muſt ſee turn'd for her. And from this he will know how to value her for ſetting afterwards; for the Hen that turns all her Eggs herſelf, is greatly preferable to thoſe negligent ones which omit that needful Caution.

Every good Houſewife knows how to judge of the Newneſs and Soundneſs of her Eggs by holding them up to the Light, and ſeeing that they be full and clear. This is never ſo neceſſary as in the Choice of thoſe Eggs which are to be ſet for hatching.

When a Hen is ſet, ſhe muſt never be diſturbed againſt her Will; and ſome Care muſt be taken to ſet her Food and Water. If ſhe be put from the Neſt againſt her Will, ſhe often forſakes it entirely; and if ſhe be obliged to go to ſeek for Food and Drink, oftentimes ſhe is obliged to be abſent ſo long in the Search, that the Eggs chill, and the Chickens are killed in them.

This Care is needful during the whole Time of her ſetting, but is moſt of all to be ſtrictly obſerved toward the End of the Period. The Chickens are then formed in the Eggs, and they require the conſtant Warmth of the Creature's Body to keep them alive, a ſmall Time of chilling will utterly deſtroy them.

When the Hen riſes from her Eggs, eſpecially at theſe Times, to feed upon what is ſet before her, the Perſon who has the Care of her, ſhould ſtir up the Straw of her Neſt, and lay the Eggs regularly together, that ſhe may find all convenient and agreeable at her Return.

The Cock is alſo to be watched upon theſe Occaſions, for when the Hen is off her Neſt, he will offer his Service to ſet for her, but he does this very awkwardly, he frequently breaks ſome of the Eggs; and the Hen is always diſpleaſed at it. Sometimes ſhe will entirely forſake the Neſt upon it.

In the Choice of Eggs for ſetting, if there be any larger than uſual, they are to be rejected, for

for they will not lie even, and will cool thoſe that are next them. Theſe often have a double Yolk, and they are the Eggs which commonly produce thoſe monſtrous or misſhapen Chickens, which ſurprize the common People, among the Broods of this Creature.

As nothing more is requir'd for the hatching of Chickens than a due Degree of Heat, there has been long a Cuſtom in Ægypt, of hatching them without the Help of Hens, in Ovens, by Means of a ſmall and regular Fire. They in this Manner produce vaſt Broods at a Time. This Cuſtom has of late been attempted to be brought into Europe; in France the celebrated Monſieur de Reaumur has made many Experiments, and at length with ſome Succeſs. From the publick Account he gave of this, the ſame has been attempted in England, and among other ingenious Perſons, the Honourable Mr. Stanhope try'd it, and ſucceeded: but there does not ſeem any Probability of its being brought into common Uſe; and indeed ſo much Nicety is required in the Thing itſelf, and ſuch a great deal of Care of the Chickens after they are hatch'd, that it appears rather fit for an Amuſement for the Curious, than an Employment for the Huſbandman. We have ſeen that it may be done; and that is all that 'tis worth our while to regard about it.

If it happen that a Hen dies, or a Brood become by any Accident Motherleſs, the beſt Method is to mix them among the Chickens of another Hen that are about the ſame Age, and ſhe will take Care of all together. A Hen may thus be brought to conduct and aſſiſt three or four Broods: and this is the moſt favourable Circumſtance concerning the hatching of Eggs by Art; but there is a Limitation in the Number; and at preſent the Attempt is not to be recommended to any on the Foundation of Utility or Profit.

Although we have fixed the ſetting of the Hen to the Summer and Spring Months, it is not to be underſtood that they will not ſet at other Times. Eggs may be put under them at any Seaſon of the Year, and they will hatch them; and for thoſe that chuſe to beſtow a ſufficient Time and Attendance upon them, the Winter Broods may be worth raiſing, for they bear the beſt Price when they are grown up for Sale in Spring. This, however, requires more Trouble than the Huſbandman can well beſtow upon ſo ſmall an Article in his Stock; and therefore it is we have recommended the ſetting of the Hens in the End of February to any other Time; for a Brood of March Chickens will be worth near twice as much to him in this general Way, as thoſe of any other Time.

When the Breed of Chickens is the only Care, the white Fowls with white Legs and white Beaks are to be prefer'd to all others, becauſe of the Whiteneſs and natural Tenderneſs of their Fleſh, and their Price on that Account in the Markets: but theſe are not the beſt Layers.

Therefore if Eggs be the principal Care, the red Cock and mottled Hen are to be prefer'd.

If a Hen that has been fed with Buck-wheat to make her lay frequently, grow too fat upon that Diet, ſhe muſt be fed with Oats: for they at the ſame Time that they take down her Fat, aſſiſt her breeding of Eggs.

In all theſe Articles of feeding, it is not intended that the Fowl ſhould be kept upon thoſe Things entirely. She ſhould be left to take ſome Care of herſelf abroad, for her ſtirring about will do her Service; only what Addition to her natural Food is requir'd to keep her in Health and Strength for laying, ſhould be of theſe Kinds.

CHAP. XXX.

Of the bringing up of Chickens.

WE have led the Huſbandman, or rather the good Houſewife, (for this Care naturally falls upon her) from the Purchaſe of the Stock in this Kind, to the hatching of the young Brood: theſe are the moſt eſſential as well as the moſt valuable Articles that falls under this Head, and we ſhall therefore lay down ſuch Rules for the breeding them up to the Condition for Market, as Experience has ſhewn are the moſt uſeful.

We have mention'd twenty Days for the Time the Hen ſets: this is the earlieſt Period at which an Egg hatches, and as ſome are longer than others according to the Thickneſs of the Shell, their Place under the Hen, or other Accidents, they ſometimes are one and twenty, and ſometimes two and twenty Days.

In this, Patience is the Remedy. There have been ſeveral Ways propoſed of aſſiſting the Hen in hatching, and the like, but they are fooliſh and unneceſſary. All is to be left to Nature.

In large Broods eſpecially, it often happens that ſome Chickens are thus hatched a conſiderable Time before the others, often one, and ſometimes two Days. In this Caſe let the Hen be watch'd to ſee how ſhe treats them, for if ſhe be careful, nothing better can be done than to leave them with her. But if ſhe be reſtleſs, and ſeem troubled with them, it will be beſt to take them away.

In this Caſe let a little Wool be put into the Bottom of a Sieve, and let them be ſet in the Reach of the Warmth of the Fire, if the Air be chill; and thus nurſed up till the Hen has hatched the reſt, and can take them under her Care. During this Time nothing is needful but to keep them warm, for the Chicken in the two firſt Days requires no Food.

For the firſt feeding of the Chickens, the beſt Thing in the World is a Mixture of white Bread Crumbs and ſmall Oatmeal. Let a Quantity of theſe be mix'd well together, and then put a part of it to ſteep in Milk, and keep the reſt dry. Give the Chickens a little of each Sort at Times, as they follow the Hen.

After they have thus got a little Strength, they are to be fed with Bread ſteep'd in Milk, and then with Barley-meal and Cheeſe-parings cut ſmall, and the like, and the Hen will by this Time greatly aſſiſt in the providing for them, tho' at the firſt ſhe can do little more for them, than the keeping them together, and nouriſhing them by her Warmth.

In cool Weather it is always beſt to keep young Chickens within Doors, till they have got ſome Strength. At the worſt Seaſons, during the Months we have recommended for breeding theſe Creatures, they need not be kept within Doors above ten or twelve Days, after which they may be ſuffer'd to go about Abroad with the Hen, and in the better Seaſons, the leſs of this keeping them within will be neceſſary; often ſcarce at all.

It is a very material Thing to let the Chickens, while they are young, have good Water, for they fall into half the Diſeaſes to which they are ſubject, from the being obliged to drink ſuch as is foul, or any thing they can get at.

By Means of the Food we have directed for young Chickens; and the giving them Bread, ſcalded with Milk, and ſome Barley Meal afterwards, they may be fatten'd up while they are under the Hen. This is a very common Practice in IRELAND, and according to the common Error of Expreſſion in that Country, they call theſe ſucking Chickens.

The moſt general and uſeful Time of fattening them is, at a ſomewhat more advanced Growth. To this End when the Hen forſakes them, which ſhe always does as ſoon as they are fairly able to provide for themſelves, they ſhould be taken up and put into Coops, in a darkiſh Place, and there fed for fourteen or fifteen Days. Their Quietneſs aſſiſts greatly to the fattening of them; and they will always be moſt quiet where they have leaſt Light.

In theſe Places they are to be fed in the Manner that is called craming, and the beſt Food is ordinary Wheat Flour, made into a Paſte with Milk. This is to be ſoak'd in Milk, and then broke into ſmall Pieces, which are to be put down their Throats, always wetting them well in Milk firſt, that they may go down eaſily.

Some prefer Barley Meal to Wheat for this Purpoſe; and others ſpeak greatly of the Meal of Buck-wheat: but from many Tryals it appears, that Buck-wheat Meal does not anſwer well alone. A little of it mix'd with the Wheat Flour before it is made into Paſte, may do very well; but too much is not profitable.

There is one Article attending this Manner of fattening Chickens for the Market, which ought to recommend it greatly to the Huſbandman, that is, the Advantage of their Dung. The Price they bring at Sale will very well pay the Expence and Trouble of this Way of feeding them, and he has this Addition to the Profit. We have mentioned, in its Place, this Article of the Dung of Poultry, and here it has a great Advantage, as it is naturally collected together, and he may uſe it before it has loſt any Part of its Virtue, by being expoſed to the Air.

CHAP. XXXI.

Of Capons.

THE Capon which, when properly managed, is a delicate Bird, and brings a good Price, is the common Cock gelt, and fed properly.

The Time for gelding the young Cocks is as ſoon as the Hen has left the Chickens, or if the Pullets be not, at that Time, come ſoon, he is to be watch'd, and to be gelt as ſoon as he is heard to crow; for at this Time the Veſſels are always eaſy to be found.

The Art of Gelding, which by a peculiar Term is called Carving, has nothing particular or difficult in it. The Veſſels are to be cut out, and the Wound heals of itſelf without any Kind of Trouble.

The Hen being ſpay'd fattens in the ſame Manner, and with the ſame Management becomes a very fine Fowl.

The Capon being naturally inclined to fatten, will grow to a fine Size and delicate Flesh in the Yard, and at the Barn-Door, without any particular Care or Trouble: if ſome Meat be given him additionally to what he thus picks up, he will come into good Caſe the ſooner, and thus be very well fitted for the Table; but in order to make him bring the largeſt Price at Market, he is to be cram'd in the Manner of Chickens. This makes him grow, in a little Time, to a great Bulk; and makes his Fleſh very delicate.

In order to cram Capons, let them be taken up and kept in a ſmall, quiet, dark Place. Where they are to be fed in the Way of the Chickens, and their Dung is to be ſav'd in the ſame Manner, it being of equal Value.

The beſt Food is found to be Barley Meal, mix'd with Milk into a Kind of Paſte: this is to be of a moderate Stiffneſs; and is to be ſhap'd out into long Pellets, which they call Crams, largeſt at the Middle, and ſmaller at the Ends; theſe are to be wetted in warm new Milk, to make them go down eaſy; and he is to be fed with them three Times a Day: this is to be continued eighteen or twenty Days, and he will then be a fine Creature.

Regard ſhould be had to the Dung, not only for its own Value, but for knowing the Capon's Health. The general Rule is this, the finer the Meal be ſifted the ſooner it paſſes through him: ſo that by this Means only, of giving it finer or coarſer, he may be kept in a proper Condition during the whole Time of his craming.

If the Huſbandman live at a Diſtance from any large Town, or where there is not a Demand for Capons for the Table, it will not be worth his while to cram any; but ſtill he ought to breed ſome always among his Stock, becauſe they will come into a very good Condition for his own Table, by feeding in the Yard among his other Poultry; and they may alſo be put to a very conſiderable Uſe, in the bringing up Broods of Chickens, or any other Kind of Poultry. The Capon is to be tricked into this at firſt; but when he has once well taken to it, he will be vaſtly pleas'd with it; and will diſcharge his Duty like a Mother.

For this Purpoſe, the large Bulk, and ſoft Fleſh of this Fowl is an Article of great Advantage, for he is able to cover a larger Number of Chickens than an Hen can, and he will keep them warmer.

The thing that tempts the Capon to take this

Charge upon him, is the Pleaſure he has in feeling their ſoft and tender Bodies; and the good Houſewives having found this out, uſe a Method to make it more comfortable to him, by purpoſely putting him to pain, that he may want it.

To this Purpoſe they ſting the Breaſt and Belly of the Capon with Nettles, pulling away a Part of the Feathers for that Purpoſe: they do this toward his rooſting Time, and then in the Dark they put the young Brood under him; the Warmth of their Bodies allays the itching, and when he ſees them in the Morning he takes to them, and will lead them as naturally as a Hen.

The Care of the Capon, in this Inſtance, is not limitted to Chickens; for he will, in the ſame Manner lead young Turkeys, Peahens, Pheaſants, Ducks, or Partridges, and will be better to them than their natural Mother, fighting any of their Enemies, and ſheltering them under his Body on every Occaſion. If he grows negligent of them before they are fit to be left to themſelves, the Method is to ſting him again, and he will take to them as naturally as at firſt. Some ſcratch the Capon with Briars, or prick him with Furzes, to this Purpoſe, but theſe are more cruel Ways, and do not anſwer the Purpoſe like the ſtinging.

Before we cloſe this Head of Fowls it may be proper to give the good Houſewife one Caution about the collecting of her Eggs, eſpecially when ſhe has a large Stock of Poultry. The Eggs ſhould be taken out of the Neſt every Day, and the proper Time is the Afternoon, when every Hen has left them. The Neſt Egg is always to be left, but never any more; and in the Place of a Neſt Egg, ſome cut a Lump of Chalk into the Form, and it anſwers the Purpoſe.

Many Hens make ſuch a cackling as ſoon as they have laid, that the Houſewife may be aſſur'd by that, of her Time to go and take their Eggs, but they do not all do this: ſome make no Noiſe; ſo that the beſt Way is to have one Time of the Day to go the Rounds when every Hen is off, and collect all the Eggs together.

The Preſervation of Eggs for their keeping a long Time, is a thing that has employed the Thoughts of many, and a great Number of Methods have been propoſed, many of them idle enough, but ſome uſeful. They have been laid in Straw and in Bran, but the firſt keeps them too cold, and the latter too hot. The putting them up in Malt has been found preferable to either of theſe. But the beſt Method is by dipping them in Fat.

The Way that an Egg ſpoils is by the waſteing of its Moiſture through the Shell, and this is prevented by any thing that will ſtop up the Pores of the Shell. No Method is found to anſwer this End ſo well as the covering them with ſome fatty Subſtance; and the beſt Way of doing this is by melting a Quantity of Fat over the Fire, and dipping the Eggs in it. They will bring away ſo much as will cover the Shell ſufficiently for this uſeful Purpoſe.

We owe this Invention to the French, and it has been diſcover'd by their Philoſophers; for in that Country the greateſt Men are not aſhamed to meddle with the meaneſt Subjects that can be of publick Utility.

CHAP. XXXII.

Of Turkeys, their Kinds and Choice.

THE Turkey is a very large and fine Bird, and exceedingly well worth the Regard of the prudent Huſbandman. There are Advantages and Diſadvantages attending upon the raiſing of this, as other Kinds of Fowl; but all being weighed together, the former far outweigh the latter, and the Intereſt of the Farmer will lead him to think very ſeriouſly of receiving them as a Part of his Stock.

There is alſo this farther Encouragement to his Induſtry, that a great many of the Diſadvantages attending the keeping of this Fowl, may be remedied or prevented by prudent Management: and that there is no kind among all the Poultry which will afford ſo many Opportunities of Improvement. There are ſeveral Breeds of the Turkey, much more different than thoſe among the Cock and Hen Kinds; and the properly chuſing among theſe, will greatly add to the Profit and Eaſe of keeping them.

Among the Advantages of the Turkey may be reckon'd his Size, the Price he fetches at Market when in good Condition, and the Quantity of his Dung, which is as valuable as any other Kind whatſoever. He is fit for Sale alſo in the common Condition at a good Price; and his Feathers are not to be neglected, in counting up theſe Benefits.

Among the Diſadvantages of Turkeys are to be reckon'd their ſtraggling Diſpoſition, their being liable to many Accidents, the Difficulty of raiſing them, and the frequent Deſtruction of them by Vermin; as alſo the Quantity of Corn they devour. If fed altogether with this, they will eat more than they can ever be worth; but to this it may be anſwer'd, that the feeding them with Corn is not neceſſary, for they will in general provide very well for themſelves; and in the ſame Manner we ſhall ſhew that every other Objection made againſt them may be removed: and that it will be greatly to the Farmer's Advantage to raiſe them in moſt Places.

This Kind of Bird always ſucceeds beſt for the Owner in open Countries, becauſe theſe are not ſo much infeſted with Vermin: and they are ſubject to ramble and to be deſtroy'd more than any Kind, as obſerved already. This may be a very reaſonable Caution for the Huſbandman not to keep them in improper Places; but we have Counties enough in England that are not at all liable to that Objection. We have often told our Pupil in theſe Studies, that he is to ſuit his Stock to the Nature and Circumſtances of his Farm; and this is only one Inſtance of that general Neceſſity.

There are ſeveral ſmaller Differences among Turkeys, reſpecting Colour and other Accidents; and there are Diſtinctions of more Conſequence, as they depend upon real Differences in the Kind. Among the common Breed of Turkeys there are two Sorts diſtinguiſhed by their Colours, a whitiſh or grey, and a darker. Theſe differ in many Reſpects: but the principal is this, that the white Kind breed excellently, but they

are

are tender, and the others require leſs Care, but they do not raiſe ſo many young.

It is a Thing remarkable in all the Turkey Kind, that they take very little Care of their Brood: but theſe leaſt of all. If a common Turkey, of the white Kind, have a large Number, ſhe will never miſs half of them, ſo the reſt keep about her; but among the black Kinds, if a ſingle young one follow the Hen, ſhe never thinks of the reſt, if they be all loſt; and even this Straggler ſhe will drop with very little Regard or Notice.

The Farmer is therefore here directed in part in his Choice. If he intend to beſtow a great deal of Care upon his Turkey, the white Kind are to be prefer'd, for they breed the beſt; but if he cannot beſtow ſo much Time upon them, let him chuſe the black: all that is neceſſary about theſe is to ſee that they are not deſerted while they follow the Dam, for after this they will take Care of themſelves.

There are Turkeys much more different from theſe than they are from one another. Of theſe the wild Turkey of VIRGINIA is the moſt valuable: this is large and dark colour'd. There is alſo a ſmaller wild Kind, of a dark Colour, that is much hardier. Either of theſe may be raiſed by the Farmer; or he may mix the Breed by coupling one of our common Turkey Cocks with a Hen of one or other of theſe Kinds. The ENGLISH and VIRGINIAN Turkey make a very good Breed, as has been found long ſince by Experience. The young from this Mixture are hardy, and will ſoon take Care of themſelves; and they are larger, and every Way better than the common Breed: they will raiſe their young ones with Care in the Fields, and bring them in at an Age when they can ſhift for themſelves.

Whatever Breed of Turkeys the Farmer ſhall, according to the ſeveral Circumſtances of his Situation, prefer, let him take Care to chuſe for that Purpoſe ſuch as are good of the Kind; and particularly the Cock. He muſt be a tall, ſtout, luſty, and ſpirited Bird. The Turkey is naturally ſtately and majeſtical; and the Cock that is choſen for the Breed ought to be ſo particularly. For if he hang down his Head and look peaking, he never will be good for any Thing as a Father for the Brood. The Hen ſhould be large and vigorous; and it is a general and true Obſervation, that ſuch as are tameſt are the beſt for the Care of their young.

CHAP. XXXIII.

Of the breeding and raiſing of Turkeys.

THE firſt Article to be conſider'd in reſpect of the Breeding of Turkeys is the Age of the Cock and Hen. The Cock muſt be young, for the Brood is never good unleſs he be in the Vigour of his Life; the Hen may be older, for her Care in ſitting and leading them is all that is requir'd of her, and in the latter Article the Cock often aſſiſts her, when he is of a kindly Sort.

The Turkey Cock for Breeding, ſhould be about two Years old; and the beſt Time for the Hen is at about four Years: ſhe may be employ'd in breeding till ſhe is ſix; but when ſhe is too young, ſhe is moſt apt to neglect the Brood; and when the Cock is at all declin'd from his Strength, they are weakly.

Turkeys are not natural to our Kingdom, and there is therefore always a Wildneſs about them. The Female of this Kind does not lay familiarly and conveniently about Houſes as the common Hen, but rambles to a Diſtance, and makes her Neſt among Thickets: for this Reaſon her Brood is from the Beginning more liable to Accidents. The Farmer muſt therefore be watchful about the Time of her laying, and take Care to get her into the Hen-houſe, and compel her to lay there: for this is the firſt Precaution, and it is a very eſſential one about the Brood.

It is a Cuſtom with ſome, if there be Convenience of Thickets, or a little Wood near the Houſe, to let them take their own Way, and lay and ſit there; and in the hardier Breeds, with a little Care of the young when new hatch'd, this will do very well; but there is never any Harm in the other Method, whatever be the Breed; and there is a much greater Certainty of Succeſs.

The Turkey naturally begins to lay in the Month of MARCH, and will ſit in APRIL. The Eggs are very large, and are excellent in the way of Food, particularly they have a reſtorative Virtue.

The proper Number of Eggs to let the Hen ſit upon is eleven, ſome adviſe thirteen, but commonly there is leſs Succeſs in that avaritious Method, for they cannot be all well cover'd.

It may be obſerv'd, that in talking of the Quantity of Eggs to put under a Hen Fowl of any Kind for ſetting, we generally ſpeak in odd Numbers, as eleven or thirteen, not naming ten, twelve or fourteen. The good Houſewifes have been taught from Generation to Generation, to put always an odd Number; and tho' they know nothing of the Reaſon they practiſe it ſuperſtitiouſly: the Occaſion is, that an odd Number will lie better, and in a more compact Heap, when we come to ſuch Quantities as are uſually ſet, than an even. This is owing to the Shape of the Eggs, and is a Fact any one may ſee on Trial; and on this is founded that old Maxim.

The Turkey ſits about ſeven or eight and twenty Days. Some of the Eggs will ſometimes be hatch'd at five or ſix and twenty, and ſome will lie till thirty, but the middle Time is the moſt natural.

The hatching of the Brood is the Time when the great Care is requir'd in their Management. The Turkey being naturally a Bird of a warmer Climate, is chill in this; and particularly the tender young. They muſt be kept very carefully at firſt, eſpecially ſuch as happen to hatch before others of the ſame Brood: the beſt Way is to put them into a Baſket with Wool in it, and ſet them before the Fire, at ſuch a Diſtance as to be gently warm'd.

From this Time the Farmer is to depute ſome body to act as a Parent for them, for the Hen is not to be expected to do much: they will follow her, and ſhould be permitted to do ſo in

the warm Part of the Day, and ſhe ſhould be manag'd to take Care of them. The Cock alſo will often watch over them, keep them together, and defend them better than the Hen; but neither are to be truſted without careful looking after.

The proper Method of managing them is this. They are to be kept in a warm and cloſe Place altogether while they are very young; and when they have got ſome Strength, they are to be let out two Hours after the Sun is up in the Morning, and taken in again before he ſets in the Evening: and in the mean Time they ſhould only be let into ſome walled Place, or ſome Incloſure ſo ſecure that they cannot ſtray.

At firſt they are to be fed in the Houſe, and afterwards in this open Place: and at all Times they muſt be allowed a ſufficient Supply of Food, for their Parents take at beſt but little Care to help them to any. The very beſt Food for them is green freſh Cheeſe, and while they are young, their Drink ſhould be only new Milk; afterwards Milk and Water, making it weaker and weaker till they come to Water alone, which they will then drink wherever they can find it. Curds are a very good Food for them, but not ſo well as Cheeſe. A very wholeſome Food alſo is a Kind of thick haſty Pudding made of Oatmeal, Water, and a little new Milk among it.

As the Tenderneſs of the young is one great Article in the Diſadvantage of the Turkey, indeed the greateſt, Care muſt be taken that the Hen do not ſet herſelf at too early a Seaſon. If the young are hatch'd in cold Weather, it is ſcarce poſſible to rear them without conſiderable Loſs; but if they be produc'd toward the latter End of May, which indeed is the moſt natural Time, as well as the beſt, they will have a much better Chance.

It is only while young that this Bird is ſo exceedingly tender; for, when grown up, it will bear the coldeſt of our Weather very well. Grown Turkies will ſtand our ſevereſt Winter Nights expoſed, better than our common Fowl. They are frequently ſubject to be loſt while young, by ſtraggling from the Dam, and one another, in which Caſe they become an eaſy Prey to any Kind of Vermin; but it is only while they are young that they are liable to this; for, when grown up, they are not only ſtrong enough to defend themſelves; but they always love to keep in Flocks together.

The Huſbandman who keeps many Turkeys, muſt take a great deal of Care to keep them out of his Garden; for no Bird does ſo much Miſchief there: but their Profit is very well worth the Trouble they occaſion in this and other Articles.

When the young Turkeys have by the Means already directed, been raiſed to ſome Strength and Bigneſs, they may be left to themſelves. They had Reaſon to complain of the Expence of keeping theſe Fowls, who feed them conſtantly with Corn, from the Time of their firſt eating dry Meat to the fattening of them; for they are very great Devourers: but we find by Experience, there is no Occaſion to feed them at all, either with that or any Thing elſe, till they are to be got ready for Sale. They will at all other Times take ſufficient Care of themſelves, and keep in very good Caſe with what they find under Hedges, and in the Yard.

They are naturally in better Caſe in Winter than in Summer; for they are an indolent Bird, but the Cold gets them a Stomach: and this is the beſt Time for fattening them for the Market.

In order to do this they muſt be taken up and houſed; but it is beſt not to keep them up entirely, for they will in that Caſe loſe their Food, and come on poorly. They muſt therefore be let out the greateſt Part of the Day, but it is beſt to keep them where they cannot run much about at theſe Times. The Food to begin fattening them with is good Barley, boiled till it is ſoft: Oats will do; but the Barley is found better. Let them have Plenty of this for a Fortnight, with ſome Air and Sunſhine, but a great deal of Reſt. After this they are to be cram'd every Morning as Capons are, with a Paſte made of Barley-meal and new Milk; this is to be made into long Pellets, and wetted in warm Milk to make it go down. They are to be well fed with this in the Morning, and then ſuffer'd to go out, but they are to be kept as quiet as may be. They are not to be cram'd any more each Day, beſide this Morning feeding, but during their being out, Corn is to be thrown to them at Times: this will keep them eating, and keep them quiet, for having Food thus before them, they need not ramble about to ſeek it; and thus they will in a little Time fatten up in a very fine, and even a ſurprizing Manner.

This is their proper Management from the Egg to the preparing them for the Market; in which it is plain, that all the Diſadvantages ſuppoſed to attend them, may very eaſily be obviated and prevented; and that all the Care that is needful about them is, when they are very young, and when they are preparing for the Market: at the firſt of theſe Times the leaſt Cold kills them; and at the other, they will not fatten well unleſs carefully tended: all the reſt of their Lives they provide for themſelves; and the Price they bring, whether ſold as Poults, or when grown up and fatted, is ſo conſiderable, that it very well anſwers all the Trouble.

CHAP. XXXIV.

Of Geeſe; their Kinds, and the Profits of keeping them.

THE Gooſe is a Fowl different in its Nature and Qualities from the Hen and Turkey, they living on Land only, and this, though in a great Meaſure on Land, yet a Part of its Time in the Water; for which it is qualified by the Nature and Make of its Feet contriv'd for Swimming.

The Huſbandman will therefore find it needful to conſider, in order to his determining concerning this Article in his Stock, how he is ſituated with Reſpect to Water. Of the ſeveral Water Fowl that are bred tame, the Gooſe is

leaſt

leaſt devoted to that Element, as it walks the beſt of any of them on Land, and finds the greateſt Part of its Food there. We ſee alſo that Geeſe will live where there is but little Water: but let not this miſlead the Farmer into an Opinion, that this Element is little needful to that Fowl, for tho' they will live where there is but little, they always thrive better where there is more.

The Huſbandman is to conſider, when he is about to raiſe his Stock, what Kinds ſuit him beſt according to the Nature of his Situation; and from this he is to be led in his Choice which to have in the greateſt Number. I would adviſe the Farmer, where he has but little Water, to breed ſome Geeſe; but where he has much of it, only to fall greatly into that Way.

Some may fancy it leſs worth while in any Caſe to be very careful about theſe Fowls, becauſe their Profit is leſs than that of the Hen or Turkey; but the Trouble requir'd about them is alſo leſs: and their Value is not ſo ſmall as ſome affect to make it. They are ſold at a good Price in Spring when they are young, and in Autumn when full grown; and beſide this, there may be a very great Profit made of their Feathers: many Millions of Geeſe are raiſed in ſome Parts of this Kingdom for no other Uſe whatſoever; and the Profit is found ſufficiently conſiderable.

I would therefore adviſe the Farmer who ſhall be conveniently ſituated for the breeding of Geeſe in Quantities, to look upon them as an Article of ſome Conſequence in his Stock; and I would have no one who has any Quantity of Water at all for them, utterly neglect them.

There are three or four diſtinct Breeds of Geeſe in different Parts of the Kingdom, though they are not ſo much regarded as the ſame Kind of Differences among other Fowls. We have alſo ſome others of Curioſity, but they are not worth the induſtrious Huſbandman's Conſideration.

The large grey Gooſe that is bred in the Fen Countries is preferable to any other Kind, both for Fleſh and Feather, and it grows to the biggeſt Size of any. We have beſide this a ſmaller grey Gooſe, and a ſmall dark colour'd. Neither of theſe are nearly ſo advantageous as the grey; and among the large Kind that are ſo called, thoſe are much better which are all of a Colour, than ſuch as are pyed or mottled.

This is to be obſerved, that ſome of theſe Breeds are more under a Neceſſity of Water than the others. The ſmall bodied dark colour'd Gooſe, of which Kind there are ſome almoſt black, will do where there is ever ſo little, but they are the leaſt profitable Kind of any. The large grey Gooſe requires moſt to have Plenty of Water, nor does it any where ſucceed ſo well as where there are running Streams: the leſſer grey, which is often pyed, will do with leſs than this, though it will not thrive unleſs there be ſome Plenty.

In the Application of theſe Diſtinctions to Uſe, the Farmer muſt obſerve, that if he will have many Geeſe where there is not Abundance of Water, he ſhould chuſe the ſmall grey Kind; but when he has Water enough, let him always take Care to breed the firſt mention'd Sort, which is much the beſt.

Beſide Water, a great Advantage for the breeding of Geeſe, is a good Quantity of Common: they will on theſe Places provide for themſelves in a Manner, without the Regard or Trouble of the Owner; and it is on the common Fen Lands in LINCOLNSHIRE, and the adjacent Counties, that they keep thoſe vaſt Flocks or Droves, as they phraſe it, of them, for the Sake of their Feathers. They pull theſe in ſome Places once, in others twice a Year, and find a ready Market for their Produce. They call this ſheering of their Geeſe.

Nothing agrees ſo well with the Nature of the Gooſe as Plenty of Room, or a damp Common. They will always breed of themſelves once a Year, and in ſome Places twice, bringing up the Broods with leſs Trouble or Loſs than any other Fowl whatever.

The general and natural Time of the Gooſe's breeding is in Spring, and the earlier the better for the Owner. For this Reaſon the Farmer who keeps them about his Houſe, will do well to beſtow ſome Care and Attention upon this Head, although they would raiſe their Broods if he did not.

Some Geeſe will not lay above nine or ten Eggs, ſome will go as far as ſeventeen: they rarely exceed that Number; and if ever they do, the beſt Method is to take ſome away before they ſit. A Gooſe will very well cover fifteen, ſeventeen is the utmoſt ſhe can; and there commonly is better Huſbandry in ſetting her on fifteen; for when there are too many, they only cool one another.

There are two Reaſons why that Gooſe is beſt which lays earlieſt; the one is, that ſhe will ſit earlieſt, and the green Geeſe will be ready in the deareſt Seaſon; the other is, that ſhe has the beſt Chance for a ſecond Brood that Year. But there are Diſadvantages as well as Conveniencies in this, for the Eggs that are laid in a very cold Seaſon rarely turn out to ſo good Account as thoſe ſomewhat later.

There is an Opinion, that if the Gander treads the Gooſe on Land, the Eggs do not anſwer ſo well as when the Copulation is on the Water, and from this they attribute the frequent failing of very early Eggs, to the Waters being frozen over when the Gooſe was trod; but this is idle: the Misfortune is owing only to the Coldneſs of the Seaſon.

CHAP. XXXV.

Of the breeding and feeding of Geeſe.

WHEN the Gooſe is about laying, ſhe is ſeen to be carrying Straws about continually in her Mouth. This is for the making her Neſt; in which the Owner will do well to aſſiſt her, eſpecially in the early Broods. Let him find out for her a convenient Place warm and quiet, and let him there make her a Neſt of Straw and Nettle Roots, whoſe Smell ſhe likes; and it alſo does good to the young.

In this ſhe will lay, and when he obſerves ſhe continues upon the Neſt ſome conſiderable Time after ſhe has laid, it will ſtand as a Proof that ſhe is about to ſit.

The Gooſe ſhould be ſuffer'd to ſit upon her own Eggs, for ſhe will not do it well if ſhe perceives any Deceit in this, though they be of the ſame Kind.

The Geeſe ſucceed well enough that lay where none knows of it, yet they will be greatly aſſiſted, and the Brood from the ſame Number of Eggs, will always be larger, if the ſame Sort of Care be taken of them that is allowed to other Poultry at the Time of their ſetting.

For this Reaſon the careful Houſewife will ſee when her Gooſe riſes from thē Neſt, to ſet a Quantity of proper Food before her, that ſhe may find it without Trouble; and ſome large Veſſel of Water that ſhe may waſh herſelf. The beſt Food is Bran ſcalded, or Oats; when ſhe ſets near a Pond or River, ſhe ſhould not be hinder'd from bathing herſelf, for ſhe will not ſit kindly if ſhe be not allow'd to follow Nature; and this bathing of herſelf at large is much better for her than the waſhing in any Veſſel that can be ſet; though that is a very needful Expedient where other Water is not near.

While ſhe is off the Neſt, the Houſewife will do well to turn the Eggs, if ſhe have not done it of herſelf: and when ſome hatch before the others any conſiderable Time, as they ſometimes will a Day or two, ſhe ſhould keep them in Wool, in a warm Place, till the others are hatch'd, and then give them to her with their Fellows.

The Time of a Gooſe's ſitting is from ſix and twenty to thirty Days according to the Seaſon. They generally ſit a Day or two longer in colder than in warm Weather, and ſometimes the Difference amounts to three or four.

The beſt Way of breeding up the Goſlings from the Egg is this. Let them be kept within Doors ten Days; in which Time they are to be fed with Barley Meal in Milk, or with Ground Malt, or Curds, or Bran ſcalded with Milk. After this they ſhould be ſuffer'd to go out in the middle of the Day, and at about a Fortnight old, the Gooſe ſhould be ſuffer'd to intice them to the Water.

They are thus to be tended and fed occaſionally, till they have got Strength enough to defend themſelves againſt Vermin, and are able to provide for themſelves after the Example of their Parents. For ſeveral Days after their firſt going out, they ſhould be brought into the Houſe at Night, and ſhould have ſomebody to watch them, for they are poor defenceleſs Creatures, and a Prey to every Thing; but when they are ſo far grown up as to feed well, and walk ſtoutly, they may be left without Danger to ſhift for themſelves. With leſs Care than this Broods of Geeſe will often ſucceed very tolerably; but this is no great Matter, and it in a Manner enſures their Safety.

There are two different Periods at which the Gooſe is fatten'd for the Market: Firſt, when it is very young; and, ſecondly, when it is grown. It is diſtinguiſh'd at theſe Times by two different Names; at the one, it is called the green Gooſe; and at the other, a ſtubble Gooſe. For the preparing it in the moſt advantageous Manner for either of theſe, it is to be fatten'd by a proper Manner of feeding.

The right Age for taking up the Goſling in order to fatten it for a green Gooſe, is at five Weeks; ſome take it up at a Month, and others at ſix Weeks old for this Purpoſe, and either Way does very well; but, for a general Rule, the middle Time between thoſe two is beſt. The proper Food for them is ground Malt, or Oats boil'd, given in good Plenty three Times a Day with Milk, or Milk and Water for the Drink. If they be ſhut up in a quiet dark Place they thrive the faſter; and by this Means they may be brought into excellent Condition in a Fortnight or three Weeks.

For the fattening of the ſtubble Gooſe, the ſame Method and the ſame Food are to be uſed, and in a Fortnight or three Weeks keeping, it will be ready for the Market. The taking them up ſoon after the Harveſt Seaſon, is a very favourable Time for this, becauſe in running in the ſtubble Fields, they will have got into tolerable Fleſh of themſelves; and then being kept quiet, and in the dark, and well fed with the nouriſhing Drink of Milk and Water, they ſoon fatten up to Perfection. It is a very good Cuſtom to put a little Barley Meal into their Milk and Water, and to let this ſtand conſtantly before them, which will increaſe the Power of the Food in getting them into the due Fleſh.

The natural Food of the Gooſe is principally Graſs. They will live very well upon this in Commons and waſte Places, where there grows little or nothing elſe; and thus they are to be kept during the greateſt Part of their Time. The ſtubble Fields are a great Advantage to ſuch as are to be fattened: for that Food which they pick up there from the Scatterings of the Harveſt is richer and more nouriſhing, and tends more to the Nature of that with which they are to be fed when put up for that Purpoſe. The proper Gooſe for feeding up in this Manner, is one hatch'd the foregoing Spring, that has run among the Stubble for about three Weeks: this never fails of taking to feed kindly, and grows fat ſoon.

The Proportion of the Sexes in this Kind is properly one Male to five Females. To a Flock of forty Geeſe, which is a very good Number for that Purpoſe, there are to be eight Ganders: more will be ſuperfluous, and with a ſmaller Number they will not breed to their full Advantage.

If while a Gooſe is in fattening it nauſeates its Food, and does not thrive as it ſhould, let there be ſet before it a Diſh of ſmall and clean Gravel. It will peck up this at Times, and by that Means recover its Appetite.

CHAP. XXXVI.

Of Ducks.

THE Duck is another of thoſe Fowls which Nature has deſign'd partly for the Land, and partly for the Water, but it is more of the Water

Water Kind than the Goose. It not only has Feet form'd for Swimming, but the Legs are so placed that it walks very indifferently, wadling as it goes, and is naturally more in the Water than on Land.

The Husbandman who is sensible that the more he observes the Course and Design of Nature, the better he will succeed in all Things; will perceive from this that whether he shall keep Ducks, or in what Number he shall keep them, are Questions in which he must be determin'd altogether from the Circumstances of his Farm.

As the Duck will be content with Puddles, he will find that he may keep some of them wherever there is the least Water; that is to say, he may keep some Ducks every where, for he can keep no Creature without it: but where there is Plenty of Water, and roving Room upon it, 'tis there the Ducks thrive, and especially where it is a running Water.

The Farmer therefore who is situated near a River, is best qualified to breed Ducks to Advantage; and although they do not come up to the Hen, Turkey, or Goose in Value, they have yet enough to make it very well worth his while to breed them. He is not to count the absolute Price of any Thing alone, in order to understand his Profits upon it; but its Price compared with the Expence and Trouble attending it; and thus he will find the Duck of a very fair Value: for as much as its Price is less than that of the others, so much less is the Care or Expence needful about it: the Duck is indeed so hardy a Bird, that it may be left in a Manner to itself; and its young so early take to the Water, that they are out of the Way of Enemies.

The only Time in which the Duck requires any Care, is while she is setting, because then being kept from going in Search of her Food, she will need to have some set before her: but at this Time the coarsest and most ordinary Kinds will do; at other Seasons she will live very well upon the scatter'd Corn about the Yard, the Offal of the House and Kitchen, and what the Current of a running Water is continually bringing down to her. The Duck is a very general and coarse Feeder, scarce any Thing comes amiss to her; yet her Flesh is delicate: among her good Qualities may be reckon'd this, that she is less mischievous than any other Fowl; and she lays Abundance of Eggs which are as good as those of the Hen, and hatches very numerous Broods, which are fit for the Market in the same Manner as the Goose at two Ages, when young, and when grown up: and in either Case they are very easily fatten'd.

There are several Kinds of Ducks kept in ENGLAND, but the greater Part of them for Curiosity, so that the industrious Husbandman needs not give himself any Trouble about them: the two Kinds he is to regard are the common tame Duck, and the wild Duck kept tame, for this Breed will become so familiar from Custom of seeing People, and being among others, that they are as manageable as the other.

Of the tame Ducks there are several Breeds, which, though they differ but in slight Particulars, are yet worth the Farmer's Notice as distinct from one another, because of their different Qualities or Ways of living. In general the wild Breed require more Water, and the tame will do much better than they to be kept in the Yard almost entirely, as must be the Case at many Farmers. Among the tame there are these Differences, there is a narrow beak'd Breed, which is hardier than the common Kind, and will do with yet less Water; and there is a Breed that have the Beak more turning up at the End: these are found upon Experience to be the better Layers. They do not bring up their numerous Broods so well as some of the others, but when Eggs are the principal Consideration, they are to be prefer'd.

The common tame Duck does the best in Gardens and Orchards, for there is none of them that is so cunning in picking up the Worms, Snails, or other Insects, or that devours them in such Quantity.

It is a very great Quantity of Eggs that may be had in the Season from the Kind just mention'd; and she will in the End sit very well, tho' the others better. In general it is found more profitable to set a Hen upon the Duck Eggs, than any Kind of Duck whatever, because the old one leads them when hatch'd, too soon to the Water; where, if the Weather be chill, some will be lost. They follow the Hen a good while upon the Land, and so get hardy before they venture.

About thirteen Eggs is the proper Number to let a Duck sit upon. The Hen will cover as many of these as of her own, and will bring them up as well, so that every Way she is more profitable for that Purpose.

When the Ducklings are hatch'd, they require no Care if the Weather be tolerably good; but if they happen to be produced in a very rainy Season, it is right to take them under Cover a little, especially in the Nights; for, though the Duck naturally loves Water, it requires the Assistance of its Feathers, and till they are grown, is easily hurt by the Wet.

The fattening of Ducks at any Age is very easy, and whether it be the Duckling, or the grown Duck, the Method to be used is exactly the same. They are to be put into a quiet dark Place, and kept in a Pen where they are to have Plenty of Corn and Water; any Kind of Corn will do, and with this single Direction, they will fatten of themselves extreamly well in fifteen or twenty Days; and will bring a Price that very well repays their feeding.

CHAP. XXXVII.

Of the keeping of wild Water Fowl; and of Decoys.

THERE are several Water Fowl resembling the Duck Kind, which People of Curiosity keep in some Places; and for which there is so good a Price paid in the Market when they are by any Chance brought thither, that it may be worth the Husbandman's while, where Nature has assisted in suiting his Situation to such an Intent, to follow the Method that has been taken by those who had no farther

View

View, than to ſatisfy their Fancy or their own Palates in the keeping of them.

As theſe are naturally wild Fowls, they are expected to be kept wild, in a Manner, though under the Care of the Farmer; and they muſt be humour'd in this Way; they muſt have a Place of Security; and Opportunities of hiding; they muſt not be diſturbed by Peoples often going near them; and they muſt be fed as it were by Stealth.

The great Intent in all this is, to make themſelves fancy they are wild, though in Confinement. In this Manner Teal, Widgeons, and many other of thoſe Water Fowl which bear a Price in the Markets, and which few think could be bred to the Service of the Farmer, may, where he has the proper and needful Conveniences, be rais'd in a Kind of wild State, and in conſiderable Plenty.

The firſt Requiſite to this is, that there be about the Farm a Spring of Water, upon ſome level Ground, that wets a moderate Extent, and lies to ſome Depth in different Places: this anſwers excellently; and there muſt be either this, or a Part of the Arm of ſome River, or Rivulet, that the Farmer has wholly at his Diſpoſal, otherwiſe it is in vain to attempt any thing in the Matter.

Having one or other of theſe Places, let him fence it well round; plant Oziers in different Parts, and encourage the Growth of Sedge and all Sorts of Weeds in others. The great Advantage will be, to give the Fowl that are to be put into it, as many hiding Places as poſſible. The Top is to be cover'd with a Net. And when all is thus prepar'd the wild Fowl are to be put in; and being kept very quiet, they will breed and live comfortably. The Hens of the ſeveral Kinds will hide their Neſts from the Males, for they never fail to ſuck the Eggs when they can get at them: and thus conſiderable Broods will be rais'd.

Theſe will provide for themſelves in a great Meaſure: and the Food that is to be given them may be Corn of the leaſt valuable Kind: this ſhould be thrown down in two or three different Places at Night, when they are at rooſt, that they may find it in the Morning. This will accuſtom them to come to certain Places, and will give the Owner better Opportunities of knowing what is his Stock, and of taking them when he finds it convenient.

At the Times when there are young there ſhould be ſcalded Corn thrown in, which the old ones will lead the Brood to eat: there is no kind of Creature more careful of the young, than theſe Water Fowl, nor are any Birds whatſoever ſo well or ſo ſoon able to ſhift for themſelves.

This is the Contrivance for the breeding theſe Water Fowl in ſmall Numbers, and ſomewhat of kin to this is that Method practiſed in the Fen Countries, of taking them in Decoys; which yields the Owner a prodigious Advantage.

The Decoy is no other than ſuch a watery Place as we have deſcribed already well planted, of large Extent, and properly managed for the taking of ſuch wild Fowl as come into it. Nature generally has made the Place, and all that the Owner has to do is to keep every thing quiet about it. This has no Covering at Top, nor Fencing at the Sides; its Extent is ſufficient to keep its thickeſt Parts free from Annoyance, and all is to be open for the Fowls coming in. There are Nets planted in proper Parts of the Decoy, and a Number of Decoy-Ducks, as they are called, continually well fed in it. Theſe, though of the wild Breed, are in a Manner tame; they know the People and are not afraid of them; for they find they are well fed by them, and ſuffer no Hurt.

Theſe Decoy-Ducks go out at Times, and ſettling among whole Flocks of wild Ducks, they, after a little while, lead them to the Decoy, and ſwim before them into the Nets: they know they ſhall not be hurt. The People take the wild Ducks they have brought, for Market; and turn them looſe for farther Service.

CHAP. XXXVIII.

Of the Swan.

THE Swan is a leſs profitable Fowl than the meaneſt of thoſe before mentioned: and therefore, notwithſtanding the Majeſty of its Figure, and Beauty of its Appearance, is leſs worth the Farmer's Regard than any. It is kept indeed rather for Oſtentation than Uſe, and more properly belongs to the Owners of Waters than the Renters of Land. However, as it is a common Bird kept tame, and approaches to the Nature of the others, it might appear an Omiſſion not to have given ſome ſhort Account of it among the reſt of its Kin: the more, as we propoſe to inſtruct the Gentleman with the Farmer; and though our Purpoſe be to his Advantage, yet we need not deny a few Words on ſuch Things as are kept, in a Manner, ſolely for Delight. This, notwithſtanding thoſe ſeveral Diſhes that we hear of, as made from the Swan, is the principal Uſe for which that ſtately Bird is kept.

The Swan has been deſign'd by Nature, in a Manner, altogether for the Water, for it walks very awkwardly on Land: but on the Water it has great Strength, inſomuch that at Times when the Hen ſits, the Male who guards the Neſt with great Diligence, is often very furious; and at any time will defend himſelf againſt a middling Dog; and will often drown him.

Swans require a large Compaſs of Water, and do beſt upon Rivers: where there is this Opportunity the Owner will be in the right to breed them, for they are kept without Charge, and are a great Ornament to the Rivers. Neither are they ſo hurtful as thoſe imagine who have been told they deſtroy the Fiſh, for their natural Food is Graſs, and the freſh Water Weeds, that run at ſome little Depth under the Stream.

They require no more Attendance than they do feeding, but being once put on the Water will, in all Reſpects, take Care of themſelves.

Thoſe who are very tender of their Swans will give them a little Attendance while they ſit, and they

they will do the better for it, though this is not altogether neceſſary.

They muſt chuſe the Place for their Neſt themſelves, which is ſo large that it is very eaſily ſeen; and if the Owner would aſſiſt them, he is firſt to do it by planting Boughs about the Place, if not naturally ſhaded, in order to keep off the Heat of the Sun; and after this, when the ſhe ſets, he is to ſet ſome Oats in a Trough near the Neſt, that ſhe may not be induced to leave the Eggs too long in ſearch of Food.

The Swan lays from ſix or ſeven to twelve Eggs, rarely more; and her common Brood is four or five, though ſometimes more. If the Eggs hatch nearly together the Brood is the larger, if not, when there are four or five young ones hatch'd, ſhe ſets off with them; and takes no farther Notice of the Remainder. To prevent this Accident the young ones may be taken from her as they are hatch'd; and then ſhe will continue ſitting to the laſt. Theſe firſt hatch'd young may be preſerved in Wool, and all committed to her Care at laſt.

The Time of the Swan's ſetting is from ſix to ſeven Weeks, and often there will be ſome of the young hatch'd three Days before the others. Theſe, if taken from the Parent, may have ſome ſcalded Oats and Milk ſet before them the ſecond Day, and they will feed readily.

When the Brood are hatch'd they follow the Dam in the Water, and ſometimes get upon her Back; and ſhe is ſo excellent a Guardian and Provider for them, that ſhe very rarely loſes any of the Number.

Thoſe who are fond of uncommon Sorts of Food will fatten Cygnets, or young Swans, for the Table. When this is intended, the Cautions already laid down, for keeping the Swan upon her Eggs till they are all hatch'd, ſhould be carefully obſerved, that there may be a Supply, and at the ſame time a ſufficient Brood of young to grow up.

If the young Cygnet be taken out of the Water and dreſs'd, there is not ſo ill-taſted a Fowl in the World, for its Food being River Weeds, gives the Fleſh a very rank and diſagreeable Taſte; but when they are fatted for eating, they not only get a great deal more and tenderer Fleſh, but it is of a better Flavour. They are, in this Caſe, much like the fed green Gooſe, only much larger in Bulk, and coarſer in Appearance; and their Taſte a great deal ſtronger.

The Method of fattening them is this. They are to be taken from the Parent at five Weeks old, and put in Pens in a quiet darkened Place: they are here to be fed to their full Appetite with Oats, and to have Milk and Water for drink. They will fatten up in a Month, and be fit for the Table.

This is the Method of managing them for ſuch as think it worth their while to be at that Trouble, but they are not worth it for any; and as they do not bring a Price at Market, the Huſbandman has nothing to do with the Thoughts of them.

CHAP. XXXIX.

Of the Peacock.

THE Peacock is a Bird kept like the Swan, more for its Beauty than any Uſe; and conſequently it falls rather under the Conſideration of thoſe who raiſe Fowls for their Amuſement, than ſuch as are induſtrious on theſe Heads for their Advantage: there are thoſe who make this Fowl turn to ſome Account for the Table, but 'tis a Dainty, not a common marketable Proviſion; and nothing is, on this Occaſion, worth the Farmer's Regard, that he cannot regularly take to Sale.

The Peacock is therefore to be looked upon as a Bird of Fancy, not of Uſe, by the Farmer, and 'tis hardly worth his while to give it Leave to take up the Room of ſome Fowl that might anſwer his Purpoſe: for the Sake however of thoſe who ſhall chuſe to raiſe them for their Beauty, we ſhall lay down a few ſhort Obſervations on their Nature and Qualities.

The Peacock is at Land what the Swan is upon the Water, the ſtatelieſt and moſt beautiful of the feather'd Kind. It is very tender while young, but afterwards hardy enough; and as it requires little Care, and finds itſelf in Food, it may ſometimes be worth the Farmer's while who lives near a large Town, or where there may be a Demand for the Chick, by thoſe who keep them for their Beauty, to allow one Peacock and Peahen to run among his Poultry.

The Peacock is not only kept without Expence, but he is uſeful to the Owner in his feeding. He not only provides for himſelf, but rids the Ground of Vermine, in that Article, for his Food is Efts, Toads, and Snakes. He will eat Corn when he can get it, but this is his common Diet.

The Peahen will make her Neſt in Thickets and Buſhes; and ſhe takes all poſſible Care to hide it from the Cock, for he in this, as in many other Kinds, will deſtroy the Eggs if he can find them.

When the Peahen has ſet herſelf, it will be proper to put ſome Corn and ſome Water near her, that ſhe may not be under a Neceſſity of leaving her Eggs to chill, while ſhe is ſeeking at a Diſtance for Food.

The Time of her ſitting is thirty Days, and as the Chicks are very tender when firſt hatch'd, they muſt be houſed for ſome Days, the Cold ſoon killing them. During this Time they are to be fed with freſh Cheeſe, or with Barley Meal and Water. They muſt be let out in the Middle of the Day, and taken in again at Night, for ſeveral Days, and when they have, by this feeding and Management, got ſome Strength and Bigneſs, they are to be truſted out with the Dam, and then no farther Care need be taken of them. The Cock ſeems not to own them till the Feathers that form the Coronet upon their Heads begin to riſe; but after this he is as fond of them as the Hen, and will call them about him to feed, providing for and defending them with great Care.

From the Time of their going at large with the Hen, they need no more Care of feeding or

Attendance, except any one has a Mind to fatten them for the Table. If this be done, the uſual Time is when they have arrived at about half their Growth, and they are then put in a Pen, in a dark quiet Place, and fed with any Kind of Corn as much as they will eat, and have Plenty of freſh Water. Quiet, and Plenty of Food will thus make them fat in about a Month's Time, and their Fleſh will be better taſted than when they run at large, and take their natural and coarſe Meat; but at beſt they are inferior to almoſt any Kind of Fowl, and have a very ſtrange, raw, and bloody Appearance, when they have been ſet by for a Night after Dreſſing.

CHAP. XL.

Of the Pheaſant.

THE Pheaſant, though naturally a wild Bird of the Woods, is much of the common Poultry Kind, and may be bred in the ſame Manner in proper Places erected and contrived for that Purpoſe: but as this is an Article in the Way of the Gentleman rather than the Farmer, we ſhall not detain our induſtrious Reader with any long Diſcourſe on the Subject.

There are Pheaſantries in many Parts of England, where Numbers are annually bred, and grow up; but there requires a great deal of Care about them when young; and a Regard to their Danger from Kites, Hawks, and other Birds of Prey at all Times; for the Pheaſant is of all Fowls the delicate and favourite Bit with theſe Devourers.

The rooſting Places are to be well defended for this Reaſon, and the Fence is to be high to prevent their Eſcape. They lay freely, and bring out large Broods, but ſeveral die in ſpite of all poſſible Care in the raiſing; however, with good Diligence, a Number of them may be rear'd.

The natural Food of the young Pheaſant is that white Subſtance called the Ants Egg. The old ones in their wild State lead them to the Ant Hills in the Woods for this, and they muſt be ſupply'd with it in Abundance by the Induſtry of the Keeper, when bred tame, otherwiſe they droop and come to nothing; this occaſions a great deal of Trouble at firſt with them, but after that they will be train'd up with great Eaſe, for they will eat any Kind of Corn, and they are not tender or difficult to raiſe.

CHAP. XLI.

Of Pigeons.

WE come now to treat of a Fowl ſmaller in its Size than any of the before mention'd Kinds, but ſuperior to many of them in Value; the Pigeon. The Management of this Bird is alſo different in a great Meaſure from that of the others, ſo that it naturally falls under Conſideration ſingly. But there is no one of all thoſe Kinds about which ſo much Care is generally taken, that is more worthy of the Notice and Attention of the prudent Huſbandman.

It is a great Recommendation of any Creature to the Farmer, that it will be kept at ſmall Expence, and this is the Caſe with the Pigeon, which he ſhould keep; for there are ſome Kinds that require a great deal of Food and Charge: the proper Pigeon for the Dovecoat, which is the only Kind he is to regard, is able the greateſt Part of the Year to provide for itſelf; and when it requires his Aſſiſtance, the Food is not of any dear Kind. Beſide the common Advantages of the Breed, there is that great Article their Dung, which we have treated of in its Place; and which we have ſhewn to be of ſuch great Service as Manure, that it muſt be the Intereſt of every Farmer to provide it for his own Uſe, eſpecially as that is to be done with great Eaſe, and the ſame Method that affords it will yield him alſo a great many other Advantages.

There are at this Time many Kinds of Pigeons kept in England, by People fond of Curioſity, and it has become a Study to procure and raiſe new Kinds among thoſe who are called Pigeon-fanciers, as much as to get from Abroad, or raiſe from Seed, new Kinds of Carnations or Auricula's among the Floriſts. But with this the induſtrious Huſbandman has nothing to do. He is to keep Pigeons for their Value, not their Beauty; and he is to conſider which may be kept with moſt Eaſe, which is in his Way one of the greateſt of Recommendations to any Thing.

Not to enter into the nice Diſtinctions of the Kinds which are of late Years become endleſs and innumerable, we may ſay in general that there are two Sorts; the tame, and dovecoat Pigeon. The tame Pigeon is valued not only for his Beauty, but for the Largeneſs of its Body; the common Pigeon, which is the Kind uſually kept in Dovecoats, and thence called the dovecoat Pigeon, is ſmaller, and leſs beautiful.

The tame Kind generally have but two young ones at a Brood; but they make ſome Amends for the Smallneſs of the Number by the frequency of their hatching; for, if well fed and tended, they will have young ones every Month.

For the Choice of theſe the Beauty is generally moſt regarded; but there ſhould be Care taken to pair them well, and this is the more worth while becauſe they are not apt to ſeparate afterwards.

They muſt be kept clean, for they hate Dirt, though they make a great deal of it. But their Food is ſo dear, that few but thoſe who know very well how to manage them care to meddle with them. Their beſt Food is Tares or white Peaſe, and they ſhould have beſide this ſome Gravel ſcatter'd about, and clean Water at all Times: and a great deal of Care muſt be taken to preſerve them from Vermin, and their Eggs from the Starlings and other Birds, which always haunt the Places where they are kept, in order to ſuck them.

In order to the perfect Thriving of theſe Pigeons, it will be proper, beſide their Food, Gravel, and Water, always to let there be ſome Salt, Clay, or ſome other Thing with Sea Salt in it, for them to peck at their Pleaſure.

We have ſaid thus much with reſpect to the Management of the tame Pigeon, for the Information of ſuch as may chuſe to breed them, and have not had Opportunities of ſeeing it done; and it will

will be proper to add here, that although the Expence and Trouble they occaſion, be more than is worth the Huſbandman's while in general to give himſelf; yet there is this Advantage, that their Dung is richer than that of the common Pigeon as a Manure: this is owing to their Food, as has been explain'd at large in its proper Place.

After this ſhort Account of the tame, we come to the Conſideration and Management of the common or dovecoat Pigeon, which is a Subject that demands, and deſerves the Huſbandman's utmoſt Regard.

The keeping of Pigeons is a great Advantage to every Farmer that may do it; and they bring in a great Profit for a very ſmall Expence in all Places; but they thrive beſt in open Countries, becauſe there is uſually moſt Corn there, and they feed with leſs Danger, the Hedges in encloſed Places ſheltering People while they ſhoot them.

There are ſome Counties where the Huſbandmen ſow great Quantities of Horſe Beans and grey Peaſe, and in theſe particularly the Pigeons feed to a great Advantage. Theſe Sorts of Pulſe are ſow'd earlier than other Kinds of Grain; and their early feeding upon them makes them healthful and ſtout at thoſe Times, and is an Occaſion of their breeding earlier than they do elſewhere, which is a Conſideration of great Importance.

The common blue Pigeon is properly the dovecoat Breed; and it has the Advantage of many other Kinds in that it is hardier, and will live in the worſt Winters.

If it be too ſmall for the Farmer's Purpoſe, he may mend the Breed by putting in a few tame Pigeons of the moſt common Kind, and the leaſt conſpicuous in their Colours, that the reſt may the better take to them by finding them more like themſelves; this, however, is to be done with Caution, and never without a due Conſideration; for though the Bigneſs of a Pigeon's Body is a plain Advantage, yet it is very well known in the Kinds in general, that the ſmalleſt body'd are the beſt Breeders.

The Ringdove has been by ſome introduced into the Dovecoat, by ſetting the Eggs under a common Pigeon; they will in this Caſe live, and take their Chance among the Pigeons; and they have two Advantages over them, the one in their Largeneſs, and the other in their Hardyneſs; for they will endure any Weather, and live upon any Food.

The Huſbandman ſhould have a very careful Eye upon the Proportion of the Sexes among his Pigeons; for there is nothing ſo hurtful as the having too many Cocks, eſpecially if they keep the larger or tame Kind. It is his Buſineſs to keep his Dovecoat well ſtock'd; and moſt People who keep them make their Conſciences eaſy about deluding away thoſe belonging to their Neighbours; but this Abundance of Cocks thins the Dovecoat, for they grow quarrelſome, and will beat others away; till by Degrees a very thriving Dovecoat ſhall be by this ſingle Miſtake reduced to a poor Condition.

A very cheap and eaſy Way of making a Dovecoat is to build the Walls with Clay mix'd with Straw, they may be made four Foot or more in Thickneſs, and while they are wet it is eaſy to cut Holes in them with a Chiſſel or other Inſtrument.

This Kind of Dovecoat, beſide its Cheapneſs, has the Advantage of great Warmth, and no Building agrees better with the Pigeons. A Dovecoat of this Kind of four Yards ſquare in the Clear, may be built for about Five Pounds.

The Holes ſhould be made about fourteen Inches deep, and a little dipping backward. The Reverend Mr. LAWRENCE who uſed this Method of building his Dovecoat, ſays, That the Pigeons proſper'd in it better than in any Brick or Stone Building he had ſeen.

Of whatever Materials the Coat be erected, it ſhould be white-waſh'd frequently on the Outſide. The Pigeon, as has been ſaid already, is a cleanly Bird: it loves the Appearance of Neatneſs; and beſide the white Colour renders the Building more conſpicuous.

As to the Food of Pigeons, beſide the Peaſe and Tares already mention'd, Barley is very proper, heartening them very much, and making them lay; and for the ſame Purpoſe Buckwheat alſo is an excellent as well as cheap Food.

For the greateſt Part of the Year however, the common Pigeons in a Dovecoat take Care of themſelves, and need no Food from their Keeper. There are only two Seaſons at which it is neceſſary or proper to feed them. One of theſe Times is the Depth of Winter, when the Ground is cover'd with Snow, or harden'd ſo by Froſt, that nothing is to be got; and the other is, the middle or latter End of JUNE.

The Reaſon of feeding them in the firſt of theſe Seaſons is obvious; the latter, the Farmers when they ſpeak of this Fowl call benting Time. There is a Graſs called bent Graſs, the Seed of which is ripe about this Seaſon, and is the only Food of that Kind the Pigeons can eaſily get, the Peaſe being not yet ripe. This is a very poor Food, and the Pigeons at this Seaſon uſually have many young Broods; ſo that they will be ſtarv'd if they are left to this poor Diet; and the Farmer will always find his Account in giving them Food at this Seaſon, as well as at the other. This laſts however but a ſmall Time; and the other is only neceſſary at the ſevereſt Days of Winter; ſo that the Pigeon is at the utmoſt but a ſmall Expence, and that for a very ſhort Time.

Beſide the Food, the Breeder of tame Pigeons has been adviſed to give them a Lump of ſalted Clay, and the ſame Indulgence muſt be ſhewn to theſe. But as they are more numerous, there is to be a larger Allowance. A large Heap of Clay ſhould be laid near the Dovecoat, and the Brine of the Family continually beaten in among it. Another Way is to make a Kind of Mortar with Lime, Sand, Clay and Salt, which they will peck with great Satisfaction. The Pigeons themſelves have pointed out this Method, for they are continually pecking at the Joints of Walls to get out the Mortar. When it is thus made on Purpoſe for them, it is beſt to make it thin, and keep it ſo by often beating it up with Brine.

In ſome Places they lay what is called a Salt

Cat, near the Dovecoat. This is a large Lump of Salt made for the Purpoſe at the Salt Pans; and is the Method commonly taken where there are Works in the Neighbourhood, but the Way of uſing Salt in a Mixture with Clay is better.

What I have found by Experience to anſwer beſt of all is this. A Heap of Loam is to be laid near the Dovecoat, and beat up to a Kind of Pap with Brine or Water; into this is to be thrown a large Quantity of Bay Salt, and a little Saltpetre, and with it a Shovel full or two of large coarſe Sand. When Brine is uſed to beat up the Loam, leſs Salt is to be uſed; and when Water, there muſt be the more of it in Proportion. And in the ſame Manner if the Loam contain a great deal of Sand, the leſs is to be added to it; and if it contain leſs, the more is to be given. Where Loam is not to be had Clay will do, but then a much larger Quantity of Sand muſt be put in; and the beſt Sand for this Purpoſe is large coarſe Sea Sand, which is already impregnated with Salt Water; or that which is got in ſcreening of Gravel.

It is a very ſingular Thing that the Pigeon loves Salt in this Manner; and its Fondneſs for Saltpetre, which is very great, is not ſo well known; though this might have been diſcovered by obſerving the liking this Bird has to the Mortar in old Walls, which contains a Salt very nearly ally'd to the common Saltpetre.

Salt is not only uſeful in this Manner to pleaſe the Pigeons, when they are in Health, but nothing recovers them ſo readily from Sickneſs. A Mixture of Bay Salt and Cummin Seed being with them an univerſal Remedy.

A great many Contrivances have been publiſh'd; and many more are handed about among the Country People as great Secrets, for the making the Pigeons love their Habitation, and tempting ſuch Stragglers from their Neighbours as chance to come to the Coat to ſettle in it. Some have adviſed the Uſe of Aſſafœtida, and others of Cummin Seed before mention'd for this Purpoſe; but the beſt Method of all others is to keep up conſtantly ſuch a Heap of ſalted Loam as I have before deſcrib'd; this is what they love, and they will therefore ſtay where they can have it in Plenty. This Contrivance, with the Addition of keeping the Dovecoat neat and clean, and not ſuffering them to be diſturbed in it, will be ſure to keep the Stock in good Number, and too likely to increaſe it at the Expence of the Neighbours.

The Profit of Pigeons is very conſiderable, and very certain; for they breed faſt, and there is a conſtant Demand for them. Near great Towns it may be worth while to keep ſome of the large tame Kind; becauſe, although they cannot be fed but at a large Expence, yet their young come ſo early, and are ſo fat and fine, that they command a Price, which very well returns it: but in the Country the common Pigeon is the proper Kind; for though the Price that the Birds fetch is not nearly ſo great, their Number, and ſmall Expence of keeping, very well make Amends.

Among the Methods which are recommended for the drawing Pigeons to a deſerted Dovecoat, one of the moſt ridiculous is that of a baked Bitch. This is perform'd with great Ceremony: the Creature is to be killed at the Time ſhe is proud, or ſalt, and then ſtead, baked, and laid in the Dovecoat. Some improve upon the Practice, by putting Cummin Seed in the Belly: for the Pigeon is really fond of the odd Smell of this Seed, which is the moſt diſagreeable of all thoſe called Aromatick. This may therefore have ſome Effect; the other can have none; and yet the wonderful Powers of it have been recorded by many Authors. The plain Account of this is, that a Dovecoat has been deſerted becauſe of its Dirt and Naſtyneſs; and they have cleaned it out, and laid the baked Bitch in it. The Effect of the Cleaning they have laid to the Carcaſs of the Animal: for it is not the Countryman alone who miſtakes Cauſes.

I have ſpoke often to the Farmers to recommend their ſetting up of Dovecoats, but have found it in nothing ſo difficult to make them liſten to me. While they have bought Pigeons Dung at a great Price, and fetch'd it from a great Diſtance, they have ſtill been backward to think of keeping Pigeons themſelves for their own Supply. There is a Superſtition among them, that it is unlucky to ſet up a new Dovecoat; this has come down from Father to Son, and they perſuade themſelves it would certainly be follow'd by Death in the Family. Nothing can be ſo ridiculous, or ſo weak, as ſuch a Suppoſition; but there never was an old Woman's Tale ſo deeply rooted.

BOOK V. PART III.

Of FISH.

CHAP. XLII.

Of the Advantages of Fiſh Ponds.

FISH are not conſider'd ſo much as they ought, either by the Huſbandman himſelf, or by others, as a Part of his Stock; but we ſhall endeavour to ſhew from Experience, that it is as eaſy for him to manage theſe as any other of the already mention'd Creatures, and that the Profits ariſing from them are very well worth his Attention.

We are here treating of thoſe Animals which he may keep upon his Farm, or in his Grounds, and Fiſh are very plainly of that Number. He muſt have ſome Water, and he may, according to the Situation of his Farm, have a great deal.

Fiſh will live in this, and he may have a reaſonable Profit in all Caſes, and in many a very large one.

One Kind of Fiſh will live in one Sort of Water, and another Kind in another. There is ſome Species that will live in all; and he who has Water, and leaves it unoccupied by them, defrauds himſelf of a Part of his natural Advantages, as much as if he were to omit to put Stock into his Paſtures.

But there is a farther Conſideration yet in the Reach of the prudent and induſtrious Huſbandman. Whereſoever there is Water we ſee Fiſh will live: it is not only his Intereſt at all Times to put a Stock of them into Ponds, when he has them; but it may be very often worth his while to make them for this Purpoſe.

I have labour'd throughout this Work to put the Farmer in a Way of making the moſt Advantage from every Part of his Land; and have propoſed in the Plan of it to conſider in what Inſtances Art may, for his Service, come in to the Aſſiſtance of Nature; and in particular, how Pits may be converted into Fiſh Ponds.

I ſhall here enter into that Conſideration a little farther, and endeavour to ſhew, not only how he may ſtock whatever Water he has with Fiſh that is fit for that Purpoſe; and how render that in ſome Caſes proper for their Reception, which was before from ſome Circumſtance or Accident unfit for that Uſe; but in what Caſe it may be to his Advantage how to dig Ponds purpoſely for this Uſe.

There may be Parts of his Ground, which from their Nature and Situation will yield him little Advantage any Way elſe, and which may be converted to this Uſe with conſiderable Benefit. In this Caſe I ſhall adviſe him to put them to that Uſe, though at ſome Expence; and ſhall lay down the moſt advantageous Method of doing it. The Lands on which it may be proper and advantageous for the Huſbandman to make Fiſh Ponds, are of two Kinds; thoſe which are boggy, or naturally watery; and thoſe which although dry and firm, lie in the Bottoms between riſing Grounds. Theſe are to be ſelected for two different Reaſons; thoſe of the firſt Kind becauſe they are either fit for little elſe, or can no Way be made ſo uſeful; and thoſe of the ſecond, becauſe they will anſwer a double Purpoſe, the watering of Cattle, and the breeding of Fiſh. Theſe will be ſupplied by the Waters from the riſing Grounds, and will in this Uſe bring a great Profit, as well as great Convenience.

We are to remember in this Place, that we write to the Gentleman as well as to the Farmer: in that Light we may name the Supply of the Table from theſe Ponds as a very great Article; for all that is ſaved in Expence is got: and the Addition of good Fiſh in Plenty is a Conſideration of great Value to the Table of a Perſon of Fortune. The Farmer is only to conſider the Demand at Market; but this is abundantly enough to anſwer his Purpoſe. He will hardly deny himſelf the Produce of his Waters at his own Table; but 'tis not in that Caſe to be regarded as an Article of Profit, for Fiſh are not the Food for a Family.

When the Ground is fixed upon for the making a Fiſh Pond, let the Undertaker conſider, whether it have Springs to feed it, or muſt depend altogether on the Rains: for this makes a very different Management neceſſary. Ponds that have Springs will be ſafe from drying on an entire Flat: but there ſhould be a Deſcent to thoſe which are to ſupport themſelves by Rains, for without this they will fail at Times; and the drying up of a Fiſh Pond is a terrible Stroke upon the Owner.

When Flags and Ruſhes grow on a low Piece of Ground, 'tis a Proof there is Water near. We have ſhewn already of how little Value the natural Products of ſuch Lands are, and have laid down the Methods of improving them by Culture: let the Huſbandman conſider the Expence and Profits either Way, together with his own Occaſions for Water, and the Extent of the Ground; and then determine what Courſe to take to render it the moſt uſeful, and obtain from it the largeſt Profit.

On the other hand, in thoſe Grounds which lie between Hills, Ponds will have the Advantage of what is waſh'd from the riſing Grounds by the Rains. They will feed Fiſh, water Cattle; and alſo afford from their Bottoms a Manure of the greateſt Conſequence to the Farmer.

The Water that runs in wet Seaſons from the Hills, does not go off pure Rain: it waſhes away with it the lighteſt and richeſt Parts of the Soil, and alſo the fineſt Part of the Manures and Dreſſings the Huſbandman had laid on his Grounds. This enriches the Water, and feeds and ſupports the Fiſh in a ſurprizing Manner; and after all it is not loſt. The having Ponds in theſe Places is the true Way of ſaving it. All runs into them with the Water, and ſettles to their Bottom after a Time; and is finally left there. This is the Occaſion that Ponds ſituated ſo as to receive the Water from high Lands fill up ſo ſoon, but that is no Diſadvantage to the Owner; on the contrary, it is a laſting Source of Manure, and a great Benefit. Theſe Ponds are eaſily cleaned, and this Mud many Times over pays the Expence of the Work. In this Caſe it is proper that Proviſion ſhould be made for receiving the Fiſh during the cleaning of the Pond: the Perſon who thus foreſees the ſeveral Advantages of what he is about to undertake, will ſet about it with the more Spirit, and will contrive accordingly.

The Neceſſity of cleaning Ponds is abſolute, but ſo alſo is the Advantage attending it. The Time is very different according to their Situation. Ponds in an even Ground, that are fed by Springs, need not be ſcoured above once in fifteen Years; but thoſe which receive theſe rich Waters from Hills, ſometimes require it every four or five Years. And the others in Proportion, according as they partake more of the Nature of one of theſe or the other.

We have in ſeveral of the preceeding Articles of the Farmer's Stock, reminded him of the great Value of thoſe Creatures which are kept at a little Expence; this is no where to be more conſidered than here; for the firſt Expence is all. Many Creatures are to be kept at a little

Charge, as they in a great Meaſure provide for themſelves; but Fiſh entail no Expence upon their Owner at all, for they will do this entirely.

We ſhall hereafter obſerve, that it may be ſometimes worth while to throw into a Pond where Fiſh are feeding, ſome Things of very little Price, but even this is not neceſſary. The Fiſh of Prey are to be ſupplied by firſt ſtocking the Ponds with Roach, and the like Fiſh, which are of ſo little worth, that they are fit for nothing elſe; and are ſo numerous, that they may be often drawn up in a Net by Buſhels: for the reſt, Grains, or Refuſe of the like Kind, is all that can be given them.

Having ſhewn theſe Advantages of Fiſh Ponds properly ſituated, we ſhall in the next Chapter proceed to lay down the Methods of makeing them moſt advantageouſly, and with leaſt Expence.

CHAP. XLIII.

Of the making of Fiſh Ponds.

WHoſoever propoſes to make a conſiderable Advantage from Fiſh Ponds, muſt have ſeveral of them. He muſt have ſome to receive the Fiſh of thoſe which are cleaning; and he muſt have ſome for one Kind, and others for another. He who ſhould put his Fiſh of Prey and his others together, would find a very ſorry Account in the End.

There is a farther Conſideration alſo, which demands that there ſhould be a Number of Ponds; this is that they are intended for different Uſes. Some are for breeding, and others for feeding of the Fiſh. There ſhould be a diſtinct Pond for the Pearch, and another for the Carp and Tench; but he muſt have one Pond for his Carp to breed, and another for them to feed in; for Experience ſhews thoſe who never trouble themſelves about the Reaſons of Things, that in thoſe Ponds where Carp breed, they feed very poorly; and, on the contrary, in thoſe Ponds where they feed well, they ſcarce breed at all.

In general, Fiſh Ponds may be divided into two Kinds, ſuch as have ſharp and clear Water, and ſuch as have it ſoft and thick. The firſt of theſe are the Ponds for breeding, but the others are thoſe for feeding.

This may direct the Undertaker in general in his Work, and we ſhall in their Place add more Obſervations on this Head: from what has been ſaid of the Number and Variety of his Ponds, and their appropriated Uſes, he will the better conceive what is meant in every Particular of thoſe Directions we are about to give for the digging and conducting of them.

The beſt Method of all where the Ground and other Accidents concur to favour the Intention, is to have a String or Row of Ponds, where there is at the upper End a ſmall feeding Spring for the Supply of the whole, ſo that in dry Seaſons they may be ſure to be kept up with a due Quantity of Water; and there ſhould be alſo Contrivances for letting off the uſeleſs or abundant Water from them, that they may not be overflow'd.

At the Head of every Pond there ſhould be a Sluice, and this Head muſt be made in the loweſt Part of the Ground. A great deal depends upon the proper Structure of the Head, and Contrivance of the Sluice. The Head muſt be very firm and ſound, or it may give Way, and deſtroy the whole Work; and the Sluice ſhould be ſo made, that the Water may, upon Occaſion, be let off very freely and quickly: the great Care that ſhould be taken on this Head is, that there be a ſufficient Fall from the Sluice, for on this the Quickneſs of the Waters running off will depend, more than on any other Conſideration whatſoever.

In order to ſet about making the Head of the Pond, a proper Quantity of ſtrong Stakes are to be provided. They ſhould be of about ſix Foot long, ſtrait, thick, and of ſuch a Wood as will bear the Dampneſs of the Soil. For this, Directions have been given already in our fourth Book; where the Reader will find an Account of the ſeveral Natures of the Species of Timber, and the Purpoſes to which they are ſuited: ſo that he is to ſelect among the ſeveral Kinds that will anſwer this Purpoſe, that which he has moſt at his Command, or can ſupply himſelf withal moſt conveniently.

The Stakes being ready, let him ſet about his Work by driving them firmly into the Ground in three Rows, at four Foot Diſtance Row from Row, and about three Foot ſeverally in each Row. Theſe Rows muſt be carried the whole Length of the Pond Head; and the firſt Row muſt be driven four Foot into the Ground.

This is a very ſufficient Preparation for the Superſtructure, where the Ground is tolerably firm; but in Places where it is looſe and ſandy, it is a very good Method as ſoon as the Stakes are rammed, to pour in a good Quantity of Lime. This will ſlake gradually with the Wet, and mixing with the Sand, will become of itſelf a Kind of very firm Mortar, binding all about the Stakes in the Manner of a Stone.

When the Soil is not abſolutely ſandy, and yet is not ſo firm as might be wiſh'd, it is a good Way at firſt to put a Layer of Earth, and a Layer of Lime, and ſo work up the Foundation.

When the Stakes are thus driven, and the Ground is ſecured, let the Workmen begin to dig the Pond, whether that be to be done entirely, or Nature only to be aſſiſted in it.

Let the Earth they dig be thrown among the Stakes, and rammed well down, and thus laid in till they have entirely covered the Earth, being raiſed in a Bank above the Level of their Tops.

Another Parcel of Stakes are now to be driven in the ſame Manner as the firſt, and in the Interſtices between them; and the Earth that is dug is to be again laid in among theſe; and ſo, if needful, a third Parcel are to be driven, and filled up in the ſame Manner with the Earth that is dug. The Nature of the Situation is to determine this, and the Expence will be proportion'd to the making of this Head in Height.

This

This Head or Bank is not to be rais'd perpendicular, and all of a Thickneſs throughout; but ſloping upwards on each Side, in the Manner of thoſe Banks we have before directed to be made for the ſecuring Lands from the overflowings of the Sea. It is to be thickeſt at the Bottom, and ſmaller all the Way up: and the Slant on the Inſide muſt be made very ſmooth and even.

When it is thus carry'd up to a due Height, and the Sluice fix'd, and there is a Convenience for carrying off the waſte Water in Time of Floods, it is finiſh'd; and the reſt of the Work is cheap and eaſy. The whole String of Ponds are to be fabricated in this Manner, and they will always be managed afterwards with Eaſe and Convenience. It will alſo be a great Addition to the Work if a Side Ditch be dug, with Sluices out of each to it, for the emptying them ſeparately. For by this Contrivance any one of the Pond, may be emptied without diſturbing the others. This is a Contrivance we find mentioned by Dr. PLOT, as practiſed at STANTON HARCOURT, in OXFORDSHIRE; and it is ſo rational, that it muſt be well worth while to follow it in other Places.

The Head being made, we are to conſider the Conſtruction of the Body of the Pond. As to its Size, that muſt be proportioned either to the Nature of the Ground, or to the Quantity of Fiſh intended to be kept in it. But whatſoever be its Bigneſs, there are ſome unvariable Rules to be obſerved in its Conſtruction.

The Depth is a very material Article: for there are great Inconveniences attending the making it too deep or too ſhallow; and one Reaſon of the ill Succeſs of Fiſh Ponds in ſome Places is, that the Owners have taken them juſt as they found them, and ſome are too deep and others too ſhallow. A Clay Pit, or a Gravel Pit, may be capable of being converted into a Fiſh Pond; but he would be very idle who ſhould take them for that Purpoſe juſt as he finds them, and expect as much Advantage as if they were better form'd.

The proper Depth of a Fiſh Pond is about ſix Foot. It may be ſomething deeper without Diſadvantage, but no Pond ſhould be contrived to be of a leſs Depth than this, at middling Fullneſs.

We have obſerved already that the Ponds are to be of two Kinds, according to the Nature of their Water, the one for breeding, and the other for feeding of the Fiſh; and that this depends upon the Quality of the Water; the pooreſt being fit for breeding, and that which is moſt enriched by Additions, for feeding.

Therefore, ſuppoſing theſe Ponds to be all ſupplied by one original Spring riſing above the firſt; running through that, and thence into the others; it is plain that the Water of this Spring will be clearer, ſharper, and purer in the firſt Pond, into which it is received immediately from the Source, than in thoſe others into which it runs through that, and ſucceſſively through one or more of them alſo. Therefore in ſuch a ſtring of Ponds, the firſt or higheſt will always be fitteſt for a breeding Pond; and the laſt or loweſt fitteſt of all for a feeding Pond; and ſo of the reſt proportionally, thoſe will be fitteſt for breeding which are neareſt the firſt, and thoſe for feeding which are neareſt the other, or loweſt. This is a very material Diſtinction, for there ſhould be a Difference in the Conſtruction of the ſeveral Ponds, according to the Purpoſes for which they are intended.

One breeding Pond is enough to ſupply ſeveral for feeding: ſo that, in general, under ſuch a Diſtribution of Ponds in a Row, as thoſe here deſcribed, the proper Method will be to keep the firſt, or that which immediately receives the Spring, for breeding, and the ſeveral others that come next after it, for the Pike, Perch, and other Fiſh of Prey; and only the two or three laſt for feeding; which will receive their Water enrich'd by what it has collected in paſſing through the ſeveral others.

According to this Diſtribution, the firſt Pond ſhould be the leaſt deep of all: and ſhould have ſome Places particularly ſhallow, and contrived on Purpoſe for the receiving the Spawn. Its general Depth ſhould be five Foot; juſt at the Head it may be, for a little Way, five and a half, or ſix Foot; and the Head itſelf ſhould be carried down with a gentle Deſcent into that Depth, and toward the Water's Edge bottom'd with a clean Gravel. The Sides ſhould alſo, in moſt Places, go down with a very gradual Deſcent, and here and there be extended in Shoals, ſome of which ſhould have Stones and Gravel thrown over the Bottom; and the others left naturally. Theſe ſhallow Places ſerve for the Fiſh to ſun themſelves upon; and they lay the Spawn upon them, which in thoſe Places receives the Influence of the Sun, and is aſſiſted by it in the hatching into Life.

In general, Ponds that have a clean Water, and a gravelly or ſandy Bottom, are the beſt for breeding; as thoſe which have a ſoft or muddy Bottom are for feeding: and as this is known to ſucceed beſt in Nature, this is what Art ſhould imitate.

The middle Ponds, in this String of them, ſhould be of a ſomewhat greater Depth than the others, that the Pike, which grow large, may have a ſufficient Scope of Water; all Fiſhes naturally requiring this in proportion to their Magnitude. But it will be convenient alſo in theſe to let the Head deſcend gradually, and to have Shallows purpoſely left in ſome Places, as was directed in the breeding Ponds. Theſe will not only breed there themſelves, but their Food the Roach, and other ſuch Fiſh ſhould be encouraged to breed alſo. This they will do on theſe Shallows purpoſely left, and in this Manner ſuch a Supply will be rais'd, that the Pike and Pearch will find their Food naturally provided.

Laſtly, thoſe Ponds intended for feeding Carp, and ſuch other Fiſh, which are to be at the lower Part of the Row, ſhould have the common Depth of ſix Foot, in a Manner throughout; but it will be very proper to have here and there a little Iſland ſtanding in theſe; and in other Places to hollow away the Banks underneath, and to plant Willows, and other watery Trees along the Edges, that their Roots may bulge out into the Water. All theſe will ſerve to give Shelter and hiding Places to

the

the Fiſh, without which they will never thrive as they ought to do. Theſe Contrivances are very proper alſo for the middle Ponds in which the Fiſh of Prey are kept, for they love Holes and ſkulking Places more than any other: but in the breeding Ponds they are leaſt needed. Though in Moderation, Shade and Shelter are convenient every where. It is a very good Practice to ſink ſome ſmall Faggots in different Parts of the Ponds, when new dug, for they will ſerve the ſame Purpoſe of ſheltering, till ſome Weeds riſe in their Bottoms.

In all theſe Things the great Rule is Moderation. If too many Trees be planted on the Banks, they do a great deal of Harm by the falling of their Leaves into the Water; and too many, or too large Iſlands left in the Ponds, take up too much Room.

CHAP. XLIV.

Of the ſtocking of Fiſh Ponds.

WE have obſerved that our Huſbandman, who makes Ponds for the Sake of the Profit he is to gather from them, is to diſpoſe them in a Row, and form them according to the ſeveral Purpoſes they are to anſwer. We are to ſuppoſe him thus far advanced in his Deſign. He has, we will ſuppoſe, eight of them in this String, and has contrived the firſt for breeding of Carp and Tench, the ſecond for breeding Pearch, the two laſt for feeding his Carp and Tench, and the four middle ones for feeding his Pike and Pearch ſeparately, according to his Diſcretion.

The Ponds are prepared, and he is to ſtock them. The four Kinds already named are the Principal that he is to regard. Trout will not thrive in ſtanding Waters; in many they will not live, and in thoſe where they do not die at once, they languiſh and have nothing of their true Flavour.

Eels are very well worth keeping in Ponds, but they need not have any kept on Purpoſe for them. They are a Fiſh of Prey like the Pike and Pearch, and they may be kept in the ſame Pond with either, for they hide themſelves in ſuch a Manner, that thoſe Devourers cannot get at them: and they will thrive upon the ſmall Fry that are kept there for the Support of the others. They will grow to a great Size in theſe Ponds, but they are not like the Eel of the River for Taſte. The fineſt Eels in the World are thoſe caught in the clear and ſhallow Trout Rivers: theſe in Ponds have neither their Flavour at the Table, nor their Look while living.

Some put their Pike and Pearch into the ſame Ponds, imagining that the Pearch will eſcape the Jaws of the Pike, becauſe of his hard Scales, and prickly Fins, but this is a Miſtake. Where there is Plenty of other Food the Pike will let the Pearch eſcape, becauſe he prefers the Roach to him; but when Hunger calls upon that Fiſh, he is not nice in his Diſtinctions.

Some keep Fiſh of other Kinds in Ponds, as Chubs, Bream, Flounders, and the like, but they anſwer no profitable or uſeful Purpoſe. Where Fiſh are kept for the Table only, theſe are of an inferior Kind; and where the Price they will bring at Market is ſtudied, they are nothing in Compariſon of the others. A Bream is not good for any thing till it is of a very large Size, and it will never grow to this under fifteen or twenty Years, and requires very deep Water: and when it is at its Perfection few know that it is good; and 'tis not the pleaſant but the faſhionable Diſh, that brings the Money. If Gudgeons are kept it muſt be in the firſt Pond, where the Water is pureſt and cleareſt, but they come to nothing there; they are like the Trout, a Fiſh that naturally live in ſwift and ſhallow Rivers, and in Ponds they loſe their Colour and their Flavour.

Theſe Conſiderations fix the Huſbandman to the five Kinds of Fiſh already named, as the principal for his Purpoſe, and we have ſhewn in what Manner theſe are to be diſtributed in his Ponds. We now come to give him ſome Directions, ſuch as the concurrent Experience of all who have try'd confirms, for the breeding, feeding, and preſerving them in the moſt profitable Manner.

The firſt Pond has been ſet apart for the breeding of Carp and Tench, which may breed as well as live together afterwards, for they will neither hurt one another when grown, nor devour each other's Spawn as moſt of the other Fiſh will.

Carp is the moſt profitable Fiſh the Farmer can breed, and 'tis therefore fit we begin with conſidering them, and deliver what relates to them moſt particularly. No Fiſh bears a better Price at Market of all that he can breed; and none ſpawns ſo frequently. When we add to this, that the Carp is of very quick Growth, we have compriſed all that can be ſaid in the Praiſe of a Fiſh to the Perſon who keeps it for his Advantage.

The Carp will breed at much ſhorter Intervals than any other Fiſh, and the young are vaſtly numerous: they require little Care, and are ſufficiently hardy. The great Caution of the Farmer, in this Caſe, is to provide and keep up a ſufficient Number of Breeders.

The female Carp never begins to breed till about eight Years old. The Male need not be more than five Years. The Purchaſer muſt examine their Size and Condition, before he puts them into his breeding Pond, that he may not be diſappointed. Many have condemned the Nature of their Pond, when the Fault has been in the Condition of the Fiſh from which they expected their Increaſe.

The Proportion of the Males and Females ſhould be about one of the former to three of the latter; and not only a proper Number muſt be put in at firſt, but a watchful Eye muſt be kept that they do not decreaſe without Supplies, for the Carp often dies after ſpawning.

The Tench agrees in all theſe Reſpects with the Carp; and being put into the Pond with the ſame Regulations, the two Kinds will breed perfectly well together.

Into the ſecond Pond are to be put the Pearch for the ſame Purpoſe, and with the ſame Cautions. They will breed when they are kept in

the other Ponds, but they are ſo ravenous that they eat their own Offspring. And the only good Way of feeding them is when they are put into thoſe Ponds nearly of the ſame Size.

As to the Pike they will ſometimes breed in the Ponds where they are kept for feeding, but they more affect to do it in large Rivers. The Pearch will alſo breed in their Ponds, but in this Caſe few of the young come to any thing, for both Kinds feed upon their own. The Rule of putting in Fiſh nearly of a Size into the feeding Ponds, is as neceſſary to be obſerved with Reſpect of the Pike as the Pearch, for they will both devour ſuch of their own Species as are ſmaller. A Pearch of half a Pound weight will ſeize one of a quarter of a Pound; and the Pike will lay hold of ſuch as are very nearly as large as himſelf: he will prey upon any thing that he can get into his Mouth, no Matter whether he can ſwallow it. A Pike has been ſeen with a large one in his Jaws, ſwimming about till that Part which he had gorg'd was digeſted, that he might ſwallow the Remainder.

Theſe are ſufficient Reaſons why the Fiſh of Prey that are put into Ponds to feed, ſhould be as nearly as poſſible of a Size: and there is ſome Cauſe, though leſs, for the obſerving the ſame Rule with the others, for though they will not eat the ſmaller, they will ſtarve them by not permitting them to get any Food.

There is no Way of matching the Size of the Fiſh ſo well, as by ſupplying the feeding Ponds from the breeding ones. For in theſe latter thoſe Fiſh that are of the ſame Breed, muſt be equal in Bigneſs, and being put into the ſame Place, and having the ſame Food, they will keep up that Equality pretty nearly. As to the Pike, they are generally purchaſed, and the Care ſhould be to buy them, as nearly as poſſible, of a Size, for otherwiſe the Number will decreaſe continually. When Pearch are bought, the ſame Caution is to be obſerved for the ſame Reaſons. As to Eels, they need not be ſo carefully pick'd, for they are defended from the other Devourers, by their Place of Habitation, the Mud; and though they ſeize upon any other Fiſh that they can get at, they do not prey upon one another.

The Farmer muſt be cautious not to ſuffer his Geeſe or Ducks, with their young Brood, to come upon his Pike Ponds, for that voracious Fiſh will ſeize the young, while they are in the Down, as readily as he would a Roach or a Gudgeon.

When the Ponds are ſtock'd, the Owner ſhould take Care that the Herons do not get a way of coming there, and be particularly guarded againſt Otters, if there be any in the Neighbourhood. Theſe are the Enemies of his feeding Ponds; and there is one little regarded, but very deſtructive in thoſe that are for breeding, this is the Stittleback. As contemptible an Enemy as this may ſeem, none is ſo deſtructive of the Spawn and the young Brood, and none ſo difficult to be conquer'd. I have known many Ponds that would have been excellent for breeding, ſpoil'd by this little Creature: and even the emptying them is hardly a Security; for theſe ſmall Fiſh will live in the leaſt Quantity of Water that remains in any accidental Hollow, and they breed ſo quick, and in ſuch Numbers, that they ſoon are in a Condition to renew their Miſchief. They lodge about and under the Stones where the Carp and other valuable Fiſh depoſit their Spawn. They devour this wherever they find it, as their natural Food: and what eſcapes and hatches into Life, becomes their Prey in that Condition, for they are eternally catching the young Fiſhes.

There has been ſuppoſed a great Myſtery in the Matter of breeding Ponds; and the beſt Judges have been obliged to refer themſelves to Experience; only ſaying ſome will and ſome will not do for that Purpoſe, and there is no knowing but from Tryal. We have already named the wrong Age of the Fiſh, put in by ſome as Breeders, for one Reaſon of the failing; another is this little deſtructive Fiſh; and a third may be the ill-faſhioning and conſtructing of the Pond. But let theſe three Articles be managed rightly, and the Undertaker will ſeldom fail. Let the Pond be made according to our Directions, with Shallows for the Spawn; let Fiſh of a proper Age and Condition be put in, and let there be no Stittlebacks; and there will never fail to be a Supply for the feeding Ponds.

The next Thing to be conſidered is the Numbers to be kept in the feeding Ponds, and this muſt be proportioned, in part, to their Extent, and in part to their Richneſs. A rich feeding Pond, of an Acre Extent, will every Year ſupport very well two hundred Carps, of three Years old. If they be put in younger the Number is to be encreaſed in proportion, the ſame Pond will as well feed three hundred Carp of two Years old, or four hundred of one Year old. If the Pond be leſs rich, the Number muſt be ſmaller, and if of the richeſt Kind of all, it may be ſomewhat encreaſed.

Tench feed in the ſame Way as Carp, and may be put in after the ſame Manner: it is a very good Method to put in one third Part of the Number of Tench; or more, according to the Nature of the Pond: theſe two Kinds agreeing and feeding perfectly well together.

As to the Nature of the Pond ſuiting one or the other Kind, it depends in a great Meaſure, on the Soil at the Bottom. The Carp loves a loamy Bottom, and the Tench a muddy one. The Carp, in the ſame Manner, loves a new Pond, and the Tench an old one. The Carp is always found to thrive beſt where there are a great many Weeds, and good Shelter, and where there grows good Graſs about the Edges of the Water: the Tench, on the other hand, loves a deep Pond, with a warm owzy Soil and hollow Banks; and delights in the Cluſters of Flaggs that often run into the Water to a good Diſtance from the Shore.

Theſe are the particular Conditions that ſuit a Pond to the one or the other of theſe Kinds of Fiſh; and from this the Owner will be led to conduct himſelf to the beſt Advantage, according to the particular Nature and Condition of his Ponds. If they be nearly alike, let him put Tench and Carp together into each, and proportion them according to the Nature of the Pond, adding to or diminiſhing the Number of the Tench, as the Pond appears, according to theſe Circumſtances, to be more or leſs ſuited to them.

them. If on the other hand one of the Ponds be very well ſuited to Carp, and the other to Tench, let him put all his Carp into one, and all his Tench into the other.

Although Tench and Carp be freſh Water Fiſh, they will thrive very well where it is a little brackiſh. This is a Conſideration of great Conſequence to thoſe Farmers who are ſituated toward the Sea, or Salt Rivers. They often have Grounds of no great Uſe where Fiſh Ponds may be very well dug and ſupplied, but that the Water will not be perfectly freſh: they need not for this Reaſon be diſheartened from breeding Carp and Tench; for they will ſucceed full as well there as in the moſt perfect freſh Ponds: the only Diſadvantage is, that where the Water is too ſalt, they do not taſte ſo well as in the freſh Water feeding; but where it is only a little brackiſh, they thrive rather the better; and the Difference is not perceived in the Flavour.

CHAP. XLV.

Of feeding, preſerving, and taking Fiſh out of Ponds.

THE Farmer has now, we will ſuppoſe, put in his Stock of ſeveral Kinds into his Ponds; and he requires to know what there is more that he is to do in this Article of his Profeſſion. They are to be provided with Food, preſerved from Injuries, and at proper Seaſons taken out for the Market.

As to the firſt Article, their feeding, we have told him already that requires little Care or Charge. The Pike and Pearch in his middle Ponds are to be furniſhed with a Quantity of Roach, Dace, Gudgeons, and the like, the common Draught of every little River; but he muſt have his Eye upon them, that if they do not breed, which they frequently will, eſpecially the Roach, he muſt at Times throw in a freſh Supply. As to his Carp and Tench Ponds, they in a great Meaſure ſupply the Fiſh themſelves by the Richneſs of their Water, and by the Inſects and ſmall Animals that breed in them: but if at Times he throw in Grains, Blood, and the Offal of Chickens, their Guts, and the like, the Fiſh will feed the faſter. The ſame may be thrown into the ſeveral breeding Ponds; the Grains into the Carp and Tench Ponds, and the Offal into the Pearch.

This is all that is required on the Article of feeding, ſo that 'tis certainly as eaſy and as cheap as it has been repreſented.

As to the preſerving the Fiſh from Injuries, we have already named the keeping away Herons and Otters; and a farther great Care muſt be to keep off Thieves, eſpecially near great Towns, where there is a ready Market for what they ſhall ſteal: the keeping a good Watch, and the ſinking Things in the Ponds in a proper Manner to prevent the drawing of them, are the great Security. But there is another Accident to be named here by which great Numbers of Fiſh are deſtroyed, that is the Froſt.

People have ſeen that when the Water is altogether covered with Ice, the Fiſh languiſh, and if this continue a long Time they die. For this Reaſon they break the Ice, and uſe ſuch other Means to let in Air as they can, and this always has a good Effect: but there is one Thing farther Experience confirms, which is, that the Damage done by Froſt is much greater in foul Ponds than in clean. For this Reaſon the Occaſion of the Froſts doing Miſchief ſhould be prevented in Time. Ponds ſhould be frequently cleaned, which, as has been ſaid already, is an Article of Advantage to the Farmer rather than Expence, becauſe of the Value of their Mud as a Manure. When they are thus kept tolerably clean, the Froſt will have leſs Effect upon the Fiſh; and to prevent the Damage entirely, there ſhould be a few Pipes laid into the Water in different Places, with their Ends above its Surface. Let the Froſt be ever ſo ſevere, theſe will always keep a Communication with the Air, and with this Caution, and the Cleanneſs of the Bottom, the Fiſh will be perfectly well preſerved from Accidents.

Some lay in Straw for this Purpoſe, but its Effect is not ſo certain: that of a few Pipes is obvious, and cannot fail. The frequent cleaning of Ponds beſide this, is in all Reſpects ſerviceable to the Fiſh; and as it alſo ſerves the Farmers Purpoſe in a Supply of Manure, and anſwers its own Expence, there is all the Reaſon in the World to do it.

Laſtly, for the taking the Fiſh out of the Ponds, there require a few Inſtructions: they are very ſhort and eaſy, but the Neceſſity of them ſeems not very well known, for ſome Damage often happens for want of a Regard to them, and on ſome Occaſions a great deal.

In the common Way of taking Fiſh out with Nets, a great deal of Miſchief is done by Servants, hurting thoſe which are to be thrown in again, by Blows; and by keeping them too long out of the Water: and in the other Way of draining the Ponds, a great Diſturbance is made by letting the Water of one into another. Againſt this we have already propoſed a Method, by a Ditch cut along the Side of the Ponds, which every one who deals largely in Fiſh, will find vaſtly worth his while to practiſe.

Once in three Years every Pond ſhould be drained, and the Fiſh taken out and ſorted, removing the larger and the ſmaller than ordinary, to keep up that Equality which we have ſhewn to be ſo eſſential an Article in the Management of every Kind.

The breeding Ponds are to be drained as well as the others; and from them are to be taken the young Fiſh of proper Size for the Supply of the breeding Ponds, in anſwer to the Quantity that have been taken out. And when this is done, the Remainder are not to be thrown into the breeding Pond again, for they will ſtarve the Breeders: but they muſt be put ſomewhere to take their Chance, if they be not wanted on any particular Occaſion.

On this Occaſion great Care muſt be taken not to hurt the Breeders, either by Violence, or by keeping them too long out of the Water; and if the due Numbers be found deficient, they muſt be ſupplied with thoſe of a proper Age and Condition.

In this Manner the whole String of Ponds will be kept in good Order, and yield the greatest poſſible Advantage: there will be a conſtant Supply from the one to the other; and theſe Creatures will anſwer as regularly to the Farmer's Expectations, as any other Part of his Stock.

Whenever any Fiſh are taken out for Sale, the Maſter's Eye ſhould be over the Draught for two Reaſons; it will keep in his Mind a due Knowledge of the Condition of his Stock, and he will ſee that no Hurt is done to ſuch as are to be put in again.

We ſhall now add a few Obſervations in a general Way, and then cloſe this Article.

If it happen that the Farmer have Convenience of digging a Pond where it ſhall have a marley Bottom, he may be ſure of feeding Carps there to a very great Advantage. If he have Opportunity alſo of making a Pond in ſome Place where it ſhall receive the Waſhings of Sinks, or the Foulneſs from great Houſes, or about large Towns, he may be ſure in the ſame Manner, that both Carp and Tench will grow and fatten there in a ſurprizing Manner. If he have the Opportunity of making a Pond at the Head of a chalky Spring, he may feed Trout in it, and this is the only Condition of a Pond that can ſuit it to that Fiſh: but even here they will not ſucceed as in Rivers. If the Pond be dug in a Bed of Clay, or if he be obliged to clay it in order to make it hold Water, and it be found too cold for the more valuable Kinds of Fiſh, he may breed Flounders in it. They will take Care of themſelves, and will grow to a great Size in it. They ſeem to thrive in ſuch Ponds better than in Rivers, but their Taſte is not ſo fine.

When Ponds are to be made in boggy and ſpringy Places, where Carts cannot well come to get away the Mud thrown up in cleaning them, the beſt and moſt advantageous Method is to dig them long and narrow, like Ditches rather than Ponds, that the Workmen may be able to throw out the Mud on either Side at a ſingle Throw.

The Pike grows ſo faſt, that it is very well worth the keeping in feeding Ponds, becauſe of the quick Increaſe in Value. Pike of ſix Inches long may be had for a very ſmall Price near large Rivers, and if put into Ponds with Plenty of Food, they will grow to fourteen Inches length the firſt Year, and the next to two or three and twenty Inches. If the Owner have a mind to fatten them, nothing anſwers the Purpoſe ſo well as Eels chop'd to Pieces: they will devour theſe greedily, and fatten upon them like Pigs. When the Pike grows to a good Size, and is in due Condition, he bears a good Price, but the conſtant and marketable Fiſh is the Carp. It is on this the Perſon who intends to make Advantage of his Fiſh Ponds, ſhould principally rely for it; for none requires ſo little Trouble, or is liable to ſo few Accidents.

Among the ſeveral Kinds of Fiſh that he can keep, there is none ſo ſafe from the common Accidents as the Carp. It will endure Hardſhip of Froſt and other Kinds, better than any; it is ſhy in a great Degree, ſo that it preſerves itſelf from common Enemies, and no Fiſh is more difficult to be taken out by the common Methods of ſtealing. They will not readily bite the Hook when grown to a Size, eſpecially in Ponds of the rich Kind, that have been recommended for the feeding them; and even the caſting Net rarely ſurprizes them. They have a Way of plunging to the Bottom upon the firſt Notice of any Diſturbance in the Water, and their Way is to ſtrike their Heads into the Mud. In this Caſe the Net draws over their Tails, without laying hold of them. No Fiſh is therefore ſo ſecure to the Owner, nor any of ſuch certain Sale in all Places.

BOOK V. PART IV.

Of INSECTS.

CHAP. XLVI.

Of Bees, their Nature and Products.

AMONG the Inſect Kind there is but one Species with which the Huſbandman at this Time has any Concern. That is, the Bee, A Creature which has this great Recommendation to his Notice, that is, to be kept with very little Expence, and leſs Trouble; and which at the ſame Time yields him two Commodities that are always marketable, and always bear a conſiderable Price, Wax and Honey.

Volumes have been written on the Bee before its Nature was ſo well underſtood as it is at preſent: Volumes therefore might be added, for with the more perfect Knowledge of its Nature, we have arrived at the Diſcovery of many other of its Properties: but we do not in this Work intend any where to expatiate for the Sake of an idle Curioſity. That it is the Intereſt of the induſtrious Huſbandman to keep Bees is plain, becauſe they will bring him Profit, and naturally fall in the Way of his Profeſſion; this therefore we recommend to him: and that he may be able to do it in the moſt advantageous Manner, we ſhall, as on all other Occaſions, lay down the beſt Rules Experience has ſhewn for that Purpoſe. And as we have endeavoured to explain to him every Article of his Buſineſs, that he might always not only know what he ought to do, but why he was to do it; we ſhall in the ſame Manner lay before him in a few plain Words, on Account of this Creature, ſo far as he needs to know it, with the Nature of thoſe Products which it offers to his Service.

The Antients ſuppoſed Bees to be produced from the corrupted Fleſh of Animals, and they pretended to lay down Methods of procuring them

them by this Means: but all this is known to be an Error. Virgil adviſes the killing of a Bull Calf, and expoſing its Fleſh in a particular Manner for the breeding of Bees in it; but there is no more Truth in this than in Sir Kenelm Digby's Receipt to make Crawfiſh, by burning and beating to Pieces others.

We know at this Time that all Creatures, the leaſt as well as the greateſt, are produced from the Eggs or Embryo's of their Parents, and that they can be produced in no other Manner.

In the Generation of Inſects, Nature obſerves this conſtant Method, that all ſuch as have no Wings, are produced from the Eggs of their Parents, or brought forth alive in their own Forms, whereas all thoſe which have Wings undergo a kind of Change. Theſe are hatch'd from the Eggs of their winged Parents, in form of Caterpillars, Worms, or Maggots; in which they live a certain Time, and then fall into a State of Reſt, covering themſelves with a Web or Caſe of their own making; or ſhrinking into their Skins which harden for that Purpoſe: and after they have lain a certain Time thus, they break forth in the winged Form like their Parents.

This has been ſuppoſed to be much more wonderful than it is; the vulgar have thought that it was a Change of one Creature into another; and the learned have adopted the Folly, as it were, under the hard Word Metamorphoſis of Inſects. But the Truth is, the Butterfly is in the Caterpillar, and only takes that Time to grow to its due Perfection.

As this is the Caſe with all winged Inſects, the Bee being one of them, muſt have its Origin in the ſame Manner, and the Method is this. When the Combs are made, a Female Parent lays an Egg in every Cell, theſe Eggs hatch into a Kind of white Maggots, and after theſe have lived their Time, they fall into a State of Reſt within the Cell, and in due Seaſon the Bee burſts forth, and takes its Flight.

There is this very ſingular in Bees, that they are of three Kinds. In the Generality of Animals there is a Male and Female Sex, and no other Difference; but among Bees, there are Males, Females, and others of no Sex at all.

Theſe laſt are the great Number, and go through all the Drudgery. The Males are but a moderate Proportion, and when they have performed their Office in impregnating the Females, they are driven out of the Hives to periſh. The Females are very few, but each lays a vaſt Number of Eggs, and they are always taken great Care of in the Swarm. They are diſtinguiſhed from the others by their Size and Shape, and have been called by the Names of Kings and Queens of the Swarm.

The two valuable Subſtances with which the Bees ſupply the Farmer, Wax and Honey, are both extracted from the Flowers of Plants. The Wax is ſomewhat altered by the Creature to bring it to that State, but the Honey they find in its own Form.

In the Flowers of Plants there ſtand up certain ſlender Threads, with little Lumps upon their Tops. Theſe are in ſome more, in others fewer, and upon the Number of them is founded the preſent faſhionable Method of claſſing Plants. Theſe Lumps or Knobs which ſtand thus in the Centre of the Flowers, contain a fine Duſt, which ſerves to impregnate the Seeds of the Plant: but as Nature frequently provides for many Purpoſes in the ſame Thing, this Powder or Duſt which is formed in a much greater Quantity than it is wanted for the Service of the Herb, aſſiſts the Bee for its Combs, in which to depoſit its Honey and its young, furniſhing the Materials of which Wax is fabricated by the Creature.

Toward the Bottoms of ſome Flowers, and at the Bottoms of others, there are alſo certain Cells, or Lodgments of different Kinds, Shapes and Forms, in the which is held a ſweet Juice: this is Honey. This the Bee takes out, and has nothing more to do than to remove or carry it to its Cells.

This is the real and certain Origin of Wax and Honey. The Bee feeds upon the Duſt which is found in theſe Lumps in the Centre of Flowers, and afterwards diſgorges it for the Service of the Hive. It affords ſome Nouriſhment to the little Body of the Inſect, and after that is carried off, and the Reſidue has undergone the Operation of the Creature's Stomach, it is Wax. With this the Combs are formed of that beautiful and uſeful Figure, and in the Cells of theſe is depoſited the ſweet Juice, which they collect from the Bottoms of Flowers, and which, without any Aſſiſtance from them, is Honey.

This is the Hiſtory of that ſurprizing Inſect the Bee, and thus much it is fit the Farmer ſhould be acquainted with, for the reſt it is matter of Curioſity, rather than of Uſe; and a great deal might be ſaid very prettily, but very uſeleſly with Reſpect to him on the ſeveral Subjects. After this ſuccinct Account of the Creature, and the Origin of its Products, we ſhall enter upon the uſeful Part; the beſt and moſt advantageous Methods of managing them.

CHAP. XLVII.

Of Hives, and the Manner of placing them.

THE Bee in the natural Courſe and Conduct of its own Life, joins its Fellows, which collect together into a Swarm, and make of the Wax they thus collect and prepare from the Duſt of Flowers, certain Cells, which being joined one to another, form the Combs; and in theſe Cells they depoſit the Honey they take from the Bottoms of the ſame or other Flowers.

In their State of Nature they place theſe Combs in the Hollow of a Tree, or ſome ſuch Cavity, into which the ſmaller Entrance the better for their Safety: in order to make the moſt commodious Advantage of their Products, Men have contrived Places of Reception for their Combs, into which they tempt the Bees to come. Theſe are Hives, which in different Places, and at various Times, have been contrived to be made of ſeveral Forms and Materials; but the uſual Kind at preſent are made of twiſted Straw, and none anſwer better. A great

many Sorts have been deviſed for Pleaſure, and the Curioſity of ſeeing them work; but for the plain Uſe and Advantage to be had from the Creature, none anſwers better than this common Kind, nor is any other worth the Huſbandman's Regard.

There have been many Contrivances of late to ſave the Bees when the Honey is taken; but theſe are not neceſſary; for a proper Management with the common Hives, placing one over another for the Reception of the Creature, will anſwer all the ſame Purpoſes. We do not ſay that this will anſwer all the Purpoſes that are pretended to be anſwered by the others: but all that they really effect.

The Form and Faſhion of the common Straw Hives is ſufficiently known; but they are often made too high for their Width. The beſt Size is ſuch as would hold about ſix Gallons, and the Huſbandman will do well to order theſe to be made a little more ſquat than the common Practice allows.

Beſide theſe there ſhould be ſome of a ſmaller Size for the multiplying the Stock of Bees, and receiving the little Swarms; and it will be right to have a few larger, that they may be in Readineſs for an extraordinary large Swarm.

The Hives muſt be trimmed as ſmooth and even as may be, cutting off all ſtaring Straws, and the Spleets are to be then put in, three or four deſcending from the Top to near the Edge, and a Couple of others to ſupport the Opening or Door, and two more behind: theſe laſt are to be thruſt firmly into the Subſtance of the Hive, to keep it from ſinking when it is full.

The Hives being thus prepared for the Reception of the Bees, the next Conſideration is that of finding a fit Place for ſetting them: for the Bee is tender in its Nature, and the whole Work will proceed greatly the better, for a little Care in the ſetting out.

Let a Spot be choſen not far from the Houſe, and well defended from Winds every Way. The beſt Security of this Kind is by proper Hedges; and theſe ſhould be ſo contrived as not to keep out the Sun; for the Bee requires Warmth, as well as Stillneſs. The Place muſt be well defended againſt Cattle, both for the Bees Sake and their own; for theſe little Creatures hate Diſturbance, and they generally reſent it very ſeverely. The beſt Situation is when the Houſe, or ſome large Building, ſtands to the North, that it may be perfectly defended on that Quarter, and the Opening is to the South, to let in the beſt Rays of the Sun. There ſhould be alſo ſome Trees pretty near to receive them at the Times of their ſwarming.

The Place being thus choſen, let there be ſet up a Parcel of Stools for the Hives to ſtand upon. The uſual Method is to ſet ſeveral together on a Bench, but it is not ſo well. It occaſions a great deal of Confuſion among the Bees, who often miſtake one Hive for another, and in Winter they will quarrel about it, and do one another a great deal of Miſchief.

The Stools ſhould be made of Wood, for when cover'd with Stone they are too hot in Summer, and too cold in Winter. They ſhould be raiſed about a Foot, or a little more from the Ground, and placed not exactly upright, but a little ſlanting, that the Water which falls on them may run off. On the Top they ſhould be about an Inch broader than the Bottom of the Hive; and in Front juſt before the Door of the Hive, they ſhould have an Extent of the Bigneſs of one's Hand for the Bees to ſettle upon when they come home loaded. Theſe Stools ſhould be ſet in a Row from Weſt to Eaſt, and they ſhould point South, a little inclining to the Weſt, that the Body of the Hive may break the Eaſt Wind from the Door.

For yet farther Security, theſe Stools, with the Hives upon them, may be incloſed in a little boarded Building, either ſingly, or ſeveral of them together; which may have a tiled Covering to keep off wet, and Doors to ſhut or open according to the Severity or Mildneſs of the Seaſon.

This is not a Thing of abſolute Neceſſity, for People keep Bees to a great Advantage without ſuch Trouble; but it is right, and what I would adviſe the Huſbandman to do; for the Expence is little; and in this, as in every other Article of his Stock, thoſe Things which will of themſelves ſucceed very well, will bring him in larger Profits in Proportion to the Care he beſtows upon them. In general, whatever Methods are uſed to guard againſt the Things that injure Bees, the two greateſt of theſe are cold and wet; and of thoſe two the latter is the greater.

The Winter is the Seaſon in which Bees are moſt liable to Injuries; but theſe they in a great Meaſure eſcape if their Hives be well made, and well defended, and they will keep within them. Any Thing of a Building about the Hives ſerves to darken as well as to ſhelter them; and this in Winter is of great Service, for it prevents their going out at every Time when the Sun happens to ſhine a little, which they otherwiſe are too apt to do, and ſo are killed by the Cold while they are abroad.

It is for this Reaſon the greateſt Number of Bees periſh in the mildeſt Winters. This ſounds odd, but they keep within the Hives in very ſevere Seaſons, and are there ſafe, whereas they go out in theſe mild Days and periſh.

When Bees are thus kept duſky and ſheltered during Winter, the Doors are to be thrown open early in Spring, to promote their Induſtry and their Breeding.

At the Time of the Bees ſwarming, the Hives intended to be uſed are to be rub'd with Thyme, Hyſſop, or Bean Tops, which will pleaſe the Bees, and it is a good Method to rub a little Honey on the Inſide.

The Hives are to be plaiſtered down to the Stools with a Mixture of Cow Dung, Sand, and a little Lime, this muſt be carried round the Edges to keep all cloſe, and fence out the Wind; and in the Winter the Door of the Hive ſhould be ſtopped with a ſmall Piece of Board that has two or three Notches in it to let the Bees through, and not large enough to let in any Thing that would hurt them.

CHAP. XLVIII.

Of the ſwarming of Bees.

WHEN the Bees encreaſe, ſo that they are too many for the Hive, they naturally ſwarm. The Time of their doing this is the Beginning of Summer, and this is a Seaſon at which the Owner is to watch them with a particular Care, for the Encreaſe of his Stock and his Profit depend principally upon his Management at this Juncture.

It is plain that the Fullneſs of the Hive is the Reaſon of their ſwarming, becauſe they ſometimes get a Way of lying out of the Hive, under the Stool or behind; and in this Caſe, not perceiving the Hive to be full, they will not ſwarm, although their Number is greater than in other Hives where they ſwarm, becauſe they keep within.

The ſwarming of Bees depends upon many Accidents, and none more affects this Article in their Œconomy, than the Weather. In a mild and calm Spring they ſwarm early: in a cold and backward Seaſon they do not ſwarm well; and what they do in it is later.

Toward the Middle of May, if the Seaſon favour, the Owner is to watch the Hives to be prepar'd for their ſwarming. When the Drones are thrown out early, it is a Sign the Hive is full; and when, after this, the Bees are ſeen continually in Cluſters about the Door, and often lie out; and when there is ſome Moiſture about the Foot of the Hive, at times, and they hover in great Numbers together round the Door, it is always a Sign of ſwarming. When there happens a warm Gleam of Sun, after a ſlight Shower in the Middle of a calm Day, they may be expected to take that Opportunity of riſing; and if, juſt after this, they be ſeen hanging in Cluſters, about the Door of the Hive, it is to be immediately expected.

If the Weather prove ſtormy when the Bees are ready to ſwarm, it will prevent them; and if this happen from time to time, they will be put off entirely, and the Opportunity loſt for that Seaſon. Sometimes alſo, in extreamly hot and dry Weather, they will be ſo continually out, and ſo many of them together, that not perceiving the Fulneſs of the Hive, that alſo will prevent them from ſwarming.

As their own Senſe of the Fulneſs of the Hive is a great Reaſon of their ſwarming, the Owner ſhould take all Opportunities to force them in, in good ſwarming Weather, when they lie out at the Door. He ſhould alſo ſhade and cool the Hive at theſe Times, if the Weather be very hot. At the ſame Time, if thoſe which hang about the Stool be gently mov'd off with a Bruſh, it will cauſe them to riſe, and the Noiſe of ſeveral of them flying up together, will ſometimes call up the others, and make them ſwarm.

When the Bees lie out in great Numbers it is a good Method to raiſe up the Hive, and let them all in, and then faſten down the Sides with Cow Dung and Sand beat up together, leaving only the Door open. This will make them perceive the Fullneſs, and they will often be led to ſwarm almoſt immediately.

The good Women have many idle and ſuperſtitious Cuſtoms for making Bees ſwarm: but theſe are founded upon Reaſon, and the Nature of the Inſect; and if theſe do not bring them to it, they will rarely be made to do it any other Way.

One Swarm not ſufficiently unloading the Hive, at eight or ten Days Diſtance, there is another ready. Theſe are what they call After-Swarms, and they always know of their coming out by the Noiſe. They ſeem to call one another forth with a ſharp and ſhrill Note, and preſently riſe in Numbers.

When the firſt Swarm happens to be broken, the ſecond will ſometimes come the next Day, and after this there will come a third, and ſometimes a fourth: but all this uſually happens within fourteen or fifteen Days.

There is no Subject on which the Country People have been more ſuperſtitious than this of Bees, but we wiſh to break through thoſe idle Cuſtoms. One of theſe is, that as ſoon as the Swarm is riſen, they ring upon a Kettle or Pan, and make as loud a Noiſe as they are able; they imagine this aſſiſts the ſwarming, and brings them down, but nothing is more contrary to Reaſon. Their ſwarming is an Operation in the Courſe of their Nature, and all that is to be done is to let them be quiet while they are about it: all Noiſe diſturbs them, and they ſhould never be interrupted. If there be any Danger of their wandering, a little Duſt is to be thrown among them, and it never fails to quiet them, and bring them down.

The beating upon Kettles and Mortars was probably invented only as a Signal to the Neighbours, that ſuch a one's Swarm was up; they who invented it did not know that it was of ill Conſequence, and they have been followed in it by thoſe who have imagined it to be uſeful.

Sometimes one Swarm of Bees will caſt another in the ſame Year; this is an Article of which the Huſbandman cannot be ſo well aware, as of the firſt and more certain ſwarming; but he is to watch as ſoon as he ſees the firſt Signs of it, and follow them in all Reſpects as the firſt Swarms, getting them into an Hive according to the Directions to be given in the ſucceeding Chapter.

When it happens that the Swarm parts, he is to conduct himſelf according to the Diſtance at which the two Bodies ſettle.

If they be within Sight of one another, the beſt Way is to diſturb the leſſer Cluſter, and they will riſe and go to the greater: if they be out of Sight they muſt be hived ſeparately.

CHAP. XLIX.

Of the hiving of Bees.

WE have, in the preceding Chapter, directed the Huſbandman in what Manner to prepare his Hives for the Reception of the Bees: theſe being ready, he is to get them into them

in

in the following Manner. He is to watch the Swarm till they have fix'd upon the Place where they ſhall light: they ſoon begin to cluſter together there, and when they are clung one to another, and well ſettled, and the whole Company are met, they are in a Condition to be got into the Hive.

According to the Bigneſs of the Swarm he is to chuſe a larger or ſmaller Hive, and his great Care is to get them properly into it. The Bee is a Creature that will bear ſome Diſturbance without Reſentment, but they muſt not be too far ruffled; when they are angry their Sting is a very ſevere Weapon. It may always happen that ſome of them may be provoked in this great Article of hiving, and for that Reaſon the Perſon who undertakes it ſhould be prepar'd againſt the Danger. Let him have a Net wove, with the Meſhes ſo ſmall that the Bee cannot get through them, and large enough to be put on over his Hat, and fall down upon his Shoulders. His Face and Neck will be thus perfectly defended, and he will be able all the while to ſee what he is doing: let him put on a thick Pair of Woollen Stockings, and a Pair of Gloves of the ſame Stuff, which it will be beſt to draw up pretty high upon his Arm. When he is thus defended, let him go to work ſedately and ſoftly, for any haſty Motion diſturbs and angers the Bees.

Let a Cloth be ſpread upon the Ground near where the Bees are ſettled, and the Hive laid upon it. Their common Place of alighting is the Bough of a Tree, and if this be a ſmall one let the Huſbandman approach ſoftly to it, and gently cut it off; let him take it down quietly and lay it upon the Cloth, and ſet the Hive over it. This is the moſt familiar and eaſy Way, and none ſucceeds ſo well: when the Bees have ſettled upon a larger Bough, or otherwiſe diſpoſed themſelves, ſo that this Method cannot be taken, the Huſbandman is to ſhake them off into the Hive, and then to ſet it upon the Cloth ſpread for that Purpoſe. If they happen to light near the Ground, the beſt Way is to draw the Cloth under them, and then ſhaking them off, cover them with the Hive. When any Number gather at ſome little Diſtance from the Hive, he is to move them gently toward it with a Bruſh; and if they take to any other Place, he is to wipe them off with the Bruſh, and rub the Place with ſomething diſagreeable to them, as Wormwood, or ſtinking Mayweed. Finally, the Swarm is to be ſet as near as can be to the lighting Place, and all left to be quiet.

Sometimes the Swarms come late, and are ſmall, the beſt of them not ſufficient to fill the leaſt Hive, in this Caſe the Huſbandman is to put two or three of them together in one Hive; for otherwiſe they will be poor, and liable to Accidents, and will rarely come to any thing. If two or three of theſe follow one another, though not on the ſame Day, ſtill let him take them one after another into the ſame Hive, and by thus joining them, and forming a tolerable Body, they will become induſtrious and be able to defend themſelves, which ſingly they would not do.

The Method of joining theſe ſeveral little Swarms is this. Near the Stool where the united Swarm is to ſtand, ſpread a Cloth upon the Ground in a calm ſtill Evening, when it grows dark; then ſet two Supporters for the Hive, and knock down the Hive out of which the Bees are intended to be removed; then lift it up, and clapping it between the Hands, to get out the Bees that ſtick to its Sides, lay it down on one Side by the Bees; and over them ſet the Swarm to which they are to be added, placing the Hive upon the Supporters. They will immediately riſe into this Hive, where they will join the Bees that are in it; and if any remain about the empty Hive, it is only diſturbing them, and they will follow the reſt, and the two Swarms will become perfectly one. In this Manner alſo another Swarm may be added to them, and one Hive may be thus well fill'd with thoſe Swarms, that would have ſucceeded very badly in two or three. When the Bees are all got in, let the empty Hive be taken away, and the full one plac'd upon a Stool that Night, or the next Morning early.

There is another eaſy Method of uniting two Swarms, or more, which is this. Let the Hive into which a ſmall Swarm has been taken, be turn'd Bottom upwards, and in that Manner fix'd to the Bottom of the other Hive with its Swarm, faſtening up the joining of the two. The Bees in that which is undermoſt will fly up into the other, and then the lower one may be taken away. In this Manner a ſecond or third ſmall Swarm may be added to the firſt, till it be encreaſed to a proper Quantity. But this muſt be done before the Bees have begun to make Combs in the Hive they are removed from; for when they have once ſet to work they are unwilling to quit it. For this Reaſon whatever Method be taken of joining of Swarms, the ſooner it is done always the better.

Leſs Time is to be ſuffer'd to paſs on theſe Occaſions, than thoſe unacquainted with the Nature of Bees might imagine, for as ſoon as they are ſettled in the Hive they get to work, and in a very few Days they make a ſurprizing Progreſs, forming in that Time large and compleat Combs.

When an old Stock of Bees is to be removed from one Place to another, a proper Seaſon, and a proper Day are to be choſen for that Purpoſe, and it is to be done with a great deal of Caution. The Beginning of OCTOBER is the beſt Time, but it may be done in FEBRUARY, or any Time in the Winter; but fair and ſtill Weather ſhould be choſen for the doing it; and an Evening is the beſt Time, when the Bees are quiet.

CHAP. L.

Of the preſerving of Bees.

THE Bees, for the greateſt Part of the Year, provide perfectly well for themſelves; but in hard Seaſons they are to be aſſiſted, they will repay the Owner's Trouble with Intereſt, and the Food he is to give them is not expenſive, when the Smallneſs of the needful Quantity is conſidered.

One Article that makes this the leſs expenſive is,

is, that the Number of Bees at the Time when this is wanted, is not nearly equal to what it is at other Seaſons of the Year. 'Tis only in Winter they require Aſſiſtance, and their Number is by that Time greatly decreaſed by their Deaths, ſince the Time of their ſwarming. A great many die toward Autumn, and many more as the Weather grows more ſevere, ſo that by that Time they want Food, the Number is much reduced that is to eat it.

Beſide, the feeding them in Winter when their own Store fails; it is often very proper to do it in Spring, when the Stock of Honey is ſmall, and the Quantity of Bees large, as will ſometimes happen at this Seaſon from unfavourable Weather. Nothing is then better worth while than to feed them; and the beſt Way of doing this, is by conveying the Food in a Cane, or little Trough, into the Hive. Many Kinds of Food have been contrived for them, but the beſt I have found on repeated Experience, is a Mixture of Honey with ſweet Wort, or new Beer, and a little Bay Salt: this not only gives them the needful Supply of Nouriſhment, but always makes them healthy and vigorous. Some give Bread ſopped in Ale, and they will eat it greedily: the Honey is, however, certainly the beſt, becauſe it is the moſt natural Food: the Mixture of Salt I firſt tried, from obſerving that Bees ſucceed better in the Neighbourhood of the Sea, or Salt Rivers, than in any other Places; and ſince the Succeſs of this Food, I have always made it a Cuſtom to ſet a Pan of Water, with a little Salt in it, near the Hive.

The Seaſon of Spring feeding is in March. This is the Time when they begin to breed, and if they have had a bad Seaſon and want Food, they cannot attend as they ought to do, to the great Affair of producing their Young, which is of all Conſiderations relating to them, the moſt important to him who wants to increaſe his Stock.

The Bees that want Food in the Winter very often do not deſerve it; but theſe always repay the Obligation largely.

We have ſhewn the Huſbandman what Methods he is to uſe for the keeping his Bees alive at all Times, and making the moſt of their ſeveral leſſer Swarms; but we are yet to remind him of guarding them againſt ſuch Things as are naturally offenſive to them; and preſerving them from many Things that would deſtroy them.

Quiet is a great Article in the Care of Bees, therefore all Noiſe and Diſturbance are to be as much as poſſible kept from them. We have already directed that Cattle ſhould be kept away by good Fences, and for this Reaſon the Place of their ſetting them ſhould be far from publick Roads, or Cartways.

Smoak is very deſtructive of them, and they are always to be carefully defended from it, eſpecially that Smoak which riſes from the burning any Thing upon the Ground, for it is eaſily driven by the leaſt Wind juſt upon them, being on their Level, and it choaks and deſtroys them. All bad Smells alſo do them Harm, and render their Habitation diſagreeable.

After theſe Conſiderations, he who keeps Bees is next to take Care that they be not expoſed to the Inſults and Deſtruction of their ſeveral Enemies, Field Mice will deſtroy them, and Birds of many Kinds will devour them: Care muſt be taken to deſtroy and keep theſe away.

In Years wherein Waſps and Hornets are numerous, they do great Miſchief, entering the Hives, and plundering them of the Honey; but it is eaſy to guard againſt theſe, by ſetting Viols of ſweeten'd Cyder near the Hive, nothing tempting the Hornet and the Waſp ſo much.

Beſide theſe foreign Enemies, the Bees are often very troubleſome, and deſtructive to one another, by fighting. One Way to ſtop this Miſchief is by cloſing up the Hive: but if Matters be too far gone to admit this Remedy, the ſprinkling a little Duſt among them anſwers the Purpoſe.

CHAP. LI.

Of taking the Honey and Wax.

THE Huſbandman keeps Bees for the Sake of their Honey and their Wax. He has ſeen the neceſſary Methods of feeding and preſerving them; we now come to the Article which is his immediate Concern, the making his Advantage of their Products.

Of the Wax they make their Combs, and in the Cells of thoſe Combs they depoſit their Honey. The Wax not being eaten would remain uninjured in the Hive during the Winter; but this is not the Caſe with the Honey. It is the Store they lay up in Summer for the Proviſion of that Seaſon; and the Way for obtaining it in the largeſt Quantity, is to find the exact Time when the Combs are fulleſt.

All the Summer they are collecting Honey: in August the Combs are fulleſt, and from that Time the Bees often eat more than they get, ſo that the Quantity decreaſes. This points out the End of August very plainly, as the Time at which there is moſt Honey in the Hive: that therefore is the proper Seaſon for taking it.

The old Way is to kill the Bees, and take their Produce at this Seaſon: but many Methods have been invented for ſaving them. However, as there is not any great Purpoſe anſwered by preſerving them when their Food is taken away, unleſs more Care and Trouble be taken about them, than it is worth the Farmer's while to beſtow; I ſhall adviſe him to follow the old Method, and deſtroy the Swarm when he has taken their Stores. This Practice is not ſo cruel as it appears, for the Life of the Bee is very ſhort naturally; and with the beſt Management they paſs but an uncomfortable Winter after they are robbed of their natural Proviſion.

At the End of August therefore let the Huſbandman conſider what he will keep, and what he will kill. In this he is to be directed in a great Meaſure by the Age of the Swarm, the beſt to keep being thoſe of one or two Years ſtanding; or thoſe of three or four Years, which, by Reaſon of their ſwarming the laſt Summer are full of Bees, and are the moſt likely to be good. The Swarms of three or four

Years old which have caſt Hives are to be killed, becauſe they are not like to continue; as are alſo thoſe poor Swarms that are not worth the feeding; and all light Stocks, and ſuch as do not carry out their Droſs, or drive away the Drones in good Time. Theſe are the principal Rules for the Farmer's Conduct in this Matter, and to theſe may be added, that he ſhould take for killing all ſuch as are three Years old or upwards, that have miſſed ſwarming the two preceeding Years, and ſuch as are weak and eaſily plundered. Theſe are the Directions he is to follow in the taking them, and he is not to omit the Temptation of a large Store, whatever be the Condition of the Hive: therefore if he perceive any to be very full, as they will ſometimes in good Years be down to the Bottom, he muſt take theſe, for they never can be better, and often one ſuch Hive is worth three.

When the Hives that are to be taken for the Honey are marked, let there be a Hole dug in the Ground of about nine Inches deep, and nearly of the Bigneſs of the Bottom of the Hive, with the fine Mould piled up round the Brim. Having this Hole prepared, about two Hours before Sun ſet, take a Brimſtone Match as long and thick as a large Skewer, fix it in the Slit of a ſmall cleft Stick, with a ſharp Point. Stick this in the Ground at the Bottom of the Hole, ſo that the Top of the Match may come within an Inch of the Level of the Rim: if one be not thought ſufficient, another may be added, prepared in the ſame Manner. Let the Top of each Match be lighted, and then ſet the Hive over the Hole. Draw the fine Mould about the Edges to keep in the Smoak, and thus let it ſtand a Quarter of an Hour. In that Time the Bees will be all dead.

The Hive is now to be taken into the Houſe, and the Combs are to be carefully ſeparated, taking them out one by one. The dead Bees are to be bruſhed off with a Feather, and when that is done, the Combs are to be broke each into three Pieces.

There will a good deal of Honey flow naturally out of theſe, and this is to be kept by itſelf. It is called Virgin Honey: but the ſame Name is alſo given to the firſt Honey of any Swarm. Let this Honey be put in a Pot, and ſet by two or three Days; in this Time if there be any Mixture of Wax or other Foulneſs among it, that will work to the Top in a kind of Skum, and is to be taken off.

After the Combs will run no longer, they are to be preſſed, and this Way they afford a large Quantity of what is called common Honey. The Combs after they have been thus preſſed, are to be waſhed, and when all the Sweetneſs is out of them, they are to be worked for Wax. The Liquor in which they are waſhed, and the coarſer Part of the Honey, are uſually made into a kind of Mead.

The waſhed Combs are to be ſet over the Fire in a large Kettle of Water, and boiled, ſtirring it continually about to prevent burning to the Bottom or Sides of the Kettle. When the Wax is well melted, pour all into a Strainer, and immediately put it into a Preſs, ſetting a Veſſel of cold Water under it; into this let the Wax fall; and let the Preſſing be continued a long as any Wax can be forced out.

When all is thus got that will come, let it be taken out of the Water, and moulded and worked up into Balls in the Hands; and after this let theſe Balls be broken to Pieces, and ſet over a gentle Fire to melt. Let the Wax be ſkimmed as the Froth riſes, and when thoroughly melted, and well ſkimmed, let it be ſtrained ſlowly through a Canvaſs Bag, and received in an earthen Pan, or other Mould, which is to be firſt rub'd over with a little Honey.

When all the Wax is run through, this is to be ſet to cool very gently in a tolerably warm Room, and when thoroughly cold, and taken out, the Bottom is to be pared off, and it is ready to be ſold.

This is the plain and uſeful Way of managing Bees, and making the moſt of their Produce. A great many very ingenious Contrivances have been made for the Curioſity of Perſons of Speculation; but nothing more than this need be regarded in Practice, when the Profit and Advantage are the Objects of the Attention.

End of the FIFTH BOOK.

A COMPLEAT BODY OF HUSBANDRY.

BOOK VI.

Of TILLAGE. In SIX PARTS.

I. *Of Plants, and their Nouriſhment.*

CHAP.

1. *Of the Roots of Plants; their Kinds and Forms.*
2. *Of the Extent of Roots.*
3. *Of the Manner of Roots receiving their Nouriſhment.*
4. *Of the Importance and Uſe of the Leaves of Plants.*
5. *Of Accidents ariſing from the Loſs of Leaves.*
6. *Of the Nouriſhment of Plants.*
7. *Reaſons for ſuppoſing the Nouriſhment of all Plants the ſame.*
8. *The Objections againſt the Nouriſhment of all Plants being the ſame, conſider'd.*
9. *Reaſons for it deduced from the Practice of Huſbandry.*
10. *The Reſult of Experiments on Vegetation.*
11. *Of the changing of Crops.*
12. *Of the Diſtribution of the Nouriſhment of Plants in the Earth.*

II. *Of the Advantages of Tillage.*

13. *Of the ſeveral Methods of dividing the Particles of the Earth.*
14. *Of the Degrees of Tillage, and of the Uſe of Dung.*
15. *Of the joint Advantages of Manure and Tillage.*
16. *Of the Preparation of Wood Land for Corn.*
17. *Of the Preparation of heathy Land for Corn.*
18. *Of the Preparation of Land for Corn after the artificial Graſſes.*
19. *Of the Preparation of Land for Corn after common Graſs.*
20. *Of keeping Land in Heart by Tillage.*
21. *Of the Nature of the Improvement by Tillage.*

III. *Of the Implements of Huſbandry, and their ſeveral Uſes.*

CHAP.

The INTRODUCTION.

Of Improvements in Husbandry, and the Manner to undertake them.

WE now enter upon the greatest Article within the Compass of the Farmer's Business: a Subject of the utmost Concernment and Importance to the Publick, as well as to his private Consideration; and though the most continually practised of any, the least understood of all.

We have throughout this Work endeavoured to acquaint our Husbandman with the Reasons of his several Practices, and shall more particularly than on any other Occasion, attempt it here; because there is no Part in which Improvements are more wanted, nor any in which they are so easily made: while at the same Time they are in this Article of much greater, and more general Advantage than in any other.

There is but one Way of rationally setting about Improvements in Husbandry: this is by understanding as well as by observing the Practice of others, and applying what may be discover'd from such reasonable Experience, to other and farther Parts of the Subject.

It is for this Reason we have hitherto been careful to explain the Nature of the several Operations we have described, that they might serve not only as Guides by which to work, but as Principles whereon to reason: and it is by this Method, and this only, we shall endeavour to enlarge the Knowledge of the Farmer on this most important Head; that he may know in what Manner to undertake whatever Reason and the Consequences of others Experience, shall shew him to be practicable, at the same Time that it points out the certain Utility and Advantage of it when atchieved.

We have in the five preceeding Books instructed him in the preparing, planting and stocking his Farm; omiting, as we hope, no useful Knowledge on those Subjects: he is therefore now prepared to enter upon the Tillage of his Land; and, according to the general Information conveyed under the preceeding Heads, he is to consider by what Method that may be set about to his best Advantage.

The old Practices of Husbandry had their Use, for every Kind of Tillage adds to the natural Fertility of the Ground; but in the Course of an Employment followed by so many Persons, in so many Places, and for so long a Period of Time, it is not to be doubted but Improvements must have been made. To resolve to adhere only to the old Methods, were to shut the Door against Knowledge; and to admit all that have been proposed among the new, were to perplex instead of informing ourselves by Experience.

All Sciences are rude and imperfect at first, and they by Degrees refine and arrive at more Perfection. The greatest Advances are made in them by frequent Practice; and none admits so continual Experience as this. Among the many who follow it, the far greater Part think no farther than to imitate the Labours of their Fathers: and of those who have had the Spirit to pursue the Subject farther, too great a Part have been carried away by Fancy, and have laboured rather to establish some new System, than to add to real Knowledge. These are to be little regarded: but, on the other hand, too much Respect cannot be shewn to those who have followed Utility in their Studies, and adhered to Truth in the delivering the Result of them to the Publick. 'Tis from these we are to hope for real Improvements in this Art; and we shall find in their Writings the best Foundation on which to build our reasonable Attempts for the carrying Agriculture to a greater Perfection.

Among the Writers who may be useful in furnishing Instructions for the Improvement of this Art, there is not one who deserves greater Praise than Mr. TULL, the Author of the famous Treatise on Horsehoeing Husbandry. This Gentleman has not only been of Service, but has done Honour to his Country, for the greatest

Respect

Reſpect has been ſhewn to his Writings, by thoſe who cultivate uſeful Studies in every Part of EUROPE. The Method he has propoſed, has in it a great deal that is new, and in the higheſt Degree uſeful; but there are Faults as well as Excellencies in his Book, and while we give it the due Praiſe, we are to caution the Reader againſt too cloſe an Adherence to all its Propoſitions.

This Author had a great deal of Experience, the true and rational Source of all Knowledge on this Subject; and he had directed his Purſuits upon a new Plan. He has furniſh'd innumerable Hints for Improvements, and has carried many of them himſelf to a great Degree of Perfection: but he is too fond of the Syſtem he wrote to eſtabliſh; and the new and uſeful Diſcoveries with which his Treatiſe abounds, are clouded by vague Reaſonings, and often buried in a tedious Prolixity. This impartial Account we have thought it neceſſary to give of ſo late, and ſo conſiderable an Author, to whom we ſhall be obliged for a great deal of uſeful Knowledge on the Subject which we are to treat in the preſent Part of the Work: whoſe uſeful Diſcoveries we intend to preſent to the Reader, without his Errors or his Partiality; as they have been approved or condemn'd by thoſe Foreigners who have adopted the Practice, and as they ſtand confirmed or contradicted by Experience.

It is to this ingenious Writer that we owe the Eſtabliſhment of Horſehoeing Huſbandry practiſed in ſome Parts of ENGLAND at this Time, and with great Succeſs in many other Countries. We ſhall treat this Improvement in the Cultivation of Land carefully, as it contains more real Matter of Uſe than any other which has been made: but in our Obſervations on this Head, we ſhall form the Advice we ſhall give to the practical Huſbandman, not upon this or any one Author alone, but upon the Reſult of their ſeveral Opinions, and of the Experience of thoſe who have brought their Propoſals, in whatever Branch, to Trial.

Mr. DU HAMEL in his Treatiſe on Cultivation, has adopted what was uſeful in Mr. TULL; adding what he had farther diſcovered, and retrenching his Errors: what he did by Mr. TULL we ſhall do by him. It is thus the Writings of one Author are made uſeful by the Labours of another.

The Horſehoeing Huſbandry to be deſcribed in the ſucceeding Chapters, ſeems to have owed its Origin to a long neglected Paſſage quoted by Mr. EVELYN. The moſt celebrated Authors we find are not the moſt read; the Paſſage is this, "Take ſome of the moſt barren Earth you can find, powder it well, and expoſe it abroad for a Year, ſtirring it about frequently: it will become ſo fertile as to receive and nouriſh a Plant from the INDIES, and will cauſe all Herbs to proſper in the moſt exalted Degree, and foreign ones to bear their Fruit as kindly as in their natural Climates."

If we add to this remarkable Quotation the Contrivance for ſowing, invented by LUCATELLO, an ITALIAN, and publiſhed in the ſixtieth Number of our Philoſophical Tranſactions, which in the eſſential Points agrees perfectly with that propoſed by Mr. TULL; we ſhall find that the Foundation of Horſehoeing Huſbandry has been long ſince laid, and ſhall wonder that what had been ſo plainly delivered in Books, was not before brought to Practice.

The Uſe that has been made of theſe Diſcoveries and Inventions ſince, and the Improvements that are now carrying on in many Parts of EUROPE, by the Practice of Horſehoeing Huſbandry, ſhew the great Utility of Books in proper Hands: nor does the Inventor or the Writer deſerve more Praiſe, than the Perſon who brings what they have deviſed into real Practice.

In our Conſideration of the Tillage of Land, we ſhall fully explain the great Improvement of Horſehoeing Huſbandry, taking that lateſt invented Method firſt into Conſideration, as there will be Opportunities of explaining the Nature of Tillage more from it, than from any other; and as in order to the entering into the Advantages of this, or any other Method of Huſbandry properly, there ſhould be firſt conveyed ſome general Knowledge of the Nature of Cultivation, and of the Benefit the Earth receives from it in the affording Nouriſhment to Plants; we ſhall premiſe ſome general and particular Obſervations on this intereſting Head. For the better underſtanding of theſe, we ſhall begin with explaining to the Reader, who is not accuſtomed to theſe Reſearches, the Nature of the Vegetables themſelves.

In order to underſtand in what Manner Nouriſhment may be conveyed to the Roots of Plants, he ſhould firſt be acquainted with the Nature of thoſe Roots which are to receive it. For this Reaſon we ſhall follow the Method of thoſe who have written moſt rationally on this Subject, and premiſe to our Obſervations on the Manner of cultivating Land; ſome Remarks upon the Nature and Texture of the ſeveral Parts of Plants as they regard the preſent Enquiry; conſidering them only ſo far as their Knowledge may be uſeful to the Huſbandman.

BOOK

BOOK VI. PART I.

Of the Parts of Plants, and their Nouriſhment.

CHAP. I.

Of the Roots of Plants, their Kinds and Forms.

WE are about to explain the Effects of Tillage; and we ſhall, in order to this, firſt give ſome Account of the Parts of Plants, and of the Manner in which they are nouriſhed. Roots, ſo far as the Huſbandman is concerned in their Conſideration, may be divided into two Kinds: firſt, thoſe which ſpread under the Surface of the Ground, and ſecondly, thoſe which penetrate ſtrait down: the firſt of theſe we ſhall call ſpreading Roots, and the other tap Roots, and there will need here no farther Diſtinction.

The tap Roots plunge perpendicularly into the Earth, the others, according to their Name, diſperſe themſelves every Way, at a ſmall Diſtance under the Surface.

Thoſe Roots which firſt ſhoot from the Seed of a Plant, are always of the perpendicular Kind: they plunge themſelves ſtrait down into the Earth, and continue piercing deeper and deeper, till they find it too hard for their proceeding farther. In Places where the Soil is ſoft and deep, theſe Roots penetrate much farther down than is imagin'd. They will reach many Yards into the Earth, if uninterrupted and uninjur'd.

When theſe Roots are hurt or cut, whether by Accident or Deſign, they change their Nature, and each divides into many others. This is an Obſervation not eaſily made in its full Extent, in Plants growing in the Earth, becauſe they cannot be taken up perfect; but Experiments made on ſuch as are rais'd in clear Water, ſet it in a very ſtrong Light. Such Trials have been made by the FRENCH in great Numbers; they may be repeated and enlarged with Eaſe; and will not fail to let a great deal of new Light into the Doctrine of Roots.

All tap Roots puſh out certain Branches, or Fibres, which ſpread in an horizontal Direction: and theſe Branches are the more vigorous, the leſs they are buried in the Earth. The moſt ſtrong and ſerviceable therefore ſpread always near the Surface of the Ground; and within that Depth of the Soil which is mov'd by the Plow and other Inſtruments of Huſbandry.

Theſe are of the Nature of thoſe Roots which we call horizontal. Some Plants have, in this Manner, a main Body which runs ſtrait down, and Fibres growing from it: others conſiſt of theſe ſpreading Fibres only, they run often to a very great Diſtance from the Plant; but in this Caſe they become ſo ſmall that they are hardly to be diſcovered; eſpecially when they are of the Colour of the Earth among which they lie, as theſe very ſmall Fibres commonly are.

A Carrot appears to the incurious Obſerver to have only one Root, which is long, thick, and perpendicular, with a few ſhort Fibres about it; yet it is found, on a more ſtrict Examination, to ſpread a great Number of very fine and ſmall Fibres to a great Diſtance every Way. Theſe are its horizontal Roots; they are of the ſame Colour with the Earth among which they run, and therefore they are not to be diſtinguiſhed but by a very ſtrict Examination.

This is the Caſe with other Plants, as well as the Carrot, and nothing is eaſier than to be convinc'd of it by an Experiment which Mr. TULL propoſes. Let a Piece of new and firm Earth be dug in Form of a long and narrow Triangle. Let the Length of this Piece of Ground be twenty Yards, its Breadth, at the Bottom of the Triangle, twelve Feet, and at the Top let it terminate in a Point. In this Piece of Ground let there be twenty Turnips rais'd from Seed, and let the Ground be kept well hoed. Now when theſe Roots are grown, if the Turnip that ſtands firſt, or in the narroweſt Part, at the Top of the Piece, be as large as that which ſtands at the Bottom, in the Middle of the broadeſt Part, it will be a Proof that the horizontal Fibres ſent out by theſe Roots, ſpread very little in ſearch of Nouriſhment; for they cannot eaſily go beyond the Part that is dug. If the Turnips be gradually larger and larger from the Top, or narrow Part, to the Bottom, it will ſhew that a Turnip ſends out ſmall Fibres to a great Diſtance in ſearch of Nouriſhment, and that it grows in proportion to the Diſtance they extend. Thus would ſhew that a Turnip ſends out Fibres, to at leaſt ſix Foot diſtance every Way, for there is nothing elſe to make the laſt Root bigger than the others; and twelve Foot is there the whole Width of the Ground that is dug. But if the firſt Root, that is, that which grows in the narroweſt Part be ſmall, and thoſe Roots which follow it in a Line to the broader Parts, grow gradually larger till about the Middle, and from thence to the broadeſt Part, continue much the ſame in Size and Vigour; then it will be found that a Turnip ſpreads its Roots three or four Foot every Way, according to the Breadth of the Piece of Ground where they have their full Bigneſs: and that it ſends them no farther.

The Roots do not penetrate, at leaſt not in any conſiderable Manner, into the hard Ground at the Edges of this Piece, where it has not been dug. This Experiment therefore, ſuppoſing this the Event, would ſhew the great Uſe of digging, hoeing, or plowing about theſe Roots, for furniſhing them with Nouriſhment: and it would

ſhew, that be the Earth ever ſo well prepar'd, it is of no Uſe to them at a greater Diſtance than three or four Foot every Way; therefore we ſhould ſee by this, how much Space is uſeful to be left about a Turnip.

This Experiment may be extended to other Roots as well as Turnips, indeed to all other Plants whatſoever; and it will ſhew, ſufficiently for all uſeful Purpoſes, to what Diſtance they ſeverally ſpread their Fibres, and how far the Earth is to be cultivated and left vacant for their Service; on this depends the great Advantage of Horſehoeing Huſbandry, as will be ſeen in a ſucceeding Section.

CHAP. II.

Of the Extent of the Roots of Trees.

MR. Tull obſerves, that the Roots of the white Thorn Shrubs in an Hedge, which has a Ditch before it in the uſual Way, penetrate below the Bottom of the Ditch, run under it, and riſe again on the other Side, to the richer Soil which lies near the Surface, eſpecially if it have been wrought; and then ſpread horizontally for more Nouriſhment.

The ſame Obſervation has been made by Mr. Du Hamel, with Reſpect to a Row of Trees, which ſeem'd to be kill'd by a deep Ditch that was dug at a little Diſtance from them, in order to prevent their Roots from ſpreading into the neighbouring Ground; but theſe Trees, in a little Time, ſent down their Fibres below the Bottom of the Ditch, which, when they had paſs'd, they roſe again toward the Surface, and ſpread themſelves through the Soil that was wrought, to a great Diſtance every Way. The Trees had faded at firſt, upon the digging of the Ditch, but as ſoon as their new Roots had got into the good Ground, on the other Side, they recover'd.

If a Ditch be dug lengthwiſe, at a ſmall Diſtance from a young Tree, and fill'd up with good Earth, the Roots of the Tree will ſoon get into it, and will follow the Direction of the Ditch, extending themſelves in the good Earth that fills it to a great Length.

In the ſame Manner when Trees are planted too deep in the Earth, they languiſh till they have ſent up their Roots into the upper Part of the Ground, where it is ſtir'd by Culture; but as ſoon as they have got there they revive and flouriſh. The Folly of planting Trees too deep, appears very plainly from this Obſervation; and when that Fault has been committed, and a Tree is ſeen to ſuffer by it, the beſt Method is to take it up and plant it again ſhallower.

I have obſerved that of late Years the young Trees planted about London ſucceed worſe than formerly, a good Part of them dying altogether, and others loſing their Tops: upon examining into the Reaſon, I have generally found it to be the planting them too deep. One would ſuppoſe all the Arts ſhould be beſt underſtood near the Metropolis, but that of planting is not: this Hint may perhaps be uſeful.

Theſe and many other Obſervations which might be cited, prove that the Roots of Trees ſpread to a great Diſtance, when they get into Ground that has been ſtir'd, and that they will run a great Way, and take ſtrange Courſes to find it. The Roots of all Plants, Corn and Graſſes, do the ſame. Leaves are the Organs of Tranſpiration in Plants, Roots are thoſe deſtin'd for attracting and drawing the Nouriſhment. It is evident that, in order to the Growth of a Plant, more Sap muſt be taken in than is tranſpir'd; and as all Plants encreaſe in Growth, it is plain this is done. If we look upon the great Extent of Surface in the Leaves of Vegetables, the Organs of Tranſpiration, we cannot doubt but that the Fibres of their Roots, which are the Organs of Suction, muſt be extended in a like Manner. Reaſon ſhews that it ought to be ſo, and late Obſervations and Experiments ſhew that it is. It has been aſſerted that they run out in Length as much as the Leaves expand in Surface, although they are not ſo obvious to the Eye.

But ſome Reſtriction is to be obſerved in this Aſſertion. Plants tranſpire only in the Day: on the contrary, during the Night, they revive and imbibe the Dews and Rains, and what they thus receive contributes greatly to their Growth and Encreaſe. We are to add alſo, that there is no Proof that either the Tranſpiration or Suction in Plants are proportioned to the Surfaces of the Parts; and for ought that is hitherto known, an Inch of Root may imbibe a larger Quantity, than an Inch of Leaf tranſpires.

But, however this may be, it is certain that the Roots of Plants extend to a great Length, much beyond what has heretofore been imagined.

CHAP. III.

Of the Manner wherein the Roots of Plants imbibe their Nouriſhment.

IN the ſame Manner as the Lacteal Veſſels in an Animal have their Openings in the Inteſtines, for taking in the Chyle, the Roots of Plants have their Openings in their Lacteals, or more properly in their Sap Veſſels, on their Surfaces. But there is yet a great Difference, Animals can go about to ſeek their Food and fill their Stomachs and Inteſtines, while Plants are obliged to ſpread their Roots in the Soil, where they ſtand to imbibe their Nouriſhment. It is neceſſary, for this Reaſon, that their Roots ſhould extend to a conſiderable Diſtance, otherwiſe they would quickly exhauſt the Earth that lies juſt about them.

We may carry this Compariſon ſomething farther: we obſerve that the Preſſure of the digeſted Food againſt the inner Surface of the Inteſtines, contributes, together with the periſtaltick Motion of thoſe Parts, to the Introduction of the Chyle, or nouriſhing Juice of Animals, into the Lacteals: and in the ſame Manner the Efforts which theſe ſmall Roots of Plants make in extending themſelves among the ſmall Particles of fine Earth, the Preſſure of the wrought

Earth againſt the Roots, and the Re-action of the Roots againſt the Earth, as they encreaſe in Bigneſs, and as that cloſes after the breaking by Culture, anſwers, in ſome Degree, to thoſe Motions in the Inteſtines, ariſing from their Reſiſtance and their periſtaltick Undulation.

To this, which is an Obſervation of Mr. Du HAMEL, we may add another great Article in the Proceſs of the Roots of Plants obtaining their Nouriſhment; which is the Effect of Heat. There is Heat in all Things in the Roots which are to receive Nouriſhment, and in the Earth which is to give it: and this Heat differs in Degree almoſt every Moment, as is ſeen by Experiments. Things expand with Heat, and they contract with Cold: therefore they are expanding and contracting, more or leſs, every Moment. This gives Motion and Preſſure between the Roots and the ſmall Particles of Earth continually, and this will much better than any other Means ſhew the Analogy there is between the Nouriſhment of Plants and Animals.

This is indeed the true Source of the Nouriſhment and Growth of Vegetables; and all that has been diſcovered by Mr. TULL, and thoſe who have followed his Train of Reaſons, joins to confirm it. Heat is the Cauſe of all Motion, and is doubtleſs the immediate Agent in the Hand of the Creator, for the keeping the whole Frame of Things in Order.

What has been obſerved of the Action of the Particles of Earth upon the Roots of Plants, ſhews, in the ſtrongeſt Light, the Uſe of ſtiring and breaking the Ground by Culture, that the Roots may the more eaſily make their Way through it, and that it may preſs them as it cloſes after the breaking.

Whatever be the Reaſon, Experience ſhews that Roots of Plants are always in the beſt Condition for obtaining Nouriſhment, where the Soil in which they run is light and fine. If two young Trees be pulled up, the one of which has grown in a light, and the other in a heavy and hard Soil, we ſhall find, on Examination, that the Tree which had grown in the heavy Soil, has but a ſmall Number of Roots, and thoſe large and ſtrong; whereas that which has grown in a light Soil has a vaſt Multitude of Roots, and all ſmall and fine: and to purſue this Subject farther, let a Tree be rais'd in pure Water alone, where there is no Reſiſtance at all againſt the ſpreading of the Roots, and we ſhall perceive that they are all nothing more than the ſlendereſt Filaments.

The Culture of a Soil therefore plainly occaſions the Roots of whatever is ſown in it, to be much more numerous, and finer, than they otherwiſe would have been; and Experience ſhews alſo, that it is not from the large and thick Roots, but from theſe ſmall and fine ones, that Plants receive their principal Nouriſhment.

It has been ſaid, in a preceeding Chapter, that when a Root is cut it alters its Courſe and Direction. This is to be explained farther, and it gives the greateſt of all Proofs, of the Benefit Plants receive from the digging about them. When a Root of a Plant is cut off, it does not extend any farther immediately, and in its Form, or Courſe in Length; but it ſends out a great Number of ſmall and fine Fibres. Here are therefore, from the cut Root, a Number of others produced, which are of the proper Kind for drawing Nouriſhment, and the Ground is at the ſame Time made ready to receive them, when this is done in digging about the Plant. When the Huſbandman digs, or any other way divides the Ground near his Plants, he cuts or breaks off a great many of their Roots: and inſtead of hurting them by this, we ſee from every one ſo broken, there grow a great Number of others more uſeful than the firſt.

CHAP. IV.

Of the Importance and Uſe of the Leaves of Plants.

LEAVES, we have obſerved already, are in Plants, the Organs of Tranſpiration, theſe are ſo neceſſary to the greateſt Part of Vegetables, that they cannot ſubſiſt without them. If we pull off all the Leaves of a flouriſhing Tree, it will commonly die. This indeed is not always the Conſequence of ſuch Loſs; for we ſee Trees ſometimes entirely rob'd of their Leaves by the devouring Caterpillars, and they recover: but that is done gradually, and moſt Trees will die if ſtrip'd at once. The Effect however may depend alſo on the Circumſtance. In ſome Conditions a Tree may be able to bear the Loſs of all its Leaves, and in others not.

GREW has ſhewn, that the Leaves of a Tree which are to burſt forth in Spring, are formed in the Buds the preceding Autumn: they are at that Time very ſmall, but they are proportioned to their Uſe.

Beſide theſe, which may be called the autumnal Leaves, there is a Reſerve in Plants for others: for when Mulberry-trees have been ſtrip'd of their Leaves to feed Silk Worms, in the Beginning of Summer; or when other Trees have been render'd naked by Inſects, there grow another Quantity in the Place. This is a Proviſion of Nature in Favour of Trees and Plants, that they may not always periſh by the Loſs of ſo abſolutely neceſſary Parts.

GREW diſcover'd, in examining the Leaves of Plants, that beſide the Network of longitudinal Fibres, which form the Courſe of the Leaf, there are a Number of Veſicles fill'd with Air. From this Obſervation many have concluded, that the Leaves were the Lungs of Plants; that they receiv'd the Air from the Atmoſphere; that this Air made its Way through the Plant down to its Roots; and that it there produced an Effect upon the Sap receiv'd from the Earth, of the ſame Kind with that it occaſions in the Blood of Animals.

Mr. PAPIN has alſo publiſhed a great Number of Experiments, which ſeem to favour this Doctrine; he ſays, That on putting a whole Plant into the Receiver of an Air Pump, it periſhes immediately, on exhauſting the Air; but that if the Roots alone be immers'd in the Receiver, and the Stalks and Leaves remain in the Air, which may be eaſily contrived by letting them out, and ſecuring the Opening with Wax, the

Plant

Plant will remain alive a long Time. This was propoſed by the Author, and has been received by the Publick as a Proof of the Reſpiration of Plants, and that their Leaves are the Organs.

The many Experiments made by Dr. WOODWARD, Mr. MARIOTTE, and Dr. HALES, prove abundantly that the Leaves are Organs of Tranſpiration, and that the greateſt Part of the Sap imbibed by the Roots, eſcapes through them. Indeed if we compare the Quantity of Sap that is taken in by the Roots and other Organs, with the Quantity that is let off by Tranſpiration, we find that the Remainder is what is left in the Subſtance of the Plant, and that if there be any other Account in the Sap, it is inconſiderable.

We know alſo that the Leaves of Plants do imbibe the Moiſture of Rains and Dews, and that this is very beneficial to the Growth. This is a plain Uſe of the Leaves; but we may extend their Benefit a little farther.

It is ſaid that the nutritive Juice receiving a certain Preparation in the Leaves, is thence diſtributed throughout the whole Plant for its Nouriſhment: but this ſuppoſes the Circulation of the Sap in Plants, which is a Thing not proved by any Experiments: indeed it is a Fact very much to be doubted, not only becauſe it has been advanced without Proof, but becauſe there do not appear to be two Kinds of Veſſels in Plants, as Veins and Arteries in Animals; the one of which ſhould carry up the Sap, and the other bring it down again. All that there ſeems to be in the Motion of the Sap of Plants, is a Kind of tremulous and uncertain Undulation, owing to the different Temperature of the Air.

Thoſe who argue for the Circulation of the Sap, ſay, That according to the other Doctrine, it muſt be ſuppoſed to be prepared by Degrees as it riſes in the Plant; and that there is not any Experiment or Fact to prove, that it is in any greater Degree of Perfection in the upper than in the lower Parts of it. And it muſt be allowed ſurprizing, that the Sap received into the Roots of Plants, ſhould be at once ſo perfectly prepared as to ſerve all the Purpoſes of Vegetation, and be able to ſupply with proper Nouriſhment the ſeveral Parts of the Vegetable. Upon this Plan of Reaſoning, and theſe Objections to the other Doctrine, the Aſſerters of a Circulation of Sap ſay, that it is altogether neceſſary for explaining Vegetation, to allow that it paſſes through the Leaves, returns thence through the Body of the Plant, and afterwards goes to the Leaves again; as the Blood in Animals returns to the Lungs, after having gone through every Part of the Body. This is a very ſpecious Reaſoning, but there wants Experiment to confirm it; and, on the contrary, innumerable Facts ſtand directly againſt it.

The Reader ſees what is advanced on both Sides, and the Reaſons; but he will find the Tranſpiration of the Leaves all that is proved with Certainty.

Whatſoever be the particular Office of the Leaves of Plants, Experiments ſufficiently ſhew, that they are of Benefit, and even of the greateſt Uſe and Neceſſity to the whole; this is the Huſbandman's material Conſideration.

If one cut off half, or two thirds of the Leaves of a young Tree that is full of Sap: we ſhall find that it will loſe its Sap in three or four Days after. The Bark which before would eaſily ſeparate from the Wood, will then ſtick firmly to it; and it will be impoſſible upon the very Day after the Cutting off the Leaves, to perform many of thoſe Operations in Gardening upon it, which might have been done while the Leaves were there. The Difference therefore made by taking away the Leaves only in part, is very evident to the Senſes.

A Willow, a Poplar, or any other Tree, but particularly thoſe of the ſoft Wood Kinds, will grow and flouriſh for a great many Years, and continue with a ſound Trunk, provided it be left to the Courſe of Nature, and permitted to keep its Head and its Branches; but, on the other hand, when one of theſe Trees has the Head cut off for ſhrowding, the Trunk quickly decays and grows hollow. This is moſt frequently owing to the Wet that gets in at the Parts where the Head at firſt, or the Shrowds afterwards are cut off; but if ever ſo much Care be taken in the Shrowding, the Tree does not continue ſound as it would have done in its natural State. No Pollard Tree ever continuing firm and good in the Trunk, any proportionable Time to the ſame Kind of Tree left with its Head and top Branches. The Heads and high Branches of Trees are what carry the great Quantity of the Leaves; it is therefore plain from this Circumſtance, that the Leaves of Trees preſerve the very Trunk in Soundneſs.

On the ſame Principle it is, that the Injuries of the Leaves of Corn affect the Ear. We ſee as ſoon as ever they are attacked by any Diſorder, the whole Plant declines. This is a Proof like the former, that the Leaves are a Part of the utmoſt Importance to Plants of all Kinds, and that the healthful State of the whole depends entirely upon them. Not only the whole Plant ſuffers when they are taken off, but when they are only diſeaſed.

From all this it appears, that the Leaves of Plants, in whatſoever Senſe we conſider them, are of the utmoſt Importance to the whole: and as the Leaves are thus important, ſo are the ſmall Branches that ſupport them. It is for this Reaſon that Cutting, eſpecially if it be done too cloſe, is certain Deſtruction to the FRENCH Furze, and many other Shrubs; and to the ſame Principle is to be referred the vaſt Damage that is done to the Saintfoine, Lucerne, and Clovers, when they are permitted to be eat down too cloſely by Cattle; and eſpecially while they are young. The Injury is of the ſame Nature with that done to Trees by ſhrowding: they ſuffer by it extreamly while tender, though when their Roots are well formed, and have ſpread far into the Ground, they recover it.

It is a common Cuſtom among our Huſbandmen, to turn in their Sheep upon their Corn Fields, when the young Blade is too rank: we ſhall in a ſucceeding Part of this Work, adviſe ſome Reſtrictions and Limitations to this Practice; and they will be founded on this Principle, of the great and neceſſary Uſe of the Leaves

to all Plants, and the Injury of cutting, or takeing them off.

From theſe Conſiderations of the principal Parts of Plants with Reſpect to their Growth and Nouriſhment, the judicious Huſbandman will naturally be led to the Reaſons of thoſe Effects he ſees ariſe from Culture: and underſtanding what he ſees, he will be able rationally to advance farther. We ſee here that the Roots of Plants differ in their Forms, and we ſhall find upon farther Examination, that they alſo differ in their principal Uſes. The tap Roots which penetrate deep into the Body of the Ground, ſerve to keep the Tree or Plant firm in its Place, and thoſe which ſpread horizontally in the upper Coat of the Earth, that is, the Soil, which is the Seat of Culture, ſupply it with Nouriſhment. One Kind therefore may be moſt needful to one Sort of Plants, and the other to another; though every Plant in ſome Degree requires, and has the Aſſiſtance of both. Nature has given them according to their ſeveral Occaſions, the Oak and the Walnut have vaſt tap Roots to ſecure them from the Violence of the Winds, which elſe taking ſuch hold againſt their ſpreading Tops, would tear them up out of the Ground; while humbler Plants have the horizontal Roots moſt conſiderable, for ſupplying their uſeful Products whether in Ear or whatever other Way with Nouriſhment.

Nature anſwers different Purpoſes by the ſame Means, and often employs theſe tap Roots to draw Nouriſhment; for they are common in many Plants which have no great Head, as Saintfoin and Lucerne, and ſeveral others that might be inſtanced; but in the general Courſe of Things, it is the other Uſe to which they principally ſerve. In the ſame Manner, the ſpreading Roots which are particularly deſtined to ſupply the Plant with Nouriſhment, aſſiſt alſo, and that very greatly in keeping it in its Place.

With Reſpect to theſe ſpreading Roots, it will be found on Examination, that they grow to the greater Length as they run nearer the Surface of the Ground, becauſe they are there moſt within the Reach of Rains and Dews, and moſt under the Influence of the Sun's Rays: they alſo extend farther and wider in Proportion to the Condition of the Ground, and always run fartheſt where the Soil is moſt broken by Culture: for 'tis plain from repeated Experience, that all theſe Roots run out in Length, and multiply, in Proportion to the Eaſe with which they make their Way: and they always puſh themſelves with the more Eaſe, the more the Ground has been broken and rendered ſoft by Culture.

As to Leaves, we find that they are of the utmoſt Importance to the Plant; and that on a double Account; as they diſcharge the Redundance of thoſe Juices that have been taken in by the Root, and as they contribute to its abſolute Increaſe alſo, by imbibing nouriſhing Matter from Rains and Dews themſelves. Theſe are two very different Offices to be performed by the ſame Organs, but we plainly perceive that it is thus Nature reciprocally uſes them. They diſcharge the Redundances by Day, and they inbibe Moiſture during the Night.

The Importance of the Leaves to the Plant is ſhewn abundantly by the Experiments and Facts that have been here mentioned; but whether any one of the Syſtems that have been propoſed be altogether true, at leaſt whether it contain the whole Truth, and explain the whole Uſe of thoſe Parts, is not yet determined. We have for this Reaſon delivered them all, that the Reader may ſee in one ſhort View, what has been advanced for either Syſtem by its ſeveral Advocates, and may for himſelf determine by what he ſhall ſee in Practice, which is moſt right; or how far either.

The whole has its Uſe in the Practice of Huſbandry. What has been laid down concerning Roots, is a Matter of immediate Concern in the Cultivation of every Kind of uſeful Growth whatſoever; and the Knowledge of this Importance of Leaves will be of no leſs Conſequence in the Conſideration of many of thoſe particular Vegetables the Cultivation of which will be delivered in our Seventh Book; and which not being ſo univerſally the Objects of the Farmer's Care as the common Kinds of Corn, are not ſo well underſtood with Reſpect even to the common Articles of their Management.

CHAP. VI.

Of the Nouriſhment of Plants.

NOTHING is more difficult than to ſay, what is the Nature of the nutritive Juice of Plants: no Queſtion has been more debated by Philoſophers, and none with leſs Succeſs. It would be natural to think that this might be diſcovered by the Nature of the ſeveral Subſtances we uſe as Manures; but in Reſpect of theſe, we ſee the Effect only: this is very plain and obvious, but nothing is more hidden or difficult to find than the Cauſe.

We have ſhewn in our Second Book what are the ſeveral Subſtances uſed as Manures, and from many of theſe one would be led to ſuppoſe, that the Sap which is ſo evidently increaſed and enriched by them, conſiſted of Salts and Oils, and other Things ſuch as Chymiſtry is able to extract from theſe ſeveral Ingredients: but then the Effects of many of the more ſimple Kinds of theſe Manures, which are often equal to thoſe of the moſt ſeemingly powerful, ſhew that this is not the Caſe: and we are the more confirmed in this, when we conſider that bare Sands will ſupport many Plants; and that many others may be raiſed in pure Water: and that in either Caſe they have the ſame Qualities and Virtues with thoſe of the ſame Kind raiſed in Earth, dreſſed with the richeſt Manures. This leads one to imagine, that the Sap, or abſolute Nouriſhment of Plants, is in itſelf a Thing much more ſimple than it would be natural otherwiſe to think; and that it obtains all this Variety of Taſtes, Smells and Qualities from the Organs of the Plant.

Mr. Tull is of Opinion, that the Nouriſhment, or as he expreſſes it, the Food of Plants, is nothing but the Particles of Earth reduced to

a very fine Powder. Others have had Recourſe to Salts as the great Article of the Nouriſhment of Plants; and many have called in Fire, Air, Water and Earth, to ſerve the ſame Purpoſe; ſome prefering one and ſome another, according to the Syſtems they choſe to favour. But this has all been found imaginary, from the Reſult of frequent Trials; and if we can ſuppoſe the Matter of pure Earth capable of being reduced to a State of Solution in Water, or but of being ſo broken and divided by it, as to be in a Condition to be received into the fineſt Veſſels of Plants, we ſhall adopt an Opinion much more agreeable to Reaſon, as well as to the common Courſe of Things, in ſuppoſing Earth itſelf thus reduced to exceedingly ſmall Particles, to be the very Matter of the Nouriſhment of every Thing that grows on it.

We find that all Vegetables are finally reduc'd to Earth by Corruption, and to what ſhould a Thing be reduced by this, but to that Subſtance of which it originally conſiſted. Probably the Manures we add for the Melioration of Earth, be they of what Kind they will, ſerve to no other Purpoſe but the preparing that Earth for entering theſe fine Veſſels; and the utmoſt Effect of them may be nothing more than rendering the Earths with which they are mixed, fit for that Purpoſe.

For Inſtance, all the rich Manures contain a Salt: now theſe Salts may have an Effect in dividing the Particles of Earth, and thus preparing them for affording nouriſhing Plants. Again, Water may ſoften theſe Particles thus rendered extreamly ſmall, and Air and Fire may put them in Motion. In this Light, Fire, Air and Water may aſſiſt in the Growth of Plants, but it is Earth that affords the ſubſtantial Part, or Matter of their Nouriſhment. The Plant may be killed by taking away the Effect of Fire, Air, or Water, but without Earth it could not have its very Subſtance; perhaps it cannot live without the others; but without this it cannot exiſt.

The mention of Salts, Fire, Air and Water on this Occaſion of the Nouriſhment of Plants, is unavoidable, becauſe all who have read at all upon the Subject, have been accuſtomed to hear of them as the Sources of Nouriſhment jointly or ſingly; but no Knowledge was ever conveyed upon ſuch Principles. They are neceſſary to be named becauſe they have Effects on Plants; but nothing is ſo idle as to ſuppoſe that they eſſentially feed and ſupport them. Water indeed, in the Condition we have it, will do this, but we know Water contains Earth; and it is unqueſtionably by this Earth that is in the Water, that Plants are nouriſhed which grow in it.

We do not mean by Earth, when we ſpeak of it as the Food and Nouriſhment of Plants, that ſimple elementary Subſtance which the Chymiſts mean by the ſame Word, underſtanding by it Earth diveſted of all other Principles: on the contrary, we can extract all thoſe Principles from Plants, and we mean no other Thing by Earth on this Occaſion, than ſuch as compoſes a fine Soil, ſuch as it is found on the Surface of Land, and is called Mould.

That this is natural to Plants is evident, becauſe it will not injure them, which all the other Things pretended to afford them Nouriſhment will. Too much Salt will prevent their Growth, too much Water will kill them, and too much Air and Heat will dry them up; but too large a Quantity of Earth never does them any Harm. Indeed they may be injured by being planted too deep, becauſe their Roots may be buried in ſuch a Manner, as to be out of the Reach of the Air, Rains and Dews, and of the Influence of the Sun's Rays; theſe being neceſſary to their Growth, although they do not afford them the real Nouriſhment.

That abſolute Earth is the Nouriſhment of Plants appears from this, that ſuch as naturally grow in the moſt diſtinct and diſtant Places, are capable of being ſupported by any Earth indifferently in either. Thyme will not grow in a Bog, becauſe Thyme does not love much wet, but the Earth of the Bog is not in Fault, for that will feed it, if diveſted of its abundant Water; and removed to another Place. Let a Parcel of the Earth of a Quagmire that bears nothing but Ruſhes, be dried by the Sun, and placed at the Top of a Hill, and Thyme will grow in it; and in the ſame Manner let the Earth dug from a Hill be buried in a Quagmire, and when it is well wetted, Ruſhes will grow in that. 'Tis not therefore the Earth that differs: that is capable to ſupport any Plant: 'tis only altered by the Quantity of Water. The Plants of AMERICA ſucceed very well in the Earth of ENGLAND, as we ſee every Day in our Stoves and Green-houſes. If they are from a hotter Climate, they muſt have a proportioned Degree of Heat given by Art, but the Earth does perfectly well. We have argued in this Chapter for Earth being the Food of Plants, and we ſee in theſe Inſtances, that good Earth will ſupport and nouriſh all Kinds of them; provided they have the neceſſary Degree of Heat and Moiſture: this ſeems very greatly to ſupport the Opinion.

People of Curioſity tell us, that Water, and even Air, are capable of being fixed and converted into Earth; and ſome have imagined this of Water particularly, from its ſo freely feeding of Plants: but that is owing to the Earth it contains, as mentioned already. In fine, if we can as at firſt ſaid, get over the Difficulty of Earths not being diſſoluble in Water, or can ſuppoſe that without Solution it is capable of being rendered ſo fine, that it may enter the fineſt Veſſels of Plants; there appears great Reaſon on the Side of this Opinion, that Earth of an extream Fineneſs is properly and truly the Food or Nouriſhment of them: underſtanding by this Term Earth, ſuch as we find it in the Soil.

The ſucceeding Diſcourſe on Tillage will ſhew the Neceſſity we have been under of entering thus far into the preſent Subject; for otherwiſe, much of the practical Part would have appeared ſtrange and ill-founded: but whether Earth be in Reality the Nouriſhment of Plants or not, is to the practical Huſbandman no important Matter. If we can upon theſe Principles lead him to a Method of giving greater Fertility to his Land, we ſhall not be uneaſy upon the Sub-

ject

ject of that Uncertainty which reigns, and always will reign in the Enquiries into the Myſteries of Nature: the Explanation of the Nouriſhment of Plants being one of the greateſt.

CHAP. VII.

Of the Reaſons there are for ſuppoſing the Nouriſhment of all Plants the ſame.

IN Conſequence of what has been delivered as moſt probable in the laſt Chapter concerning the Nouriſhment of Plants, a Queſtion will naturally ariſe, Whether we ſuppoſe that the different Sorts of Plants take in the ſame Food, or the ſame Matter for their Nouriſhment, whatſoever that be? This is indeed a very difficult Queſtion, but it is very neceſſary to be conſidered for the Uſe of the practical Huſbandman: for on the Anſwer depends his Knowledge how to act in the varying or continuing the ſame Crops upon the ſame Piece of Ground.

We imagine that the Nouriſhment taken in by all Plants is the ſame, for we ſuppoſe that Nouriſhment to be no other than Earth in very fine Particles carried into their Veſſels by Water. But as a great deal of the Huſbandman's Practice in his tilled Lands will depend upon the Certainty of this Point, we ſhall not attempt to force this Opinion upon him: but ſhall lay before him the Objections that have been made, or may be made by others againſt it, and propoſe at the ſame Time our Anſwers: when he has the whole before his Eye at once, he will be beſt able to determine, whether he ſhall adhere to our Opinion, or to that of others.

Mr. TULL is the Founder of this Opinion, that the Food or Nouriſhment of Plants, is Earth; and conſequently, that all Plants take in the ſame: the Generality of Writers have adopted a contrary Doctrine: they ſuppoſe that every Plant draws from the Earth for its Nouriſhment certain Juices that are proper for it, and no other, never taking in the Earth itſelf at all.

On this Principle is founded the Opinion ſo common among the Generality of Writers, that a Piece of Ground may be exhauſted for one Kind of Plant, and not for another; and on this Opinion is ſuppoſed to be founded the Cuſtom of the practical Huſbandman, of every Year changing his Crops; the Succeſs of which Practice is alſo urged in Favour of the Opinion. This is a very ſpecious Reaſoning.

Barley, ſay they, exhauſts the Ground much more than Oats, when it is to be ſown afterwards with Wheat. This is a Fact, and on this they found their Opinion, that the Juices taken for the Nouriſhment of Barley, are more like thoſe required by Wheat, than are the Juices drawn by Oats.

In the ſame Manner they add, When a Piece of Ground has been a long Time occupied by one Kind of Tree, if ſome more of the ſame Sort be planted in it, they will ſucceed very poorly; but if Trees of ſome other Kind be ſet, there will be Hopes of better Succeſs.

These Facts when we ſtate in their full Strength, allowing their Truth, ſeem at firſt Sight to argue againſt the nouriſhing Matter of all Plants being the ſame: but on the other hand, there are a Multitude of other Obſervations founded in the ſame Manner on Facts, to be produced, which ſtand as fairly for the Opinion we propoſe, of the Nouriſhment of all Plants being the ſame: and theſe which ſeem ſo ſtrong againſt it may be refuted.

The firſt is very fairly propoſed, and therefore may be diſtinctly and exactly anſwered. Barley does exhauſt the Ground, on which Wheat is afterwards to be ſowed, more than Oats, as is ſeen by the ſucceeding Crop. But the Fact is no more than this, that Barley exhauſts Ground more than Oats, in ſome Soil: there is nothing in the ſuppoſed Part. Wheat requires a great deal of Nouriſhment, and it therefore ſucceeds beſt after Oats, not becauſe the Nouriſhment drawn by Barley was of the ſame Nature that Wheat required, or that drawn by Oats different; but becauſe the Barley had drawn in more Nouriſhment, and therefore had left leſs in the Ground. The Fact is plain, for we know Barley requires more Nouriſhment than Oats, for Oats will grow on poorer Land: and this is the whole Matter. The Fact propoſed is true, but the Cauſe miſtaken.

The other Objection, if it were ſtated more particularly, would be as eaſily anſwered. Oats requiring little Nouriſhment, will ſucceed after Crops that require more; and that when ſuch Crops would not: in the ſame Manner ſome Trees require more, and ſome will thrive with leſs Nouriſhment. When one Kind of Tree that requires a great deal of Nouriſhment has exhauſted a Piece of Ground, a freſh Quantity of the ſame Trees planted on it will not thrive, becauſe the former had exhauſted it: nor would any other Kind of Trees ſucceed, that ſhould require alſo a great deal of Nouriſhment. But if a new Kind of Trees be planted there which require leſs Nouriſhment, they will ſucceed, becauſe though there be but little, it may be ſufficient for them as they require but little.

A great Part of the Objections which are propoſed againſt uſeful Diſcoveries, might be anſwered by more ſtrict Enquiries in this Manner; they have had their Riſe in Error, and they have their appearing Weight only becauſe they are ſtated imperfectly. To ſee the whole of the Subject is to be ſatisfied that they ſignify nothing.

CHAP. VIII.

Other Objections to the Nouriſhment of all Plants, being the ſame anſwered.

THE firſt and principal Difficulty they raiſe who ſuppoſe every Plant to draw a peculiar Juice for its Nouriſhment out of the Earth is, that it does not appear probable the ſame Matter, and that alike in all Reſpects, ſhould be able to ſupport and give Increaſe to ſuch a vaſt Variety of Plants as we ſee, and thoſe ſo different in the moſt eſſential Points from one another; in their Forms, Taſtes and Virtues.

This,

This, like the reſt, has a ſpecious Appearance: but let it be conſidered notwithſtanding, fairly. There is no Doubt but that the ſmall Particles of Earth which we ſuppoſe to be the Nouriſhment of Vegetables, aſſume different Forms in different Plants; but this is no Proof that the nouriſhing Matter may not be altogether the ſame in the Earth, though altered in their Veſſels.

Experience alſo joins to ſhew, that the Nouriſhment is the ſame for all Plants, from what is ſeen in their Growth among one another. If a Lettice, for Inſtance, draws from the Earth a particular Juice for its Nouriſhment; and that Juice be different from what is drawn by a Plant of Succory, then it will follow that a Lettice ſet among Succory Plants, muſt flouriſh better than when ſet among other Lettices; nay, it ought in this Caſe, if the Doctrine of different Juices for every Plant were true, to flouriſh as well as if no other Plant at all were near it: but let this be tried, and the Reſult will be quite otherwiſe. A Lettice planted among Succory will flouriſh juſt as much as if it ſtood among other Lettices; not at all more; and it will not grow nearly ſo faſt, as if no Plant were by it. This ſhews that the Nouriſhment of Lettice and Succory are the ſame, and that Plants of any Kind exhauſt the Ground, and rob thoſe which are near them of Nouriſhment, as much if they be of different Species, as if of the ſame.

That the Nouriſhment of Plants, whatſoever it be, undergoes in their Veſſels that Change which gives it the particular Taſte, Colour, and Form which belong to the Plant, is evident from the common Effects of grafting Trees in Gardening. There is an Inſtance of Mr. DU HAMEL's, in the Memoirs of the FRENCH Academy, which proves this abundantly, and in a very particular Manner. A young Citron of the Bigneſs of a Pea, was let in by the Stalk to a Branch of an Orange Tree. The Citron grew to its full Bigneſs, and became perfectly ripe, it but was to all Intents and Purpoſes a Citron; having nothing of the Orange at all in its Nature, Form, Taſte, or Appearance.

Now if the Nouriſhment received by the Orange Tree could be thus prepared in the Veſſels of the Citron Stalk, and Fruit, what Reaſon can there be to doubt, but that the ſame Nouriſhment taken up from the Earth, may be wrought in every Plant into the Colours, Qualities and Forms that are peculiar to that Plant.

Many contend not only that there is a particular Juice taken out of the Earth by each Plant for its Nouriſhment, but that every Plant has more Kinds than one. The Pulp of a Peach, the Stone, and the Kernel, they obſerve are very different Things, and they ſay there ought to be three different Juices taken up out of the Earth to nouriſh them.

This is betraying their Cauſe by ſaying too much. Doubtleſs the Organs and Veſſels of Plants give the different Taſte and Smell to the Sap, as well as occaſion its various other Effects in the different Parts. We do not find in the Earth the Taſte either of the Pulp, of the Peach, or of its Kernel. There are Soils that communicate a peculiar Taſte to the Fruits that grow upon them, but then this Taſte is given equally to all Fruits, and is perfectly different from their own, which each has beſide. In this Caſe the Earth has a Taſte, which it communicates univerſally; but the ſame Effect is produced beſide in the Veſſels of the ſeveral Trees, and Plants, as in other Places.

In the moſt ſtrict and accurate Examination of the Roots of Plants, we find no Preparation for receiving particular Juices. GREW ſhews that the Surface of Roots is a ſpungy Subſtance, which muſt receive all Juices alike; and the Surfaces of all Roots are ſuch. Theſe ſpungy Openings receive the fine Particles of Earth for Nouriſhment, and the Organs of the Plant give them their Differences in the different Kinds, as well as in the various Parts of the ſame.

Plants of the moſt different Kinds may be raiſed in Water, and they will all have their particular Forms, Taſtes, and Colours. Will theſe People ſay that there are in Water different Juices to be taken up by different Plants? that were abſurd. We ſay there are Particles of Earth in all Water, which is a known Fact: and that theſe are taken up by the Roots of Plants for their Nouriſhment: that they are in themſelves perfectly alike, and are taken up indifferently by all, but that they are changed in the Organs of the Plants, in order to give them their Forms, Taſtes, and Colours: this ſurely is reaſonable.

The Advocates for particular Juices affirm farther, that as there is a Neceſſity for a diſtinct Juice for nouriſhing each ſeveral Part of the ſame Plant: it cannot be but that the Roots of every Plant are ſo formed, that they will receive or admit no Juices but ſuch as are ſo appropriated to that Plant; and that the ſeveral Parts of the Plant afterwards appropriate again ſuch Juice as is alone ſuitable to them.

No Doubt but according to the Syſtem of different Juices, this ought to be the Caſe; the Queſtion muſt remain whether it is: and on the Deciſion of that, the whole Objection may reaſonably be ſaid to ſtand or fall. Mr. TULL has produced an Experiment on this Occaſion, the Reſult of which, as he relates it, is altogether deciſive; and deſtroys that Opinion entirely. The Experiment is this. Set a Stalk of Mint in a Glaſs of Water: it will grow there and ſhoot out many Roots. Let ſome of theſe Roots be got out of the freſh Water, and plunged into a Glaſs of Salt Water: in this Caſe the Mint will preſently die, and its Leaves will taſte ſalt.

In this Caſe there is no Doubt but the Mint is killed by the Effect of the Salt Water upon its Roots; becauſe if the ſame Roots had been cut off, the Plant would not at all have ſuffered: and the ſalt Taſte of the decayed Leaves ſhews plainly, that the Salt was the Cauſe of its Deſtruction. This Fact reſts upon the Credit of Mr. TULL, who has related it: and he aſſerts from it very fairly, that it is a Proof that Roots take in indifferently any Nouriſhment that comes in their Way, even when it is of a Kind that will deſtroy the particular Plant they are to feed.

CHAP. IX.

Reaſons deduced from the Practice of Huſbandry.

THE Practice of the Huſbandman, and its Succeſs, 'tis ſaid, prove that there are different Juices taken up out of the Earth for the Nouriſhment of different Plants. Why, ſay they, are Barley or Oats ſown after Wheat, and not Wheat again, if it were not that the Wheat has drawn all the nouriſhing Juice fit for its Kind, ſo that the next Crop of the ſame Species would be ſtarved; whereas there ſtill remains in the ſame Ground, the nutritive Juice fitted for Barley, and that for Oats, which therefore flouriſh, though a ſecond Crop of Wheat would not.

It has been anſwered already, that the real Cauſe of this is, that Wheat requires and takes up a large Quantity of Nouriſhment, ſo that there does not remain a ſufficient Stock for a new Crop of it; but that the ſame Land will raiſe Oats and Barley becauſe they require leſs: but to this we ſhall add here, that if it were true that the Cauſe of Barley growing well after Wheat, were that the Wheat had left in the Ground the Nouriſhment proper for Barley; then in Conſequence a good Crop of Wheat might be expected after Barley, becauſe the Barley would have left in the ſame Manner the Juices proper for Wheat, and the Ground would be, in this Reſpect, the ſame as if nothing had been ſown in it before. But this does not anſwer in Practice, and we may therefore be ſure the Theory is not true. Such a ſowing of Wheat would yield a very bad Harveſt. The Truth is this, Wheat does not ſucceed well except the Land have had four Workings: if Barley were ſown in Land ſo prepared, it would ſucceed greatly, but as it does not bear the Price of Wheat, nor require ſo much Preparation, they ſow it after two.

Barley will grow upon Land that has been impoveriſhed in ſome Degree by another Grain, therefore it ſucceeds after Wheat; but Wheat will not thrive unleſs it have the Land freſh, and thoroughly prepared to give it Nouriſhment, and it is therefore Wheat will not do after Barley.

If it were true that every Plant drew from the Earth a particular and appropriated Juice for its Nouriſhment, and no other; what Occaſion could there be for that antient Practice of letting the Lands lie fallow one Year in three, as is the Cuſtom in common Fields. If that were the Caſe, they might inſtead of this Time of Reſt, only give a Change of Crop. Thus if they ſowed Wheat the firſt Year, Barley the next, and Oats the third, and then Peaſe and Turnips; they might after this laſt Growth ſow Wheat again, the Land having had five Years to recover the Nouriſhment of Wheat: but this is not found in Fact, nor is there any Truth in the Argument that would ſupport it. The Nouriſhment of all theſe Plants is the ſame, and is no other than Earth in very ſmall Particles, and there is no other Difference between them, but that one Kind draws more of it than another.

Every one the leaſt acquainted with the Practice of Huſbandry knows, that in ſuch a Courſe as here deſcribed, all the Crops would grow worſe and worſe, till they would not be worth gathering: and this, becauſe all Crops exhauſt the Earth of the general Nouriſhment of Plants, though in a different Degree.

Beſide this the Reſt is not all that Land has during the Intervals of Crops for its Recruit. It is in this Time turned and worked, by which Means the Particles are anew divided, and there is a freſh Supply of ſmall ones procur'd for the affording Nouriſhment to the following Growths. The Texture of the Mould is broken ſo, that it gives free Paſſage again to the Roots of Corn in new Places; and by all this it is render'd proper for the Production of ſuch Plants as require a great deal of Culture, ſuch as Wheat particularly: and during the whole Time of this Reſt and Preparation, it is not ſuffer'd to be exhauſted by uſeleſs Plants.

If it were true that every Plant drew from the Earth a particular Juice for its Nouriſhment, which ſuited its Purpoſe, and that of no other Kind, then Thiſtles, Bluebottles, Corn Marygold, and the other Weeds ſo frequent among Corn, would do it no Harm; becauſe they would take only ſuch Juices as the Corn would not: but juſt the contrary is found in Fact. All theſe Plants do injure the Growth of Corn, and that, becauſe they all exhauſt the Earth of its Nouriſhment, which is the ſame for one and for the other.

If other Plants did not draw from the Earth the ſame Nouriſhment with Corn, then Corn might as well grow among the largeſt Cluſters of them, as ſingly in a Field: but we find it will not: and 'tis not to be pretended the Stalks of the Plant prevent this any Way, becauſe ſo many Sticks of dry Wood will do no Harm.

CHAP. X.

The Reſult of Experiments in Vegetation.

MANY have thought that every Thing that can be diſſolved in Water, enters indifferently into Plants; and that each ſeparate Kind, of all theſe Things, appropriates only what properly belongs to its Nature, and lets the reſt all paſs off by Tranſpiration.

This, like many other of theſe Reaſonings, has a very fair Appearance, but it cannot ſtand before Experiments. We can collect what paſſes off from Plants by Tranſpiration: Dr. Hales has done it, and the Reſult has altogether contradicted this Syſtem. Seeing what great Quantity of Matter perſpir'd, ſays he, I was deſirous to try if I could get any of it. I fix'd Glaſs Retorts to Trees of different Kinds, taking in their Boughs with the Leaves on into the Retort, and ſtopping up the Mouth about them. By this Means, ſays he, I got ſeveral Ounces of the Matter perſpir'd by Vines, Fig Trees, Apple Trees, Cherry Trees, Apricot and Peach Trees, alſo by Rue, Horſe-

radiſh, Rheubarb; and by Parſnips, and Cabbage Leaves. The Liquor of all of them was very clear, nor could I diſcover any different Taſte in the ſeveral Kinds: and the ſpecifick Gravity was very nearly the ſame with that of common Water. Here was a great Variety of Plants and Trees try'd, and if there were different Matters to be tranſpir'd, theſe certainly muſt have ſhewn that Difference, but upon this fair Experiment there appear'd no ſuch Thing, the Liquor obtain'd from them was in all Reſpects the ſame, it was perfectly like common Water, and ſhew'd no other Difference from it, than that it would ſtink ſooner: this ſhew'd that it took ſomething from the Plants, but the ſame from all. Having paſs'd through their Veſſels it acquir'd ſome vegetable Quality, but that was the ſame from any Plant. This Experiment is the ſeventeenth in Dr. HALES's vegetable Staticks, it is eaſily repeated; but the Authority of that Writer is ſufficient to eſtabliſh it; and it overthrows perfectly that Syſtem of the Plants taking up ſeveral Kinds of Juices, and letting all but the right tranſpire.

If this were the Caſe, that each Plant took up all that could be diſſolved in Water, and tranſpired what it did not want, the Ground would be continually exhauſted. For what was thus tranſpired would float in the Air, and be at the Mercy of the Winds, to carry which ever Way they chanc'd to blow.

Thus eaſily are theſe Objections to the Earth itſelf being the Matter of Nouriſhment to all Plants, anſwer'd; but there remains a farther Obſervation to be ſtated: as this will fall within the Farmer's immediate Notice, and is of much greater ſeeming Force than any of the former, it ought to be propoſed fairly in this Place, where we are enquiring after Truth for the Service of that uſeful Art.

The Huſbandman will obſerve, that when his Land which would no longer bear Corn well, has, for ſome Years, bore Saintfoin or Lucerne, it will again bear great Crops of Wheat. This ſeems to ſhew, that the Subſtance neceſſary for nouriſhing Wheat, and that neceſſary for nouriſhing of theſe Graſſes is different; and conſequently that the Food of all Plants is not the ſame. And in farther Support of this Argument it may be obſerved, that Grounds which are laid fallow, to give them Strength for Corn, bear in that State great Quantities of Weeds. This ſhould ſeem alſo to ſhew, that different Juices in the Ground are fit for the Nouriſhment of different Plants; and that it is not the Subſtance of the Earth which ſerves for all. This is what theſe Obſervations ſeem to ſhew; but let not the induſtrious Enquirer ſtop at Appearances, but proceed to a deeper and a fairer Search.

In purſuing this Subject we find, that thoſe Lands which are only left fallow, and have nothing done to them, do not improve either ſo quickly or ſo perfectly as they would have done, if they had been well wrought and tilled during that Interval.

We find alſo, that the greater Part of thoſe Plants which grow upon fallow Lands, are Weeds of ſlight Roots which ſpread juſt under the Surface, and do not penetrate to any Depth; and conſequently, that when theſe Lands are wrought, and the lower Part of the Soil is turn'd up, this is Land which has lain in abſolute Repoſe. Now the contrary to this happens when Saintfoin and Lucerne are ſown, for they root very deep: but for that Reaſon they do little Prejudice to the Soil near the Surface; for it is found by Experience, that theſe deep-rooted Plants draw their Nouriſhment from a great Depth, and leave the ſuperficial Parts of the Earth unexhauſted.

Thus when we ſee the full Extent of this Objection to our Syſtem, it ceaſes to be any Objection at all. In the Caſe of Weeds on Fallows, they exhauſt the Surface only, and that Surface is turned downward in plowing; ſo that the Earth which is turned up for the Growth of the Corn, is not exhauſted by them. It has lain its Year in Repoſe, and is now fitted for the Nouriſhment of Corn, by turning and breaking. The Saintfoin and Lucern root very deep, and draw their Nouriſhment from the lower Part of the Land; ſo that a Field cover'd with theſe Graſſes, has the upper Part of its Soil in a State of Repoſe; and when that comes to be wrought and turn'd up, it is freſh and fit for the Nouriſhment of Corn, for Corn is the moſt ſuperficial of all Growths in its rooting. Thus the Caſe is not that Weeds and Saintfoin draw only a particular Nouriſhment, and that different from the Food of Corn, that makes Corn ſucceed after them; but it is that the firſt exhauſts the Surface of the Earth which is turn'd undermoſt in plowing, and the latter exhauſts the Earth at Depths whence it is never turned up for Corn; and all the Time of their Growth, that Part of the Soil in which the Corn afterwards is to grow, lies quiet, they not affecting it.

The Farmer finds by Experience, that Plants with tap Roots do not ſucceed upon Land where other Plants with the ſame Kind of Roots have been. Thus Trefoil or Lucern will not thrive after Saintfoin; whereas thoſe Plants which have ſpreading Roots, ſucceed upon the Lands that have born the deep-rooted ones excellently; 'tis plain therefore, that theſe deep-rooted Plants have exhauſted the Earth of its Nouriſhment at thoſe Depths, but not at the Surface. 'Tis extreamly probable therefore, from all Appearances, that the Nouriſhment, or Food of all Plants, is the ſame, and that it is nothing but Earth in ſmall Particles. We ſee that Plants of any Kind exhauſt this Nouriſhment, according to the Depth at which they root; and no otherwiſe. When this Nouriſhment is exhauſted, the Earth muſt be prepar'd in order to the giving more; and as it conſiſts only of ſmall Particles of Earth, any thing that breaks and divides the Land anſwers this Purpoſe. The Effects of the Air do this in fallowing; the Plow does it in turning and labouring, and the different Manures do it by fermenting the Soil. All theſe Things produce the ſame Effect, by ſeveral different Ways, and conſequently in different Degrees; but of this the Farmer may be ſure, whatever will break and divide the Particles of Earth, will make that Earth proper for the Support and Nouriſhment of Plants.

CHAP.

CHAP. XI.

Of changing of Crops.

HAVING thus explained to the practical Husbandman the Nature of the principal Parts of Plants, and of their Nourishment, he will easily understand the Reasons of all that shall be proposed to him for the Improvement of his Profession: and, where any thing at all out of the common beaten Road was to be proposed, this Explanation was needful.

We see plainly, by the preceeding Observations, that all Plants are nourished by the same Substance; that every Plant will exhaust the Earth of its Nourishment, which would be fit for others of the same Growth; and that a Piece of Land which was once fit for the nourishing and supporting a Crop of any Plant, will continue to support and nourish Crops of that Plant for ever, if it be properly tilled and managed.

This last is an Article of great Consequence, and perhaps little believed by the common practical Farmers, but it is equally true with the others. It is seen to be so by Reason, and may, at any Time, be proved by Experience. Let those who would deny it, first try.

From this we see that it is not necessary to change the Crop every Year, upon the same Land. This plainly makes way for a new Method of Husbandry, and for vast Improvements in that useful Art. It is on these Facts that the Horsehoeing System has its Foundation; and being built upon Truth it must remain for ever.

We do not deny that in following the common Practice of Husbandry, there is a great Advantage in the sowing successively different Species upon the same Land. We have shewn, however, that this is not owing to the commonly supposed Cause, that each exhausts the Earth only of its peculiar Nourishment, leaving the proper Juices for the others; and we shall now explain that Matter farther.

There are three Causes which may occasion this good Effect of changing of Crops, in the common Method of Husbandry; but all of them different from this supposed Cause in the different Nourishment. The first is the different Quantity of Nourishment that is requir'd for different Plants, as has been hinted generally before; a second is the different Constitution and Formation of Parts in each particular Plant, some being much more delicate than others; the third is the different Quantity of Tillage which each Kind of Crop requires should be bestowed upon the Ground. These are the real Causes why a second Crop upon the same Land, should be different from the first, and a third from the second, although the Nourishment of all be the same.

All Plants do not draw from the Earth the same Quantity of Nourishment: this is plain, for there are poor and light Lands which nourish Rye very well, though they would not yield a Crop of Wheat, nor even of Oats. On the other hand, there are Plants which are able to plunge their Roots into a hard Soil, into which others cannot penetrate. The Roots of Oats will penetrate a hard Land better than the Roots of Barley, and therefore Oats will grow with less Tillage than Barley. This is seen in Experience, for Oats succeed tolerably well in many Places, where the Soil is hard, with only one dressing: Whereas Lands that are much lighter and softer, require two Dressings, in order to produce a good Crop of Barley.

From this Observation we may conclude, that in following the common Practice of Husbandry, some other Corn should be sown for the next Crop after Wheat; because Wheat requiring several Dressings of the Land, in order to yield a good Crop; and requiring also to be sown in the Begining of Winter, or soon after Harvest, it would be impossible to give the Land those necessary Dressings for it, without which we know, from Experience, it will not succeed. Here is a plain Reason for the changing the Crop in the common Method of Husbandry, without having Recourse to that idle and false Cause of the different Nourishment requir'd for different Plants. For with Respect to Oats and Barley, as they are not to be sown till the following Spring, there is Time between the gathering the Wheat Harvest, and the Season of sowing them, to give the Land the one or two Dressings which they severally require; though it would be impossible, in the short Time between the reaping of Wheat, and the sowing it for the next Crop, to give the Land the four Dressings needful for that Corn.

The Years Fallow that is given to prepare for Wheat, gives perfect Opportunity for those four Dressings, and for all the Advantages which the Land receives from the Air and Rains, between one of them and the other.

If any one should take a Resolution of always raising Wheat upon the same Land, he must sow it only every other Year. The Year between must be a Year of Fallow, for the giving the Land its four Dressings; and in this Manner the same Land would for ever yield large Crops of Wheat, without ever sowing any other Corn.

Mr. TULL produces an Instance which sufficiently shews that Wheat will not, in any Condition, succeed upon Land that has not receiv'd its proper Number of Dressings. He says, That on sowing a Piece of excellent Land with Wheat, in the usual Way, it grew so thick and heavy that it lodg'd, and little Grain was got at Harvest: after this the Owner seeing the Richness of his Land, thought that it would bear Wheat any Way, and giving it only one Dressing, sowed Wheat again, expecting, that as the Growth would be now less strong, he should have a better Harvest; but he was disappointed, he hardly obtain'd from it the Quantity of his Seed Corn.

Wheat is found to succeed very well after Turnips; and People from this have fancied, that the Nourishment of Turnips was different from that of Wheat, and that they did not exhaust the Earth at all of what should serve that Corn: but he who has consider'd what we have already said of Wheat, will see this is owing to a very different Cause. The great Requisite for Wheats

ſucceeding is, that the Ground be very well dreſs'd by Tillage. The Turnips are ſown on Ground that has been very well wok'd; and it is dreſs'd over again as they are growing: therefore, when the Wheat comes to be ſown afterwards, it has a Land different from what it commonly is allow'd, but different in the right Manner, for it is more labour'd and dreſs'd than in the cuſtomary Way.

Farther it may be obſerv'd, that Turnips exhauſt Land very little, unleſs they be ſuffer'd to run to Seed. Nor is this all: we find that the Nouriſhment the Turnip does exhauſt, is little more than Water, ſo that leſs of the earthy Matter going into them, the more is left afterwards for the Wheat. This Fact may be prov'd by Experiment on the Roots themſelves. If a large Quantity of Turnips be mix'd with Wheat Flower, and made into Bread, when the Bread after baking comes to be weigh'd, there will be found very little more of it than if the ſame Quantity of Flour had been uſed without any Turnips.

From this it appears, that if Turnips are ſown upon a Land intended for Wheat, and eaten off before they run to Seed, the Land is only better prepar'd for that Corn by their Growth, not being in any conſiderable Degree exhauſted of its nouriſhing Particles; and at the ſame Time the Cattle eating theſe Turnips upon the Spot where they grow, their Dung and Urine add greatly to the Richneſs of the Ground.

When Saintfoine has grown upon a Piece of Ground, there muſt be proper Care in the introducing Wheat upon it. This Ground not having been dreſs'd or turn'd for nine or ten Years, while the Saintfoine was upon it, will not be ſufficiently broken by one or two Dreſſings, for the nouriſhing a good Crop of Wheat. One or two Dreſſings after this Graſs will prepare the Ground very well for Oats: but more are altogether neceſſary for the Succeſs of Wheat.

Upon theſe Principles we ſhall find, that although in the ordinary Way of Huſbandry, it is impoſſible to have Wheat every Year upon the ſame Piece of Ground, with any Degree of Succeſs; yet in the Method of Horſehoeing Huſbandry, it may be done. All that we have been here premiſing, is for the Explanation and Recommendation of that Practice of the Farmer; from the which, managed with Prudence, according to the Directions we ſhall lay down, he may, in moſt Caſes, make a much greater Advantage of his Land than in the common Methods. By this Practice a Crop of Wheat may be advantageouſly rais'd every Year upon the ſame Ground, and the Means upon which this will depend are, to give it more Dreſſings; in order to break and divide the Particles of the Earth more perfectly; to put the Plants in a Condition to ſpread their Roots in this prepar'd Earth in the moſt advantageous Manner, for the obtaining the Nouriſhment wherewith it abounds; to prevent Weeds from robbing the Crop of its Nouriſhment thus afforded by the Ground; and to be careful not to raiſe upon the Land more Plants than can be ſubſiſted well upon it. Theſe are the Principles on which the Practice known by the Name of Horſehoeing Huſbandry depends, and every one muſt ſee, that theſe are founded on Reaſon, and on what is ſeen in the Growth of Plants in every Way in which they are rais'd. This has the ſure Ground of Experience, and therefore cannot fail.

CHAP. XII.

Of the Diſtribution of the Nouriſhment of Plants in the Earth.

WE have ſhewn the great Advantage of a Year of Fallow is, that it gives Time for a ſufficient Number of Dreſſings, for the Deſtruction of Weeds, and preparing the Land for Corn. Theſe Dreſſings muſt be at proper Intervals, for otherwiſe they have not half their Effect. Between one Dreſſing and another, the Weeds that are plowed in ſhould have Time to rot, and the Earth new turned up to receive the Benefits of Sun and Rain. A ſecond Dreſſing coming immediately after the firſt, would only throw up the ſame Land again, undoing what the firſt had done in a great Meaſure.

From what has been ſaid on this Subject, the conſiderate Reader will underſtand not only the Neceſſity of Dreſſings for Land, but the Nature of their Benefit: and in purſuing this we ſhall naturally fall upon the Subject of the preſent Chapter, which is the Diſtribution of that Nouriſhment we have deſcribed in the Earth.

However good a Soil may be in its Nature, the Plants ſown in it can have very little Advantage from its Richneſs, if their Roots cannot ſpread and penetrate it to get at the Nouriſhment. A Soil that is too firm will not permit this, its Riches are as if they were lock'd up; and it muſt be broken by Dreſſings. The vaſt Fertility of Garden Ground is owing in a great Meaſure to this continual ſtirring and breaking of it in digging; and we ſee in the ſame Manner that all Earth is fruitful that is frequently mov'd and broken. We may therefore ſafely eſtabliſh it as a Principle, That the more the ſmall Particles of a Soil are divided, the more its inward Pores are multiplied, and it is in Proportion render'd the more fit for the Nouriſhment of Plants. We have ſaid already how great Things may be done for the Improvement of Land by Manures, we now come to the Article of Dreſſings, for on the proper Underſtanding of theſe two Things depends all the Knowledge of Huſbandry. The common Practice reſts moſt upon Manures; the Horſehoeing Huſbandry on Dreſſings of the Land by Labour and Tillage: this is their great Difference.

The Nouriſhment of Plants, we ſee by Experience, is ſpread throughout every Part of the Earth, but it would there anſwer no Purpoſe to us if Plants were not able to draw it, and take it in for their Supply. To this Purpoſe it is neceſſary, that they have the Means of ſpreading the ſmall Fibres of their Roots between the ſeveral little Particles of Earth in a Soil. Land in which theſe Particles are preſſed too cloſe, or connected too firmly together, pre-

vents this Paſſage of the Roots; but it appears altogether neceſſary that there be Spaces between theſe Particles into which thoſe Roots may run. Moſt Soils have naturally theſe inward Pores, but frequently they either are in too ſmall Quantity, or they are not of proper Kinds and Proportions for the admitting and ſupplying the Roots. This is the natural Defect of Soils, and this is to be remedied by Dreſſings.

When the Pores are in too ſmall Number, it frequently is found that there is no Communication between one of them and another; and by this Means the Roots are ſtop'd in their Paſſage, and cannot get at the Nouriſhment that is ready for them in other Places, nor obtain enough for the Support of the Plant. This is the Fault of too ſtiff Soils.

On the other hand when the Pores are too large, the Roots go through them almoſt without touching the Earth, they therefore can take no Nouriſhment from it: this is the Fault of too light Soils.

Theſe are the Defects of the Generality of Soils, and theſe may be remedied by Culture properly conducted: for the Earth contains ſo great a Quantity of Nouriſhment, that there is no Need to fear exhauſting it; the only Buſineſs is to put the Roots into a Condition of getting at it.

Neither are we to fear that this Nouriſhment, intended for Plants, will be ſcattered and loſt of itſelf: Experience ſhews that there is no ſuch Danger. If we dry a Piece of Earth ever ſo thoroughly, and then powder it ever ſo fine; if we expoſe it in this State ever ſo much or ſo long to the Sun, Rains, and Froſts, it will not have its nouriſhing Particles diſſipated or loſt by this; but all that Management will render it more and more fertile. This is a Proof that the Nouriſhment it affords is real Earth, Water is neceſſary to be mix'd with thoſe Particles of Earth, which are the Nouriſhment of Plants; and in the common Courſe of Things, when this has carry'd up the nouriſhing Particles into their Veſſels, it is tranſpir'd through their Leaves, leaving thoſe Particles behind. This is the Courſe of Nature in the ſupplying of Plants: but when Water is evaporated from the Earth, without paſſing with it into the Veſſels of Plants, it goes off alone, taking with it none of thoſe nouriſhing Particles. This is plain from what we have before obſerved, that Lands which are left fallow grow more rich and fertile; whereas, were the Water that is evaporated from them to carry the nouriſhing Particles of the Earth along with it, they would be rendered poorer by this Practice.

In the Management of Land for giving it Fertility, what we are to aim at, is not ſo much to provide or ſupply Plants with ſuch Particles as are needful for their Nouriſhment, as to diſpoſe them in ſuch Manner that the Plants can gather thoſe Particles they poſſeſs, with their Roots. Almoſt all Soils contain of themſelves the Nouriſhment of Plants in Abundance, what the Huſbandman is to do is, to put them into a State fit to afford it to their Wants.

The great Article in bringing this about, is a proper dividing and breaking of the Particles of the Earth; this muſt be done in ſuch a Manner, that thoſe Particles may leave between them as great a Number as poſſible of little Spaces, into which the Roots may inſinuate themſelves, in ſuch a Manner, that immediately touching the Particles of Earth, they may gather from them thoſe extreamly fine and minute Parts, which are their real and proper Nouriſhment or Food.

This breaking and dividing of the Soil is to be done, as already ſaid, two Ways, by Manures and by Tillage: we ſhall, in the ſucceeding Chapters, examine impartially and ſtrictly by which of thoſe Means it may be beſt obtain'd; for on that depends the Merit of one or the other Kind of Huſbandry; and it is by underſtanding their different Operations alone, that the practical Farmer can be directed in his Choice, which Method to prefer on any particular Occaſion; and how to manage his Ground to the greateſt Advantage. This it is the immediate Purpoſe of our Work to inform him; and we ſhall therefore give a fair and candid Repreſentation of every reaſonable Method that has been propos'd for this Purpoſe.

BOOK VI. PART II.

Of the Advantages of TILLAGE.

CHAP. XIII.

Of the ſeveral Methods of dividing the Particles of Earth.

WE have ſhewn, in the preceding Chapters, that the Means of giving Fertility to a Soil, conſiſts in the dividing and breaking of its Particles. We are now to examine in what Manner that Effect may be beſt produced; and we ſhall do this with Impartiality. The favouring a particular Syſtem may miſlead Men, but they are ſafe from Prejudice who have no Aim but the Diſcovery of Truth.

There is, beſide the two Ways already mentioned of dividing the Particles of Soil, which are Tillage and Manures, another to be remembered here, which is Heat, or the Effect of Fire. The Difference is this, Tillage operates mechanically, breaking thoſe Particles merely by the Inſtruments employ'd in it; Fire acts in the Way of Calcination; and Manures by Way of Fermentation.

Dung, which is the principal amongſt Manures, always alters in ſome Degree the Nature of the Productions; and there is beſide another Diſadvantage in this Reſpect, which is, that we cannot pro-

procure it always in the needful Quantity. On the other hand, it is always in our Power to increaſe the Tillage as much as we pleaſe, and this never alters the Quality of the Productions; Dung and other Manures may give ſome Subſtance to the Earth; but repeated Dreſſings by Tillage expoſe one after another, the different Parts of the Ground to the Influences of the Sun, Air and Rains, and theſe render it in a ſurprizing Manner fit for the affording Nouriſhment to Plants.

It has been ſhewn already, that the more we break the Particles of the Earth, the more we increaſe the Number of its inward Pores; the more we increaſe the Surface of thoſe Particles, the more we put the Soil in a Condition to furniſh Plants with Nouriſhment: that is, the more we add to its Fertility.

We ſee it is in our Power to effect this by Fermentation raiſed by Means of Manures, or by the Inſtruments of Tillage; and that the Uſe of Dung is limited, becauſe the Quantity is limited; but the Method by Tillage is without Limitation, becauſe we may give as much as we pleaſe.

That Dung has the ill Effect of ſpoiling the Taſte of the Products of the Earth in ſome Degree, is proved by its Effect in Kitchen Gardens. The eatable Plants raiſed with Dung being much worſe taſted than thoſe without. The Cabbages and Pulſe are never ſo well flavoured in great Towns, where they are raiſed with Abundance of Dung, as they are in the Country where Dung is ſcarce, and leſs of it is uſed in rearing them. And in the Wine Countries this Effect is the moſt obvious of all, the Difference being ſurprizingly great between Wine made from the Produce of a Vine that has been dunged, and that from the Grapes of the ſame Kind where there has been none of that Manure uſed.

Theſe are the real and certain Diſadvantages of Dung, eſpecially when uſed in too great a Quantity: Mr. Tull has carried this Point much farther. He attempts to prove that Dung gives hurtful Qualities to the Plants raiſed by its Aſſiſtance: but the Fondneſs for his Syſtem carried him in this a little too far; and it muſt be obſerved, that his Arguments are not concluſive.

It is probable, on the contrary, that a poiſonous Plant would have leſs Power when raiſed in a rich dunged Soil, than in the pooreſt natural Earth; for we find Dung, though it increaſes the Growth of Plants, weakens their Qualities, and even their Taſtes.

Dung acting by Fermentation makes an inward Diviſion of the Particles of the Earth, which muſt needs be uſeful in giving it Fertility; but the Inſtruments of Tillage break thoſe Particles, and at the ſame Time do ſomething more: they change their Place, they turn about the larger Parts of the Soil, and give them all the Advantage of the Seaſons, at the ſame Time they deſtroy Weeds. The Improvement therefore which is made by Tillage has many Advantages, whereas that made by Dung has but one. The Earth thus dreſſed is not exhauſted by uſeleſs Plants; and it receives from Time to Time, and in all its Parts ſucceſſively, the Advantages of the Dews, Rains and Sun, all which we ſee, from manifold Experience, aſſiſt greatly in giving Fertility to Land.

A great Diſadvantage attending the Uſe of Dung is, that it draws Inſects together which eat the Produce. When Trees are planted in a dunged Ground, it is always found that their Roots ſuffer by Inſects; and the curious in Flowers have for the ſame Reaſon baniſhed the Uſe of this Manure from their Practice.

A very good Method to remedy this Evil, where Dung is found proper to be uſed, is to mix Lime with it in the making up the Heap. Let a Layer of quick Lime be firſt laid for a Foundation to the Heap of Dung, and then as the Dunghil riſes by the Addition of freſh Quantities, let there be here and there a Layer of Lime ſpread between. This will not only deſtroy thoſe miſchievous Inſects which the Dung frequently brings with it, but it will alſo kill in great Part thoſe Seeds of Weeds which are one Way or other received among the Dung, and produce them too often in Abundance among the Corn.

It is repreſented as a great Advantage of Dung, that it is equally uſeful on all Kinds of Soils, the light and the heavy: and there are very few Exceptions to this; but the ſame is to be ſaid in favour of Tillage: for it equally agrees with the ſtiff and the looſe Soils; and improves and gives Fertility to them all.

Stiff Soils have their Particles ſo cloſe to one another, that the Roots of Plants cannot make their Way, or penetrate them ſufficiently; and it is well known that when the Roots cannot penetrate and ſpread in the Earth, the Plant languiſhes. Now when theſe Lands have been broken and divided by Tillage, and their Particles thus ſeparated from one another, ſo that the Roots find Paſſage among them, and can ſpread as they ought to ſeek Nouriſhment, they will be able to ſupply the Plants with Food; and we ſhall ſee the Crop grow upon them with Strength and Vigour.

This is the Advantage of Tillage on ſtiff Soils; and it has an equal good Effect on ſuch as are too light and looſe, though in a contrary Way. The Fault of theſe light Soils is, that they have too large Spaces between their Particles, and that many of theſe have not a Communication with one another, ſo that the Roots paſſing through theſe large Cavities, do not reach their Sides; and, conſequently, not touching thoſe ſmall Particles of Earth which are the proper Nouriſhment of Plants, they cannot take them in, and of courſe cannot draw Nouriſhment for the Plant. Now the Effect of Tillage on theſe Soils is this; it breaks the Particles of Earth as in the other, and by that Means multiplies Spaces between the Particles, making a great many ſmall ones inſtead of a few large ones. This it is obvious to Reaſon muſt be the Effect of breaking and dividing a light Soil that has large Intervals; and this naturally qualifies it for affording Nouriſhment to Plants: for theſe ſmall Spaces have their Communications between one another, tho' the larger, from the Nature of the Soil, had not, ſo that the Roots of Plants can penetrate into them, and run thro' them

them as they ſhould; and at the ſame Time touching their Sides every where becauſe of their Smallneſs, they are able to take in thoſe extreamly minute Parts of Earth which we have ſhewn to be the proper Nouriſhment of all Plants.

We have obſerved, that in order to the Roots of Plants receiving or drawing in their Nouriſhment, there muſt neceſſarily be a kind of Preſſure or Reſiſtance between thoſe Roots and the ſmall Particles of Earth among which they run. This naturally happens when the Spaces between thoſe Particles are ſmall, though it could not when they were ſo large as they naturally are in light Soils.

CHAP. XIV.

Of the Degrees of Tillage, and of the Uſe of Dung.

WE have obſerved in a former Chapter, ſpeaking of Dung, that Mr. TULL has endeavoured to prove it uſeleſs on all Occaſions, as well as hurtful on many; and that he is for baniſhing it from the Practice of Huſbandry.

We there obſerved, that the Fondneſs for his Syſtem carried him too far on this Article, and we ſhall here ſhew that he was not ſo far cenſured without Reaſon.

The Origin of the Horſehoeing Huſbandry we have obſerved, is laid in that Paſſage recorded by Mr. EVELYN, where it is aſſerted that nothing more is neceſſary than the thoroughly breaking and dividing the Particles of Earth, in order to make it capable of nouriſhing any Plant: from which it appears that nothing more is uſeful to the giving Fertility to a Soil, than the dividing of its Parts, and breaking the little Lumps into which they form themſelves. This is very true with Reſpect to many Kinds of Soil, but it will not hold good of all: and from this we ſhall ſhew the practical Huſbandman, that there is Danger in his adhering to any Syſtem or Method too ſtrictly; for that although the Benefit of Tillage, in the Manner it is propoſed in the Horſehoeing Huſbandry, may be, and certainly is greater than that of Dung on many Soils, it is not on all. The judicious Farmer in order to make the moſt of every Part of his Land, ſhould be acquainted with every uſeful Method of managing it; but when he knows them all, he ſhould prefer that Kind to each Part which is ſuited to its Nature. 'Tis the informing him in this particular Manner, that is the Intent of the preſent Work: we have laid before him the old Method by Manures, we are here about to propoſe to him the new Huſbandry, which places a particular Kind of Tillage in their Stead; and that he may be able to employ that Knowledge, we ſhall endeavour to convey to him on this Head to the beſt Purpoſe; we ſhall ſhew him, that neither is abſolutely preferable to the other, ſo as to render it entirely uſeleſs; but that one Kind of Management may do for one Land, and another for another: we ſhall ſhew him where Manures will be preferable to the breaking of the Ground by this Method of Tillage, and where this Tillage may be preferable to the common Way by Manures; and ſhall give him ſome Directions alſo with Reſpect to this Tillage; as we already have regarding Manures: ſhewing in what Degree the one, as in what Quantity the other, may be uſeful and neceſſary to particular and different Soils.

Mr. EVELYN has ſaid, that the breaking and dividing a Quantity of Earth, and expoſing it for a Time to the Weather, will render it ſo fertile, that it will ſupport any Plant. On this reſts the Foundation of Horſehoeing Huſbandry, which propoſes to render a Soil fertile by breaking and dividing it with Tillage. But Mr. DU HAMEL declares, that the Fact is not univerſally true, and therefore diſputes the Practice founded on it in ſome Points, while he allows it its Merit in others. He ſays the Aſſertion is not true of all Kinds of Earth, for that he tried it on Clay, and found it did not ſucceed. He powdered a Quantity of Clay, and ſifted it thro' a fine Sieve; but after this, wetting it with Water, it became as tough and ſtiff as it had been originally. This is the Objection ſtated by Mr. DU HAMEL, and though not ſo concluſive as he ſeems to intend it ſhould be imagined, it has its Weight.

In the firſt Place, he has not on this Foundation a Right to queſtion Mr. EVELYN's Fact, for he did not fairly try the Experiment. He ſays he powdered and ſifted the Clay, but he does not tell us he expoſed it to the Weather. This is a Part of Mr. EVELYN's Proceſs, and he ſays it ſhould be ſo expoſed a Year. We have ſeen in the preceeding Part of this Work, that the Effect of Fire in a proper Degree of Calcination, renders Clay fertile. We have obſerved alſo on other Occaſions, that the Sun and Air have in theſe Reſpects the Effect of Fire, only that it is brought about more gradually. Now in this Caſe the powdering of the Clay would have rendered it more fit to receive the Influences of the Sun and Air, and the continual ſtirring and turning of it, which is directed in the Proceſs, would have expoſed every Part of it at Times to their Effect; ſo that it is not eaſy to ſay how much the Proceſs fairly tried would have done toward the rendering even Clay fertile.

However, although the Experiment be ſtated imperfectly, and does not infer ſo much as Mr. DU HAMEL intends; yet this may be properly ſeen from it, that clayey Soils will not be ſo readily improved by this Tillage as the loamy and lighter Kinds; and that other Methods may be needful to be practiſed upon them. Thus the Tillage of the Horſehoeing Huſbandry alone, will be ſufficient for light loamy Soils; and on the other hand, the Farmer who has ſuch as are ſtiff and clayey, will do well to call in to its Aſſiſtance the Effects of Sand, and the other proper Manures; and when that appears neceſſary, of Calcination.

It is in this prudent and moderate Way we ſhall recommend the Horſehoeing Huſbandry to the practical Farmer: and it is thus, and thus only, he ſhould admit the Uſe of any new Methods. Their Authors or Inventors are always partial

partial in their Favour; but that may be very beneficial on many Occaſions, which is not adapted to all.

It is certain that clayey Soils are apt to grow ſtiff again, after ever ſo much Tillage; as has been obſerved in its Place, unleſs aſſiſted by proper Manures; yet we are not for that Reaſon to ſay, that for clayey Soils, Manures are better than much Tillage, for none require ſo much as theſe. Both are required for theſe Lands: a great deal of Tillage to break them, and then good and proper Additions to keep them in Order. 'Tis thus that from very indifferent they become ſome of the beſt Soils we have; and it is thus the Farmer is to manage them. Here therefore neither the old Huſbandry is better than the new, nor the new better than the old, but the true Practice is to join them.

Manures are neceſſary to Clays to keep them in a good Condition, after they have been divided by the Tillage; and they are neceſſary to light Soils becauſe they want Matter of Nouriſhment. They enrich theſe and divide the other: they are neceſſary to both, and they will take double Effect on both, when they are accompanied with good Dreſſings.

CHAP. XV.

Of the joint Advantages of Manure and Tillage.

THESE are the Advantages of Manures, the World has been ſenſible of them at all Times, and it is the Farmer's Intereſt always to continue the Uſe of them, not to neglect them for any other Practice: but this does not make the Horſehoeing Huſbandry, which was meant to ſet them aſide, at all the leſs uſeful. Where Manures cannot be had in due Quantity, this Tillage will, on moſt Soils, ſupply the Place of them; and where they are ever ſo plentiful, it will be a Means of giving them much greater Effect. The Uſe of Manures need not make the Farmer leſs regard his Tillage; for the more the Ground is broken and divided by that Means, the more Effect they will take.

Wheat that is the ſtrongeſt Corn, and requires the moſt Tillage of the Land, ſucceeds yet better when even more is given than uſual; and it is found by Experience, that this may ſupply the Place of Manure. Four Dreſſings are commonly given Land for this Corn, and the Uſe of Dung is added: if the Farmer will give it eight Dreſſings inſtead of four, it will ſucceed as well in moſt Soils without Dung. Theſe additional Dreſſings coſt much leſs than Manures, and when they ſucceed, the Effect is equal. They will at any Time in part, and on many Occaſions entirely ſerve inſtead of Manure, therefore it will be certainly to the Intereſt of the Farmer to uſe them.

Upon theſe Principles it is eaſy to ſee, that there may be Improvements made in the common Practice of Huſbandry. Tillage in the common Way does not anſwer the Farmer's Purpoſe for ſtiff clayey Soils. It breaks the Soil in this Caſe only into a Kind of large Lumps, which have large and irregular Cavities between them; and we have ſhewn from the Nature of Plants, and their Manner of obtaining Nouriſhment, that ſuch a Soil is not in a Condition to ſupport them well. From this it appears, that for the Farmer to uſe theſe Lands to the beſt Advantage, he ought to give them more than the common Tillage; and that by the repeated Dreſſings in the Horſehoeing Huſbandry, he is to break thoſe larger into ſmaller Lumps. By this Means a ſtiff Soil will be brought into the Condition of a light one; and will be perfectly fitted for the Nouriſhment of Plants, or the raiſing a good Crop: Manures are at that Time to be added, and they will be received into the Body of the Soil better than they otherwiſe could; and there will then require nothing more than a Repetition of that Practice which brought the Land into this good Condition, to maintain it in the ſame for ever.

We have ſhewn that Sand is a good Manure for Clay: this proves the Advantage of Tillage on ſuch Lands, for Sand anſwers the ſame Purpoſe in a Manner with Tillage. It breaks the Soil, and lets in the Sun and Rains, and gives Paſſage to the Roots of the Crop. This is juſt what Tillage does, it furniſhes no nouriſhing Matter to the Soil, it only ſeperates the Particles of the Earth; or keeps them ſeperate when they have been broken by Tillage, and this produces all the good Effects we deſire.

Light Soils are improved by Dreſſings, but they need not to be ſo frequent as on the others. To theſe Manures are wanted to give Richneſs, as to the others, to divide and keep the Soil divided: but we need not be afraid of exhauſting the Fertility of theſe Lands, by expoſing them to the Sun: this has been anſwered already, for the Sun evaporates only their watery Parts, not that ſolid Subſtance which is to be the Nouriſhment of Plants. It is certain that all theſe Lands are improved by Dreſſings, and thoſe not in ſmall Number; whether it be that this happens from the breaking of their Particles, makeing them more ready and fit to receive the Dews and Rains, and to receive the Influence of the Sun and Air, or whether from the multiplying their inward Cavities, as Mr. Tull imagines, ſo that they are fitter for the ſpreading of Roots; from which ever Cauſe it riſes, the Effect is certain: and one great good farther attending it is, that by theſe repeated Turnings, Weeds are deſtroyed entirely; whereas light Soils are thoſe which in the common Methods of Huſbandry produce them moſt of all, and that in greater Abundance, from the Uſe of Dung and other rich Manures.

What is here ſaid of the Advantage of turning light Soils, and breaking them by repeated Dreſſings, may be proved by way of Experiment. Let one half of a Piece of Land that has this Soil, be dreſſed in the common Way, and the other be perfectly broken and divided by the Method of Tillage uſed in the Horſehoeing Huſbandry: after ſome Time let the whole Field be turned again in a dry Seaſon, and that croſsways, ſo that the Land may be cut exactly in the oppoſite Direction to what it was

at firſt: in this Caſe we ſhall perceive by the Eye the Advantage of this thorough Manner of Dreſſing, for that half of the Field which had been perfectly tilled before, will have quite a different Aſpect, from that which was but careleſly gone over in the uſual Way: and we ſhall ſee plainly, that the one has had the proper Advantage of Dreſſings, and the others not. We may find the ſame Proof at any Time in the Difference of the Crops on ſuch light Land as has been well laboured, and ſuch as has not, but here it is obvious even to the Eye.

Many have a Cuſtom of breaking the Particles of a Soil with Rollers. This does not deſerve the Name of breaking in Compariſon of what is done in the proper Way by Tillage, but it has its Advantage. When the Land is not too moiſt, it is a very good Method of preparing it for Tilling; but in wet or very damp Lands, the Rollers does more harm than good. Some alſo ſuppoſe that they can ſupply the Place of the proper Tillage by frequent harrowing of their Lands after they are ſowed; but this ſcratching of the Surface of the Ground at beſt can do little Good; and when the Ground is wet it will do a great deal of Harm.

CHAP. XVI.

Of the Preparation of Wood Lands for Corn.

WHEN a Piece of Ground has not been ſown for a great many Years, and is to be prepared for Corn, they call it a new Land: this requires a particular Manner of Dreſſing, and that is to be varied according to the Condition in which they have been before, ſome being heathy, others having lain in Wood, ſome in Paſture, and others in artificial Graſſes. Theſe require ſeverally their particular Methods of Dreſſing; and there are others whoſe natural Humidity makes them demand a Method different from all. Theſe laſt we have conſidered before: we ſhall treat of the others ſeparately, and begin with the Method of preparing a Piece of Land for Corn, that has been covered with Wood.

In the Beginnings of Agriculture, thoſe who ſet about it had much more of this Buſineſs upon their Hands, than we at preſent; a very natural Condition of an uncultivated Country, is to be over run with Wood; and in ſuch a Caſe many found whole Countries who firſt ſet about their Improvement. In this Caſe it was not worth while to fell the Timber, for they would have had no Market for it; ſo they ſet Fire to it upon the Spot, and the Aſhes, aſſiſted by the Action of the Heat, were of great Service in the Improvement of the Ground: after this they had no more to do than to ſtub up; make all level, and go to ſowing.

At preſent Wood is ſo valuable, that it is to be treated in another Manner. When a Piece of this Land is to be turned into a Corn Field, the Trees are felled, the Roots are ſtubbed up, and this is ſuch an Advantage to the Land, that it will anſwer in ſome Degree the Effect of the burning, and of the Aſhes in the other Inſtance: and a little Trouble does afterwards.

We have ſaid in a preceeding Part of this Work, treating of Coppice Wood, that it is a very good Preparation of Land for Corn. It may be often worth while to plant Coppices with this very Intent: but whether that be done, or the Coppice or larger Wood be felled for this Purpoſe, there is no Land that anſwers more happily for Corn, or with leſs Trouble.

The Holes that are made in taking up the Roots, and the reſt of the neceſſary Digging, turn up and break the Land in an excellent Manner, ſo that half the Labour of Dreſſing is ſaved.

In this Caſe, after the Earth has been levelled, there is no Occaſion for more Tillage than this, it is to be turned up once in Autumn with the Plow, the Froſts of the ſucceeding Winter kill the Weeds, and break the Particles of the Soil; and after this no more is needful than a ſecond Dreſſing of the Ground in Spring, and the Land may be ſown, and will yield a vaſt Produce.

This Land that has lain in Wood is not only very fertile at firſt, but it continues ſo a long Time. The Trees have drawn their Nouriſhment from great Depths, ſo that the upper Part of the Ground has lain in a Manner unexhauſted, and the Shade of the Boughs has prevented Weeds from growing in any great Quantity. Beſide this, the Leaves falling every Year, and lying upon the Earth till they rotted, have been for many Years a continual Manure of the richeſt Kind upon the Ground: and the decayed Branches have added to the Fertility, for the ſame Reaſon.

Thus we are to look upon a Piece of Land that has been ſome Years in Wood, as if it had been in a Manner laid fallow all that Time; and the Conſequence proves, that we are not diſappointed in the Expectation from it. A good Piece of Land that has been ſome Time in Wood, will produce vaſt Crops of Corn for many Years, without the Aſſiſtance of the leaſt Article of Manure; dreſſing it but moderately by the Tillage of the Horſehoeing Huſbandry; and that which was originally of little or no Value, and would not have produced Corn to any Advantage, with the moſt expenſive Manures, when it has lain ſome Years in Wood, anſwers beyond Expectation. There are Trees of one Kind or other that will grow on all Kinds of Ground; and there is a certain and very great Advantage from them: this has been ſhewn already. We ſee the Conſequences of that Growth in the Improvement of the Soil, and this conſider'd together, may be ſufficient to lead many who have Lands which they know not how to bring to any Value, to try them this Way. While we recommend this Method, we illuſtrate by the Example, the Practice of Horſehoeing Huſbandry, and ſhew the Truth of thoſe Principles on which we have before ſaid it is founded. We have ſaid that the Roots of Plants ſeek their Nouriſhment near the Surface; and that Trees penetrate for it deeper: this is proved by the Readineſs of a Soil on which Trees have long grown, to yield great Crops of Corn: and we ſee in the Practice by which it is prepared

for this Growth, the great and certain Advantage there is in breaking and dividing the Ground: for all that ſtubbing and digging that is needful in taking up the Roots, ſerves in the Place of ſo much Manure to the Land. The Spade and Pick-axe break the Lumps and divide the Soil, juſt as well as the common Inſtruments recommended in the new Huſbandry; and the Effect is the ſame; for the Land is made fit for the bearing of Corn. Let the Particles be broke and divided, and the Purpoſe is always anſwer'd: it is no Matter by what Means that is done; ſo it be done the Effect is certain.

CHAP. XVII.

Of the Preparation of heathy Land for Corn.

UNDER the Denomination of heathy Land, we here mean every kind of waſte and uſeleſs Ground, that produces Weeds of the worſt Sorts, and is very barren of what is good; ſuch as Tracts of Ground over-run with Heath, Broom, Brambles, Fern, and the like: theſe are the Lands of which we treat in this Chapter, with reſpect to the preparing them for bearing Corn.

It is always proper to burn theſe uſeleſs Productions upon the Spot, as we have ſhewn already under the Article of Burnbaiting. This is ſerviceable, not only becauſe the Heat improves the Ground by a Kind of Calcination, and the Cinders ſerve as a Sort of Manure, but the immediate Effect of the Fire upon the Roots, is a great Benefit, nothing ſo perfectly deſtroying them; nor any other Practice ſo thoroughly ridding the Ground of the Fear of their after-ſhooting. As the Seeds are conſumed, as well as the Roots perfectly deſtroyed, by this Practice, there is great Reaſon to believe they will never riſe again, and this is of the utmoſt Concern, becauſe they are dreadful Enemies to all uſeful Growths.

We have, in another Place, cautioned the Farmer to take Care, that in burning his Stubble upon the Land, he does not fire his Hedges; but a greater Caution is needful here. In firing the Growth of theſe waſte Commons, the Quantity is ſo great, that it is a Body of Flame capable of ſpreading to do vaſt Miſchief. The firſt Care therefore muſt be to know, before the Fire is lighted, where it will ſtop, for it may ſpread much farther than ever was intended or thought of.

When a heathy Piece of Ground is to be thus fir'd, the beſt Method is to clear away a good Space where it is intended to ſtop, by cutting up the Furze and the like; and this will ſtay the Progreſs, though nothing elſe can. At the ſame Time the Stuff that is cut up, being dried, will ſerve to begin the Fire, ſpreading it at the other End of the Ground.

A tolerably calm Seaſon ſhould be choſen for ſetting about this, and the Fire watch'd as it burns. If it any where at the Sides threatens to exceed its Limits, the Method is to dig inſtantly a little Ditch, throwing the Earth upon the Fire. This will preſerve the reſt; for Earth is a much more ſudden and certain Quencher of Fire than Water.

When the Stuff is thus burn'd, the Roots of the Furze and Heath are to be dug up with a Pick-axe, and ſuch others as are firm enough to ſtop or impede the Plow. The Land is then fit for the common Practices of Huſbandry.

The beſt Seaſon for burning the Buſhes is Autumn, and as ſoon as ſome Rains have fallen, the Ground is to be turn'd up in large Furrows, by a ſtout Plow, it is then to lie till Spring; and then, after another plowing, it ſhould be ſown with Oats; the ſecond Year it is to have three good Dreſſings, turning, cutting, and breaking it well every Time; and the third it will be in a Condition to bear Wheat, without any Addition of Manure.

The ſingle Article of Labour, after the firſt Aſſiſtance of burning, does the whole Buſineſs; but this Labour muſt be well perform'd, and ſufficiently repeated; for as the Fertility, in this Caſe, depends principally on the breaking the Lumps, they muſt be well broken, and nothing but this thorough Tillage can prevent the old Inhabitants from taking Poſſeſſion again of the Ground. Notwithſtanding they have ſeem'd ſo perfectly deſtroy'd, they will, after ſeveral Years, recover, to the Deſtruction of all uſeful Growths, if they be not kept down by this Tillage: but this, if properly attended to, will never fail. The Winter turning expoſes the Roots to the Froſt, which nips them, and the Summer turnings ſpread them before the Sun, that burns them up. In general, it is one vaſt Advantage of this Kind of Huſbandry, that no other whatſoever ſo perfectly deſtroys Weeds of all Sorts, and that in all Lands; the annual as well as perennial: thoſe that riſe in Numbers from every Years Seeds, and thoſe that remain from Year to Year by their Roots.

CHAP. XVIII.

Of the Preparation of Land for Corn, after the artificial Graſſes.

WE have obſerved that it may be often proper to prepare an indifferent Land for Corn, by planting it with Coppice Wood: the ſame Advantage that it receives from this Plantation, it may alſo have from the artificial Graſſes that root deep; and from none ſo much as Saintfoin, which penetrates very far into the Ground, and draws very little of its Nouriſhment from near the Surface. We have obſerved that the planting a Piece of Ground with Coppice, is a Kind of fallowing of the Land, with reſpect to the upper Part, or that which is concern'd in the feeding of Corn; and the ſame is the Caſe with theſe deep-rooted Plants.

Many have been ſurpris'd to ſee theſe, and the Saintfoin in particular, grow ſucceſsfully upon theſe ſtony Grounds, which have but a very thin Coat of Soil; but this is no Argument againſt its rooting deep, and thence drawing its Nouriſhment: on the contrary, this Inſtance, when well underſtood, is the greateſt Proof that can be brought

brought of the Truth that this Graſs draws its Nouriſhment deep, and that it does not exhauſt the Land near the Surface, which is the Seat of Nouriſhment for Corn.

When there is this ſtony Bottom to a thin Soil, it is uſually looſe, flaty, or crack'd toward the upper Part, or where it riſes to the Bottom of the Mould: and theſe Cracks and Openings are found, on Examination, to contain Mould of the ſame Kind with that above. The Sainfoin that is ſown in this Soil, ſends its Roots into theſe Cracks and Crevices, and runs among them to a great Depth. From the Earth that is lodg'd in theſe it obtains its Nouriſhment, and ſcarce draws any from the thin Coat of pure Ground above.

Theſe Sorts of Land, when kept conſtantly in Tillage, ſucceed very ill, becauſe the Quantity of Soil is ſo ſmall; for the Roots of Corn never penetrate among the Stones: but the raiſing Saintfoin on them, ſerves as a Kind of fallowing for them. After this Herb has grown ſeven Years on them, which it will very well do, they will yield there good Crops of Corn, and may then be laid down to Saintfoin again very advantageouſly.

Theſe deep-rooted Graſſes are of the ſame Benefit to all Soils, that they are to this light and ſtony Kind; ſome may want the Aſſiſtance more than others, but they are uſeful on all: and after their own great Crops, they prepare the Land for Corn better than almoſt any other Method.

If a Piece of rich Land be drill'd with Saintfoin, ſix Gallons of Seed being allowed to an Acre, and ſow'd in nine Inch Rows, it may be mowed annually with very great Crops; a ſingle Crop ſometimes yielding four Pounds an Acre: and after it has ſtood thus ſeven Years, the Land may be plowed up, and will be ſo rich, that inſtead of requiring to be fallowed or dung'd for Wheat, the Farmer will be obliged to ſow that upon Barley Stubble, and to turn in his Sheep in Spring upon it, to prevent its being too rank.

This, which is a Fact proved by many Inſtances, may ſerve as a Proof of the vaſt Advantage of preparing Lands for Corn by theſe artificial Graſſes; for the Saintfoin will be not only in full Perfection theſe ſeven Years, but would be able to ſtand much longer; and no fallowing would have prepared the Ground for Corn like it.

The beſt Method for preparing the Land for Corn after this Growth is, by firſt ſowing it with Turnips; and I would have my young Huſbandman go through it in this Manner. Let him plow it up in Winter with a four-coulter'd Plough, and get it in order for the ſowing of Turnips for the following Seaſon. When the Turnips rais'd upon it are in Growth, let them be well hoed; and let them be eaten by Sheep, upon the Ground. This will bring the Soil into excellent Order for Barley, in the following Spring.

The Farmer will often find it anſwer his Purpoſe, to raiſe Saintfoin upon a Piece of Ground for a Continuance. In this Caſe, when it grows old he muſt take it up, and ſow Corn to prepare it again. The Method we have here directed is the beſt he can poſſibly follow for that Purpoſe; and when he ſows his Barley it may be done by drilling, and the Saintfoin with it.

The ſame Preparation does when the Land is intended for Corn for a longer Time. In this Caſe let the Huſbandman take Care that the Ground be very well tilled, for otherwiſe the firſt Crops will be very poor. Saintfoin prepares Land excellently for Corn, but there muſt be good Tillage at the breaking of it up, or elſe the Advantage will not be perceived. There have been Examples of this in who have omitted this Care, and they have found the Want of it. Even Oats will not grow upon it to any Profit, without this good Tillage. Some have ſown a broken-up Saintfoin Ground with white Oats, upon once plowing: but if the Summer prove a dry one there will be no Crop at all, and if the Seaſon favour ever ſo much it will be a very poor one.

From theſe Inſtances, which through the Backwardneſs of the Farmers to receive proper Advice, have too often happened, ſome have been led to diſpute whether theſe artificial Graſſes do, in reality, enrich Land or not; but thoſe who will not follow proper Meaſures, when they are pointed out to them, are not to deny the Effects that would have enſued if they had: thoſe who have taken the proper Care in the ſucceeding Tillage, have always found that theſe Graſſes left the Land fit for any Produce. This is ſo plain in Fact, that it has been us'd againſt the Syſtem of Earth being the Nouriſhment of all Plants, and the ſame to all.

It has been ſaid, becauſe Saintfoin leaves the Land rich for Wheat, therefore Saintfoin draws a Nouriſhment different from that of Wheat, leaving what would have been drawn by Wheat all there: but this has been already ſhewn to be an Error.

Some have ventur'd to ſay, that this deep-rooted Graſs ſpreads no Roots or Fibres in the upper Surface of the Earth: and therefore leaves it unexhauſted: this is one great Reaſon, but they carry it too far, who ſay this Graſs ſends out no Fibres into the upper Part at all.

It is true that Saintfoin roots very deep. It has a ſingle long and large Root which penetrates, counting the extreameſt Fibres at leaſt fifteen Foot deep into the Ground, and it doubtleſs draws a great Part of its Nouriſhment from theſe Depths. The Plant does ſend out Roots into the upper Soil, but that is a ſmall Part of the Ground among which it ſpreads, and only a proportional Share of its Nouriſhment is derived thence; ſo that the Caſe being fairly ſtated, this Soil enjoys a Kind of Fallow, becauſe it affords but a fifteenth Part of the Nouriſhment to the Growth that is upon it. This is the true State of the Caſe, and they wrong a good Cauſe who would make it otherwiſe.

We allow therefore that theſe Graſſes do draw ſome Nouriſhment from the Soil in which Corn is to grow, but this is but in ſmall Quantity, and it is over-balanced by another Conſideration, which is the ſecond Crop, or After-Leaſe, being eaten by Cattle upon the Ground. There is a great deal in this: ſo much, that upon the whole there is Reaſon, as well as Experience, to ſhew that a Piece of Ground planted with theſe artificial

Graſſes,

Graſſes, and properly managed in the ſpending of them, and in the Tillage afterwards, is left in as good a State by this Growth, as if it had been in Fallow. It muſt not be objected to this, that the lower Parts of the Earth are not ſo fertile as the upper; ſo that the Roots of theſe Graſſes cannot draw ſuch Nouriſhment from them as from the others; we have allowed for that in the Computation, for we are not to reckon the Soil at a Foot deep; and though this lower Earth is not ſo rich as the upper Part, yet being freſh, and never exhauſted of what it had, it will ſupply a great deal to the firſt that come there: the Roots of Corn never pierce to it, ſo that the Roots of theſe Graſſes are the firſt that come, and they will therefore have Nouriſhment.

CHAP. XIX.

Of the Preparation of Land for Corn, after common Graſs.

COMMON Graſs has not the Advantage of thoſe artificial Kinds laſt deſcribed, in preparing Land for Corn, becauſe its Roots do not pierce to any Depth for their Nouriſhment, but ſpread in a vaſt Quantity near the Surface, in ſuch Manner that it ſhould ſeem they would exhauſt Land more than any other Growth: but this does not prevent the Ground from being very ready to bear Corn, and even to bear it in Abundance, provided it be good in its own Nature.

There is one Reaſon why Paſture Ground retains a Richneſs, that is ready to ſupport and nouriſh any Crop, which has been named in its Place, and needs only be refer'd to here; that is, that in plowed Lands, eſpecially ſuch as lie upon a Deſcent, the Rains waſh away a great Part of the fine Mould; whereas all is retain'd in thoſe cover'd with Sward, and whatſoever is brought on by Accident with it; as the Waſh from higher Grounds, the Mud from the Over-flowing of Rivers, and the like.

For theſe Reaſons a tolerably good Paſture Ground is always ready for Corn, when any one chuſes to convert it to that Uſe.

The proper Seaſon for doing this is in the Month of January; and the Farmer ſhould take an Opportunity to do it after Rains, for when the Land is well wetted, the Turff is tough, and it will hold to turn without breaking, which is an Article of great Advantage in the plowing it.

A very experienced Plowman ſhould be employed on this Occaſion, for no Part of that Buſineſs requires ſo much Skill and Nicety; and the Eye of the Maſter ſhould be over him, to ſee that he lay the Turff he turns up flat and true. If this be done in an artful Manner, one can hardly ſee where the Plow paſs'd, and this is the Proof that it is done perfectly.

But beſide a good Workman there ſhould be a good Plow on this Occaſion; for without that no Art in the Man will make the Work go on well. If the Earth Board do not turn it well, a Piece of Wood is to be nail'd on it, to take the upper Part of the Turff as it riſes; this will never miſs to throw it over with the Graſs Side downward; and the Maſter ſhould look on till he ſee that it be ſo prepar'd, that this Purpoſe is fully anſwer'd.

The Advantage of this is the rotting of the graſſy Part, which decaying, becomes a Kind of Manure, as has been ſhewn already; every vegetable Subſtance, in a State of Decay, being an enriching Article added to the Earth. But this is only the firſt Step toward the preparing the Land for Corn. That is to be compleated by repeated Plowings, and the more of theſe it has, proper Intervals being allowed between one and the other, the better it will be fitted for the Growth of Corn.

This breaking of the Ground by the Plow, or whatever other Inſtrument, is properly what we mean by Tillage; and theſe repeated Plowings are called Dreſſings of the Land. Many uſe the ſame Word to expreſs the laying on of Manures; and in that Caſe alſo, in Concurrence with the common Cuſtom, we have us'd it in that Part of our Work which treats of that Head; here it means only the turning or breaking of the Ground.

Every Time the Earth is thus turn'd, the Particles of which it conſiſts are broken in a greater or ſmaller Number; the more of them the better: and it is on this Principle that the plowing of Lands that have fed a large Sward of Graſs, prepares them for Corn.

We have ſhewn that the Nouriſhment of all Vegetables is fine Earth, which they imbibe from the Surfaces of the little Particles among which their Roots ſpread and run. When theſe Roots have taken up all the fine and ſmall Mould that lay about the Surfaces of thoſe Particles where they ſpread, then the Soil is ſaid to be exhauſted. It may be renewed by the Addition of Manures, which ferment and divide its Parts, or by the Action of the Plow which breaks them; either Way they are broken, and conſequently new Surfaces are made among them. Theſe have new earthy Particles upon them, ready to be abſorbed by the Roots of a new Crop, and therefore a new Crop thrives, being ſown upon that Land.

This is the Doctrine of exhauſting and refreſhing of Land; and it is of the breaking it by the Plow we ſpeak in this Place. This is done in ſome Degree by every plowing, but moſt perfectly by the beſt, and by the moſt frequently repeated. A ſlight plowing moves and divides the Particles of Earth, without breaking many of them; but ſtill this is of Service, for where they are ſeparated one from another, though not broken, there is a new Surface at the Diviſion of them, and this anſwers ſome Purpoſe, though 'tis not ſo much as will be done by better plowing.

We have ſaid, that in the preparing a common Paſture for Corn, there muſt be careful and good plowing; the Reaſon is this, the Ground has lain a great while untouch'd or undiſturbed, and the Surfaces of its Particles have been well drain'd of their Nouriſhment by the Growth of the Graſs. Theſe Surfaces could not yield Nouriſhment for Corn; but when the Ground is well turn'd and divided, the Particles are broken, new Surfaces

are formed, which the Graſs being deſtroyed, does not exhauſt; in this Condition the Corn finds it only improved by the Effect of the rotted Graſs, which ſerves as a Kind of Manure. Therefore in this ſingle Act of breaking up the Ground of a Paſture for Corn, provided it be well done, there is the Advantage of entirely new Particles, and new Surfaces in great Abundance; and of Manure. This agrees with our Plan perfectly, which is not to prefer one Method before another, but to uſe both.

If any one wonder that the ſame Land ſhall continue to be refreſhed by Tillage after repeated Crops, as ſuppoſing that this turning and breaking of the Particles, when repeated ſo often, muſt come to no more than the turning up the old Surfaces again; he errs in the Principle, for the Earth is diviſible without End, and no Art could bring about what he ſuppoſes happens by Accident: the ſame Surfaces never can appear again in a Thouſand Plowings, becauſe the Particles of the Earth form every Time new Combinations; and every new Surface anſwers like the firſt: all ſupply Nouriſhment equally; and every Time the Earth is turned up and broken well, it is like freſh Earth.

Let not the Huſbandman who has a Piece of Graſs Ground to plow for Corn, queſtion whether the Soil be fit for that Purpoſe, for every Soil that will bear tolerable Graſs, will alſo ſupport Corn. Nor on this or any other Occaſion, let him ſuppoſe the Kind of it diſables him from having Recourſe to this Aſſiſtance of Tillage, for we have ſhewn that it agrees with both; and Experience ſhews, that on light Lands two or three additional Plowings will anſwer the ſame Purpoſe as dunging of it; and the Coſt is not more than a fifth Part of the other. This is ſo plain from the Experiments that have been made, that it is getting into Practice in ſome Places, and has obtained the Name of double Plowing.

It has been found, that if a Field prepared for Barley in Spring, be not ſowed with that Grain, but plowed on to Wheat Harveſt, the Crop of Wheat will be ſurprizing; and in the ſame Manner when Crops of Turnips fail one after another by the Fly, the Ground thus frequently plowed, bears Wheat to a Miracle without Dung.

People that are very ſlow to take Advice, will be led by Experience, and this is the moſt plain imaginable. From this Effect of thorough Tillage without Manure, it is extreamly evident that there will require no Aſſiſtance to the Plow in preparing Graſs Land for Corn, only let the Plow not be ſpared. The Work ſets out with a natural Manure, and it will be a great while before the Land, if properly tilled, requires any other: but when it is ſeen to require any, let not the Fondneſs for a Plowing Syſtem deny the Uſe of it: the Benefit ariſing from the Uſe of the four coultered Plow on theſe Occaſions, we ſhall ſhew hereafter in its Place. As much as we here ſay in Favour of Plowing often, we have before ſaid of Manures, and the Farmer ſhould carry both in his Mind together; and uſe the one to the Aſſiſtance of the other, when required, that he may take every Advantage for the making the moſt of his Ground without damaging it for the Owner.

CHAP. XX.

Of keeping Land in Heart by Tillage.

THE Farmer will obſerve that we do not recommend to him to depend upon Tillage only, for the keeping his Land in Condition to bear Corn, tho' that has been propoſed as poſſible, and is ſupported by Experience. Plowing and breaking the Ground will do this, but the Aſſiſtance of Manures will make it anſwer the better. And ſometimes one Method, and ſometimes the other are to be uſed, according to the Circumſtances, as ſhall be directed under the proper Heads.

Having thus premiſed our Advice to have Recourſe to other Methods as well as this, we ſhall now tell him what may be done by this Method alone.

As new broken Earth is the ſame Thing with freſh Earth, to all Intents and Purpoſes, provided it be ſufficiently broken, there is no Queſtion but Tillage will ſupply the Place of Manure; for it will always break the Soil: light Soils, as before obſerved, when well broken by Tillage, become cloſer and heavier, becauſe it brings their Parts nearer together; and heavy or ſtiff Land is made lighter by it, becauſe the breaking and dividing of this, naturally renders it leſs tough, that Fault being nothing but the too great Coheſion of thoſe Particles. But in order to obtain this Advantage for either Soil, the Tillage muſt be ſufficient: for otherwiſe, ſtiff Lands half tilled, have large Cavities, which is the very Fault of too light Soils; and, in the ſame Manner, an imperfect Tillage of a light Soil leaves it rough, and very much of the ſame Nature with the half tilled ſtiff Land: both being in this Condition, full of large Pores and Cavities, which we have ſhewn are not proper for the nouriſhing of Plants.

We mean by this to ſhew the practical Huſbandman, who ſhall in any Reſpect depend on Tillage for the Improvement of his Land, the Neceſſity of ſufficient Tillage, otherwiſe he will deceive himſelf; and perhaps blame that Practice which he has not followed.

The common Kind of light Land, ſuppoſing it to have been in Graſs, as in the laſt Chapter, becomes a great deal lighter for an imperfect Tillage; the Pieces of Turff that remain turned under and not broken, make large Hollows, and increaſe its Lightneſs, and render it in all Reſpects worſe than it was before the Tillage. But when the Farmer has ſuch a Piece of Ground, and finds he has hurt it inſtead of improving it by this Method, let him not be diſheartened, but go on; let him till it more till all theſe Pieces of Turff are broken, and it is altogether fine, and he will then find it anſwer very fully to his Expectations. This Kind of Land has a great Advantage over the ſtiffer Sorts, becauſe it is to be tilled with leſs Labour and Expence, working eaſily: and it anſwers excellently, for it becomes ſtronger than at firſt, and is often more profit-

profitable to the Farmer than Land of a better Kind, that requires more laborious Tillage.

It is obſerved, that in very light Soils Crops ſuffer extreamly in dry Seaſons; and eſpecially after Rains have fallen for ſome Months, as is ſometimes the Caſe; and theſe very dry Seaſons ſucceed. But this Accident happens to them only in Proportion as they have been imperfectly tilled; and when the due Care is taken, not at all.

The Fault of light Lands is the having large Cavities; theſe, when the Ground is wetted by long Rains, are full of Water, and that Water touching the Roots in every Part, ſupplies the Plant with Nouriſhment; but when the dry Weather follows, and they become empty, the Roots do not touch their Surfaces, and cannot be nouriſhed, ſo they fade and decline. But good and perfect Tillage prevents the Earth from having theſe large Cavities, and therefore it remedies this Evil. In theſe, and in all others, the Way to bring them to good, is by beginning with deep, thorough, and good Plowings; and the Way to keep them in Heart is to repeat the ſame Practice.

The Effect of frequent Tillage is to make the Pores or Cavities between the Particles of Earth where the Roots ſpread, numerous and ſmall; they cannot be too numerous, or too ſmall, and therefore the more Tillage is given, the better; for the more there is given, the ſmaller and the more numerous they will be: theſe Pores cannot be too ſmall, when made by Tillage, becauſe the reſt of the Earth being light and looſe, the Roots of the tendereſt and fineſt Kinds will make their Way in them; whereas in a natural or untilled Earth, they may eaſily be too ſmall, and often are ſo, becauſe the Earth all about them is hard. This is the Advantage a tilled Ground has over the beſt natural Soil.

In order to the keeping a Piece of Ground in Heart by Tillage alone, we have ſaid that ſhould be done frequently and well: but theſe are Words at large, and convey little direct Inſtruction, unleſs explained. Nothing is ſo common in Books that teach a Science, as to ſay what is to be done, without telling the Reader how to do it. This is a Fault we hope we have hitherto avoided, and ſhall endeavour to avoid throughout.

The firſt Plowing in the uſual Way anſwers very little Purpoſe, nor does the ſecond do much more good. Theſe two firſt, if done with common Plows, and in the common Manner, cannot ſo properly be ſaid to be Tillage, as to prepare the Land for Tillage: the third and fourth Plowings are done at much leſs Expence than theſe two firſt, and they are of much greater Benefit to the Land: every Plowing that is given after theſe, does more and more Service, and comes at leſs and leſs Expence. This is ſufficient, one would think, to recommend them to the Farmer; and their Effect is certain. We ſee that nothing prepares Land for Wheat in the common Way but frequent Plowings: and when they come thus eaſy, why will not the Farmer give more of them to his Wheat Land, that his Crop may thrive the better; and give them alſo in proper Quantity to his Lands that are prepared for any other Seed, as they will be ſure to return the Labour with ten-fold Increaſe.

When a Land has been put into a good Condition by Manure, nothing aſſiſts the Effect of that Addition ſo much as good Tillage; a Piece of Ground prepared in the common Way with Dung, will be exhauſted in three Years, according to the common Methods; let it have double Tillage, which is an Expence nothing near the Price of a new dunging, and it will keep in Heart ſix Years; and with more, longer.

In ſhort, there is no Way of managing Land to the beſt Advantage, but by the Uſe of both. Manure ſhould be called in when a Land has been long kept in Heart only by Tillage; and Tillage, in this increaſed Degree, ſhould be called in to preſerve and continue the Effects of Manure. Nothing is ſo idle as the propoſing one againſt the other: there is no Reaſon the Farmer ſhould not uſe both, for they never interfere with one another. We hope we have ſhewn him ſo far the Nature of Soils, the Virtues of Manures, and now laſt of all the Benefits of repeated Tillage, that he will be able to call in one or other alone, or both conjointly, as he ſhall find moſt likely to be beneficial.

This is certain as to the keeping a Land in Heart by Tillage, that it is only to be done by allowing it a ſufficient Quantity of Labour: the more it is allowed the better, there being proper Intervals of Reſt between; and this is certain, that a Piece of Ground may be thus not only kept in Heart, but made ſtronger and better; for the finer Land is made by Tillage, the richer it will become, and the more Plants it will ſupport, and the better it will maintain them; that is, the better and larger will be the Crop.

CHAP. XXI.

Of the Nature of the Improvement by Tillage.

THE finer an Earth is made by Tillage, the more it is enriched by the common Advantages of Dews, Rain and Air. Theſe penetrate into every Part of a fine well tilled Piece of Ground, ſo that when it comes to be turned again, and freſh broken, all the new Surfaces that are formed by breaking the Particles, are rich and full of Nouriſhment; this is not the Caſe in tough and hard Lands, for the Dews and Rains do not penetrate them: and this ſhews the Advantage of continued and repeated Tillage.

In very dry and light Lands, the Inſtruments of Huſbandry cannot take Effect in breaking or dividing them, for their Particles give Way to the Plow without breaking, and at the utmoſt are only turned. The Author of the Horſehoeing Huſbandry is aware of this; and he declares, ſuch Lands do not deſerve the Name of Arable, but ſhould be reputed Deſart, ſcarce deſerving the Name of Land, like the Deſarts of Libya, except by way of diſtinguiſhing them from Sea.

This

This is a ſpecious Way of talking, and were there no other Huſbandry in the World but the Horſehoeing Kind, it would be true; and the Farmer who happened to have ſuch Ground in his Hands, muſt leave it uncultivated. But this may ſhew the Inſufficiency of that Author's Scheme of making the Horſehoeing Huſbandry univerſal, even from his own Confeſſion.

We have ſhewn how ſuch Land, as he ſays ought not to be called Arable, and indeed is not capable of being brought to any Uſe upon his Plan, may by another Method of Huſbandry be improved ſo as to yield large Crops; and we may tell his Admirers, that by ſuch Management as has been directed for barren ſandy Lands in the preceeding Parts of his Book, the very Deſarts of LIBYA might be made to yield excellent Crops of Corn.

So eaſy an Addition as Clay to a ſandy Ground, reduces it to Loam, and Loam is fertile; and Furzes may be raiſed for a Fence. In ſuch an Incloſure ſo made, and ſo manured, Corn will grow, therefore this new Scheme is not univerſal: it will aſſiſt the old Methods of Huſbandry, but it will not ſupply their Place, and it is thus we recommend it to the Farmer: not as his only Practice, but as one that he ſhould underſtand as well as the others; one that deſerves to be uſed much more than it is; and that will often be of vaſt Service.

We ſee in this laſt Inſtance, that the Land cannot be brought into Heart by Tillage alone, even upon his own Confeſſion; this Sort of Land then muſt be brought into a Condition upon the Principles of the old Huſbandry; that is, by Clay, and the proper Manures, but it may be kept in Heart by Tillage.

In this Caſe the Method propoſed by Mr. TULL, has great Advantages attending it, tho' it will not ſucceed alone. This Land will be better kept in Heart by the new Tillage he propoſes, than by the old, becauſe the new is the more perfect. The Soil is made leſs fine in common Tillage, therefore the Advantage will be leſs; but in the Tillage he propoſes it will be more fine, and conſequently, the Effect will be greater.

We cannot ſee a greater Inſtance of the Effect of Huſbandry any Way, than by the Obſervation of ſuch a Piece of Land as this. The Farmer upon the Principles of the old Huſbandry, adds Clay to it, and by this Means converting it into Loam, he may be ſaid to make a Soil. When he has thus made it, it is in the Condition of one that is better by Nature, and it is now fitted for the new Improvement by a more perfect Tillage. It could not receive the Advantage of that Method according to the Confeſſion of its Author in its natural State; but it may in this improved Condition. We ſee therefore how uſeful it is to the Farmer to know every Practice, and not to ſtick to any one, but to employ them all as there may be Occaſion. 'Tis thus we propoſe them to him for his general Uſe. He ſees in this Inſtance he may make a Soil by the old Methods, and he may keep it in Heart by the new; ſo that the one ſhall continue to him thoſe Advantages he received from the other.

2

The two great Articles in providing that Plants ſhall have Nouriſhment, are, that the Roots may ſpread freely to their full Extent, and may every where have the due Preſſure in the Ground. Theſe are effected excellently by Tillage in a compleat Way, for the Earth is made fine and ſoft: it lets them in any where, and it cloſes every where about them. All the Earth is full of Nouriſhment for Plants, and their Roots are thus put into a Condition to ſeek for it, and receive it. If they could not ſpread by reaſon of the Hardneſs of the Ground, they muſt be content with what is ſupplied by the Earth juſt about them; and if they ſpread ever ſo freely, and paſs where there is ever ſo much Nouriſhment, they cannot get it unleſs they come to touch the Surfaces whereon it lies; and this they cannot do in half-tilled Ground, becauſe the Cavities are there ſo large, that the ſmall Roots paſs through them without touching their Sides. We repeat this upon the preſent Inſtance, that the Farmer may perfectly underſtand it, and remember it; for this is the Principle on which he is to act in the new Method of Tillage.

Let him be ſure therefore never to ſpare Tillage; the Land being poor is no Argument againſt his employing it: for the poorer the Land the eaſier it is wrought; ſo that there is leſs Expence in the Tillage; and if the Crop be not equal to that upon better Land, neither is the Rent.

The great Miſtake of our Farmers, is their not giving their Land ſufficient breaking; and in this they err very unhappily, for they go thro' the laborious and expenſive Part, which is that of the firſt Plowings; and they then leave off juſt when the Remainder is moſt wanted, and would be moſt eaſy as well as moſt advantageous.

They ſuppoſe the Soil to be fine enough when the Harrow will cover the Seed; as if the Covering of that were the only Uſe of the Fineneſs of Land. To give the Crop a due Benefit from the Land, every Lump of it ſhould be broke; for though the Seed may be buried among theſe, and covered in an irregular Manner, yet the Roots which ſhoot from it will never be able to penetrate thoſe Lumps, and they are of no Service to its Vegetation; whereas if the Tillage had been continued till theſe Lumps were broken, every Particle of the Soil would have been made uſeful; and the Crop would have had the Advantage of double, treble, or ſometimes much more Land in the ſame Field.

The Harrow is an Inſtrument that often miſleads the Farmer greatly to his Hurt. He ſuppoſes he can tear the Soil to Pieces with it; whereas, on the contrary, the Horſes that draw it frequently do much more Harm by their treading, than the Harrow does good. Let him never depend upon this Inſtrument for breaking the Ground; let him uſe it ſparingly and cautiouſly, and then it will be of Service; but much better Things than that will become hurtful upon improper Management.

The Roller may be mentioned as another Implement that often does Harm, though it may do a great deal of Good when properly uſed.

The

The Seaſon is all in all on this Head. The Buſineſs of Tillage we ſee is to break the Land, and divide its Parts; and this may be aſſiſted by the Roller, if uſed at a proper Seaſon, or otherwiſe it may be impaired by it. If the Roller be uſed in wet Weather, it preſſes down and cloſes the Soil inſtead of raiſing and opening it: but if uſed only in dry Seaſons, it breaks the Lumps, and does a great deal of Good.

We ſhall ſpeak of this more largely hereafter, but it was neceſſary to name it here where we are treating of the keeping the Ground in Heart by Tillage. If the Harrow be uſed firſt to tear up the Clods, then the Roller to break them, and the Ground be afterwards plowed again, and all this in dry Weather, no Kind of Tillage anſwers better, nor more tends to render the Earth fit for the ſucceeding Crop.

BOOK VI. PART III.

Of the Inſtruments of Huſbandry, and their ſeveral Uſes.

CHAP. XXII.
Of Plowing.

WE have explained in the preceeding Parts of this our Sixth Book, the Principles on which the Tillage of Land are founded, and the Means on which the Succeſs of that Treatment will depend. This may be called the Theory of Tillage; from which we now come to the Practice: nor would that Theory have been allowed ſo much Room in this Work, but that the Practice depends for its Succeſs entirely on the underſtanding it: and nothing is of ſo much Importance to the Farmer.

The Knowledge required for the Management of Graſs Grounds is comprized in a ſmall Compaſs, as will be ſhewn in its Place; and the Expence and the Hazard are both little. On the other hand, the Management of Arable Land is the Height of his Buſineſs. It requires the moſt Knowledge, and it demands the moſt Expence; therefore he is to endeavour by all Means to make himſelf a Maſter of it. The Profits ariſing from this Branch of his Profeſſion, if rightly managed, are much greater than from any other; but if he ſet about it ignorantly, the Loſs will be great alſo, and his Ruin may be the Conſequence.

All that has been hitherto ſaid is but preparatory to this Article; let him therefore apply the Knowledge he has acquired already, to the underſtanding this, and to the conducting himſelf in his Work according to that Underſtanding.

All Soils are not to be wrought in one Manner; if they were, the Knowledge of Huſbandry would be eaſy. But as each Kind has its particular and appropriated Manures, as has been ſeen already, ſo each Kind requires alſo its particular and appropriated Manner of Tillage. Plowing is the great or capital Operation of Huſbandry; and according to theſe Differences of Soils, and the particular Treatment they require, there have been invented different Sorts of Plows, which are ſeverally uſed according to the Nature of the Ground in different Places, and which ſhall be deſcribed in the ſucceeding Chapters.

There is great Difference between a tough Clay, and a light and looſe Sand: one of theſe Soils requires one and another Kind of Plow, and of plowing; neither would any uſe the ſame Inſtrument to till a deep Soil, and one where there is at five or ſix Inches Depth a Bed of Stone. There is often a Bed of barren earthy Matter alſo at this ſlight Depth, and this is not to be brought up with the Soil. All theſe, and a Number of other Particularities, demand their different Manners of plowing; and in order to its being rightly done, the Farmer is firſt to ſee there be a proper Inſtrument, and next to follow the Work with his Eye, that the Inſtrument be properly uſed: that the beſt Part of the Soil be not left untouched where it lies deep; nor the barren Part raiſed up where that lies ſhallow.

Theſe light and ſhallow Soils work eaſily, and coſt little in Tillage; but then they are often ſo poor, that they require a large Expence for Manures. Tillage alone, as we have ſaid, will make almoſt any Land bear Crops; but Manure is to be added to theſe, that the Crops may be great.

On the other hand, the firm and tougher Soils depend more upon Tillage than any Addition of Manure. In theſe, Plowing comes dear, but the Expence in the other Article is ſo much leſſened.

All that has been hitherto ſaid concerning Plowing, regards the Time before ſowing the Land; but we are to mention alſo under the Head of Plowing, another Species of Tillage, which is performed after the Plants appear; this is, properly ſpeaking, not Plowing, but Hoeing; though, according to the new Method of performing it by a Kind of Plow, and with the Aſſiſtance of Horſes, it has got the Name of Plowing. This is the Kind of Tillage called Horſe-hoeing Huſbandry, of which we ſhall give the Reader a full Account among the ſeveral other Methods. It has its Foundation upon very rational Principles; and its Succeſs anſwers accordingly: but there is a Backwardneſs of bringing it into Uſe, which ſeems to ariſe only from its Novelty. In other Countries where they are more ready than we to try Experiments, it is got into Uſe, and we can aſſure the ENGLISH Farmer with great Advantage. We hope therefore to ſee it ſoon introduced in the proper Soils, and under proper Circumſtances, here.

CHAP. XXIII.

Of the Form of the antient Plow.

WE may see in this Matter of the Plow, that the most useful Things are neglected, if they be common; and those who have it in their Power to be of greatest Service to the World, by considering and improving them, least regard them. There is no such Thing as an Author of any Note who has written on the Structure and useful Variations of this Instrument; nor have Men of Genius and Knowledge concerned themselves in the Fabrick of it. Ploughs seem to have been invented in the rudest Times; and, till very lately, to have had little Improvement. What has been done on this Head, however, by some ingenious Persons within these few Years, shews what is practicable; and we hope will lead others to the same useful Pursuit.

The first Kind of Tillage was probably with the Spade, and were that as convenient for large Quantities of Ground, as it is useful where it can be properly employed, no Instrument in the World could be compared to it. But when whole Fields came to be turned up and tilled, it was natural to devise some Method of saving the Labour of Men; and, consequently, the Plow, which may be called a Kind of Spade drawn by Horses, was invented.

As this was more and more frequently used, its Form became probably a little altered, but Improvements have been in nothing so slow: and this Instrument of such universal Use, and vast Advantage and Importance to Mankind, is still capable of many more; and it still wants them.

All Tillage we have shewn has its Advantage from dividing and breaking the Earth into a great many Parts. The Spade, as it is wrought by the Hand of the Workman, does this most perfectly; and it is for this Reason that Gardens are more fertile than Fields; but it may not be impossible, if proper Persons will set themselves about it, now that they know in what the greatest Perfection of Tillage consists, to make the Plow, by more Improvements, equal its Effect.

The Advantage of the Spade over the Plow is, that it goes deeper, and divides the Land into more Particles, and smaller: but the Plow, when its Structure shall be fully perfected, is certainly capable of this. The four coultered Plow is an excellent Contrivance, and shews that there is nothing impracticable in the Thought of forming a Plow that shall go deeper, and divide the Earth as much or more than the Spade.

The antient Plow, according to the best Accounts we have of it, had no Coulter, nor Earth Board, for the Share always going obliquely, served as an Earth Board; and the two Ears which were the Corners of a Piece of Wood lying under the Share, did the Office of Ground Wrests.

This Sort of Plow is used in Italy, and even in some Parts of France at this Time. It serves for the turning up of light Land, but it would do nothing with our stiff and tough Soils in many Counties.

This, so far as we know, was the first and original Plow, and it is a very plain and simple Contrivance. It did the Office for which it was intended, in the Place where it was invented; but it was not fit for other Lands, and other Countries, and therefore it was altered.

In those Parts of Italy where the Soil is perfectly soft and mellow, this Instrument does very well to keep it in Tillage; but even in these favourable Lands it is very unfit for the bringing them into this Condition; for when they have lain in Grass, and have any Thing of a Turf upon them, it is very difficult to manage them with it. They are obliged to go two or three Times over the Land before the Turf is all broken.

These Plows, for want of a Coulter to cut the Turf, tear it to Pieces with great Awkwardness and Difficulty, but when it is once cut through, the Soil being soft and tender, they easily get deeper.

As our Soil is very different from that of those Countries, our Plows are necessarily made different, for otherwise they could not cut it. The Necessity of a Coulter to ours is very plain, because of the Thickness to be cut, and that Necessity was doubtless the Mother of the Invention. Our Plows, when well made, cut off the Furrow at the Bottom flatwise, and therefore as it is as thick on the Land Side as on the Furrow Side: but the Plow cannot break it off from the whole Land at such a Thickness, so that there must be a Coulter to cut it off. By this Means the Furrow is turned perfectly whole, and no part of the Turf of it is broken. Hence if it lie long without new turning, the Grass from the Edges will spread, and form a new Turf or Sward on the other Side, which was the Bottom of the Furrow before turning, but is now become the Surface of the Earth.

If the Land be left thus, it will soon be greener with Grass than it was before plowing, and the Grass spreading its Roots, will bind it firmly and toughly together; so that there will require a great deal of Time and Labour to bring it into a Condition for the Service it is intended to answer.

This has shewn the Insufficiency of the common Plow, and from a Sense of this, has arisen the Invention of the four coultered Kind, to be described hereafter. Several others have been devised to answer the same Purpose, but none succeed so well.

CHAP. XXIV.

Of the several Kinds of Plows in common Use in England.

THE common Plow differs very much in Shape and Form in various Places; partly according to the Fancy of the People, and partly to the Nature of the Ground. Some have longer and some shorter Beams; and there

are great Varieties in the Length and Form of the Share, the Coulter, and the Handles.

In general, without regarding the Cuſtoms of particular Places, there is great Reaſon to have Reſpect to the Nature of the Soil on which it is to be uſed. Thus, in general, the Plow that is for ſtiff Clay ſhould be long, large, and broad, with a deep Head, and ſquare Earth Board, ſo that it may turn up a large Furrow. The Coulter ſhould be long, and very little bending, with a very large Wing; and the Foot long and broad, ſo as to make a deep Furrow. The Plow for moderate Soils ſhould be ſomewhat ſmaller than the former, but broad at the Breech: the Coulter ſhould be long and more bending, and the Share narrow, with a Wing coming up to arm and defend the Earth Board from wearing. The Plow for light Soils, ſuch as ſandy and the like, ſhould be lighter and ſmaller than any of theſe. The Coulter ſhould be more circular and thinner, and the Wing not ſo large.

This is a Direction contained in a ſmall Compaſs, yet it will give the Farmer the general Rule for his Conduct in this Reſpect: let him conſider his Soils under theſe three Heads of heavy, moderate, and light, and in this general Manner ſuit the Bulk and Fabrick of his Plow to them; and he will never make any great Errors.

Plows are ſometimes made with Wheels, and ſometimes without, but in general the Wheels are a very great Advantage; there are Circumſtances in which they are troubleſome, and therefore it is fit they ſhould be in ſome Plows omitted.

The Plow, which from its great Advantage above the others, might be eſteemed the firſt great Improvement in ENGLAND, is the Wheel Plow, that from the Place where it was firſt us'd has been long call'd the HERTFORDSHIRE Plow. This conſiſts of a Beam and Handle, a Neck, an Earth Board, a Sheath, a Share, a Coulter, a Pin, Pillow, and Wheels. Theſe are Parts exceeding familiar to the Farmer, but for the Sake of the Generality of Readers, who may not be acquainted with the practical Part of Huſbandry, they will be explained in the Figures, and we ſhall alſo ſhew how this Plow is form'd, as improved at preſent.

This HERTFORDSHIRE Plow, or common Wheel Plow, as it is uſually made, is very ſtrong, and is ſerviceable for moſt Uſes: it is very eaſily managed, it follows the Horſe lightly, and it ſuits almoſt every Kind of Land. The greateſt Exception to its Uſe is in miry Clay in Winter; becauſe the Wheels cut into them, and clog and ſtick when they are work'd at that Time of the Year. This is fit for that Sort of Ground when Summer Fallows are to be plow'd, and when a Graſs Ground is to be firſt turn'd up for Arable, for it turns the Turf very well, and is very fit for uneven Ground, and for the drieſt Summer Weather. Some make this Plow in the original Manner, with the Handle ſloping of one Side, but this renders it troubleſome to hold, or to follow; the Remedy was very eaſy, and People not bigotted to fooliſh Cuſtoms, have improved it greatly by making it ſtrait.

This is in a Manner the general Plow at this Time, and it is this varied more or leſs, but never much, according to the Pleaſure of the Owner, or Faſhion of the Place, that we ſhall always mean when we ſay the common Plow.

The ESSEX Plow, (for the beſt Way to diſtinguiſh theſe Inſtruments is according to the Places where they are uſed,) has its Earth Board, if the Expreſſion may be allowed, made of Iron; by this Means they make it rounding, and this has a great Advantage in the turning of the Turf, they generally make it light and fine, and the Wheels proportioned. It is in this Way very fit for light Soils, and rids a great deal of Buſineſs. We do not mean by calling this the ESSEX Plow, that they uſe no other in that County; but that is the Place where this Kind is moſt uſed, and ſeems to have been invented.

The LINCOLNSHIRE Plow owes its Invention and Form alſo to the general Nature of the Soil in that County. The Fen Land of that Place is, as we have before deſcribed under the Article of Soils, light, ſoft, and mellow, free from Stones, and naturally over-grown with Weeds and Sedge on the Surface; for this Land they uſe a Plow with a circular turning Coulter, and a large ſharp Share, this is often a Foot broad, and quite ſharp at the Edge. This Plow has no Wheels. There is a Foot at the fore Part of the Beam, which they ſet higher or lower with a Wedge, and by that Means they keep the fore Part of the Plow from growing deeper than they chuſe. And they have alſo Wedges for ſetting the hinder Part where the Handle joins the Beam. The Coulter ſtands in its uſual Place, before the Share, and is a round Iron Wheel, with a ſharp Edge, that turns upon an Axle as the Plow moves, and cuts through the Roots of the Sedge or Graſs as it goes round, while the broad Share cuts the Bottom. This would not do on other Land, but where the Soil is of this free and fine Kind, and is thus cover'd with a tough and tangled Matting of Roots, it anſwers the Purpoſe excellently.

The Dray or Drag Plow was at one Time, in a Manner, univerſal, and there is no particular Place where it can be ſaid to be moſt in uſe at this Time; for it is retain'd in ſome, and rejected in others, according to the Senſe and Spirit of the Farmers in adopting Improvements. It is a very plain and ſimple Kind; but notwithſtanding the Advantage the others have over it, on many Occaſions, this ſtill excells them all for wet Clays in the Winter Plowings; for having the leaſt Workmanſhip of any, it is the leaſt apt to clog, and having the feweſt Parts it is fitteſt for ſuch Ground, where nothing is requir'd but going on, and turning up. It is limitted to this Uſe, for on other Soils, and at other Seaſons, it is very much inferior to the other Kinds. This Plow has no Wheels, and it conſiſts of a Beam, Handle, Earth Board, and Share, and is ſet higher or lower, as they find Occaſion, by Wedges at the Sheath.

In SUSSEX they have a Plow with one Wheel, it is a very ill contrived, and very inconvenient Inſtrument. 'Tis broad in the Breech, and therefore it draws very heavily. It is a clumſy and ill-contrived Kind, that is growing out of Uſe there; and of all the Plows that have been invented, is the leaſt worth introducing any where elſe.

The

The largeſt Kind of Plow us'd in England, or perhaps in any Part of the World, is that which, in ſome Parts of the County of Cambridge, they uſe for cutting of Drains. This is of the Shape of the common Plow, and has no Wheels: it is very bulky in all its Parts, and has two Coulters; one of theſe is fix'd in the Beam as uſual, and the other in a Piece of Wood, faſtened to the Beam for that Purpoſe, theſe both turn inwards, and cut each Side of the Trench. The Share is very broad and flat, and cuts the Bottom of the Trench. The Earth Board is three Times as long as in other Plows, and caſts the Earth a great Way off the Trench. This Inſtrument cuts a Trench a Foot and half wide at the Top, a Foot at the Bottom, and a Foot deep. It is excellent for this Purpoſe on wet Lands, ſaving a great deal of the Expence of Work in the common Way of digging Trenches by Hand, but it requires a great Number of Horſes to draw it. There is ſomething in the Contrivance of this Plow, that may be uſeful farther than in the making of Trenches, and it is for that Reaſon propoſed here to the Farmer's Conſideration.

CHAP. XXV.

Of the Uſes of the common Plows, and their proper Make.

WHERE there is a hard and firm Soil; or where the Land is full of Flints, ſharp Stones, and Gravel, no Plow whatſoever does ſo well as the two wheel'd Kind, which may be ſuited to the Occaſion according to the Directions already given, with Reſpect to Strength: and where ſtrong Clays are to be wrought in Summer Fallows, no other Plow is equal to it. The Point of the common Plow will fly out every Step on theſe Occaſions, but this will anſwer very well when the Earth is ſo baked and hardened by the Sun, that no other will penetrate. The Wheels of this Plow ſhould be about twenty Inches in Diameter, and it will always run beſt if the Furrow Wheel be made a little larger than the other.

A great Advantage of this Plow alſo is, that it will work upon uneven Ground without levelling, ſo that none is equal to it for the plowing up of Paſtures where there are Molehills, and other Irregularities. Theſe diſturb the other Plow extreamly, even the leaſt of them, but this goes through all.

Although the ſingle Wheel Plow of Sussex be ſo clumſy and ill contrived an Implement, there is no Reaſon why the Uſe of a Plow with one Wheel ſhould be rejected. A very light and ſlender made Plow may be furniſhed with one Wheel inſtead of two, and it will anſwer excellently on light ſandy Soils. It will not be fit for harder Work, but running eaſily it will ſerve this Purpoſe better than any other.

The common two wheel'd Plow is to be drawn with Horſes or Oxen two a-breaſt. The heavy Plow without Wheels, which is uſeful for wet Clays, and other very heavy and diſagreeable Work is to be drawn by three, four, or five Horſes in Length. The great Uſe of this is where the Ground lies level, and where there are no Obſtructions of Roots, or the like, for theſe greatly diſturb its Operation. The two Wheel Plow is preferable in ſuch Caſes, notwithſtanding all its Inconveniences.

Whichever of theſe Plows the Huſbandman chuſes, let him take Care in the Make of it, that it be ſuited to the Soil upon which he is to uſe it. Let him ſee that it be made larger if it be for deep or ſtrong Soils; and lighter and ſmaller if for the light and ſhallow ones. When the Land is ſtiff and deep let the Coulter be long and ſtrong; in the deepeſt Soils the Coulter muſt go the deepeſt, becauſe the Weeds root deepeſt there.

Of whatever Form, or whatever Degree of Strength, let him ſee that the Iron Work be made true as well as ſound; for on the Exactneſs of this Part of the Inſtrument, depends the going of it true to the Pitch at which it is ſet, and its keeping to the Line wherein it is plac'd, without running out on one Side or the other.

As ſo much depends upon the Iron Work, it is a very prudent Method to have that made firſt, and wrought to a perfect Truth, and then to have the Wood Work made to it: for in the common Way of making the Iron to the Wood Work, the Smith is often forc'd to work wrong in order to ſuit it: in this Caſe no Art will make the Plow go well. Let him take Care that the Iron Work is wrought ſmooth, and rightly temper'd; and that it be kept bright and clean in the uſing.

The ſhorter and leſs the Plow the eaſier it is worked; but though this be a Recommendation in light Soils, there is no uſing of ſuch as have not a due Weight and Strength in tough and heavy Work.

CHAP. XXVI.

Of the Improvements of the common Plow.

THE Regard that has been ſhewn to Huſbandry of late Years, has occaſioned ſeveral Improvements of the Plow, for particular and alſo for general Purpoſes, and ſeveral new Forms and Kinds have been invented, ſome rather fanciful than advantageous, but others extreamly uſeful. There is no Part of Huſbandry in which more Improvement may be made, nor any in which it will be ſo immediately or certainly uſeful.

A double Plow has been invented ſome Years ago, and is at this Time in uſe in ſome Places, by which a double Quantity of Land is plowed at a Time, one Furrow by the Side of another. As this requires twice the Number of Horſes and of Men, the Expence is nearly equal to the Advantage: but this is a Hint capable of Improvement, for although in tough and deep Soils it loſes its Benefit, from the Neceſſity of a double Expence, yet certainly in ſome of thoſe light and ſhallow Lands we have in Buckinghamshire, and other Places, a double Plow might be ſo contriv'd,

triv'd, as to be drawn by two Horſes, and managed by one Man; and then certainly the Advantage would be double, and the Expence the ſame. This has never been put in Practice yet, but from what I have ſeen, I am very certain that it is practicable; and whoever ſhall bring it into Uſe, will be of great Service both to himſelf, and all that ſhall follow him.

There has alſo been a Contrivance of a Plow that turned up two Furrows at once one under another. This I have ſeen uſed, but it is ſo unwieldy, and difficult of Draught, that in its preſent Form it will never get into Reputation, nor is it fit for it; but we have ſeen already, what would be the Advantage of plowing deeper than ordinary, and that is enough to ſpirit up ſome who underſtand a little more of the Mechanic Arts to contrive one upon the ſame Plan with more Judgment. Doubtleſs it is poſſible to obtain this Advantage of deep plowing with much leſs Trouble than attends it in the Plow that has hitherto been contrived for that Uſe.

We have obſerved that the digging with the Spade is a much finer and more excellent Tillage than that with the Plow; and that the Reaſon why our Gardens are more fertile than Fields of the ſame Soil, and with the ſame Manure is, that the Spade digs deeper, and breaks the Particles of Earth finer. Now a Plow conſtructed upon this Plan, with better Judgment in the Fabrick of it, would have both thoſe Advantages: it would dig full as deep as the Spade, and might be made to break the Earth as much. It is ſurely worth the while of thoſe who have a Knowledge in the proper Arts, to devote ſome of their Studies to this Improvement of the Plow, which is doubtleſs the moſt uſeful Engine in the World; and at preſent very deficient, even in its moſt improved State. The adding Breadth to the Fin of the Dray or Foot Plow, will at all Times make it more and more ſerviceable in damp and ſtiff clayey Lands; and in plowing theſe the Horſes ſhould always go at Length, that they may tread leſs of the Ground: on the other hand, in light Soils, the Cattle, whether Horſes or Oxen, ſhould always go a-breaſt, for the double treading is ſerviceable to ſuch Land; in the ſame Manner with the treading of Sheep when they are folded upon it. In ſtony Ground that has Graſs of ſome ſtanding upon it, the Plow ſhould have a round pointed Share, with a Fin to cut the Roots of the Graſs, for the broad Fin is apt to jump out of the Ground.

In Ground that has been Wood, and has Roots remaining; or in other Places where there are a great many large Roots in the Way, it is a very good Method they uſe in ſome Parts of Staffordshire, of having an Inſtrument of Iron, with a ſharp Edge, ſet through the Beam of the Plow, behind the Coulter, and through the Plow-head. This, at the ſame Time that it arms the Plow for cutting theſe Roots aſunder, if rightly fix'd, ſtrengthens the whole Frame of it, and makes it able to bear the rough Work there often is in theſe Places, and which elſe would tear it to Pieces: in other Places thereabout, they uſe a Couple of ſharp Wings of Iron made faſt to the Plow-ſhare, which anſwers the ſame Purpoſe, but does not ſo ſtrengthen the Plow. Dr. Plot, in his Hiſtory of that Country, deſcribes theſe, and gives the Names of their Inventors: I find they are in Uſe ſtill, but not generally. Theſe may give Hints ſeverally, for there is not one of them but has its Uſe, nor one that may not be greatly improv'd.

But theſe are all of them Improvements, which rather ſhew what may be done, than execute it well in themſelves; they may be conſidered as Hints to what is proper, rather than as compleat Things: there remains one to be ſpoken of in which the Improvement is very great, and is carried to a due Degree of Perfection; ſo that the Farmer has no more to do than to order it to be made according to the Deſcription and Figure. This is the four coulter'd Plow, ſo highly and ſo juſtly extolled by the Author of the Horſehoeing Huſbandry.

CHAP. XXVII.

Of the Wheel Plow.

THE Foundation of this Inſtrument is the common two wheel'd Plow, in its moſt improved Condition, from which it differs in the having three additional Coulters; ſo that inſtead of one there are four. We ſhall here conſider this Wheel Plow in its moſt improved State; and in the ſucceeding Chapter deſcribe the four coulter'd Plow form'd upon it. This Plow conſiſts of two Parts, diſtinguiſh'd by the Names of the Plow-head and Plow-tail. The Head has two Wheels of about eighteen Inches Diameter, the Spindle or Axis of theſe is of Iron, and paſſes through a Box which ſtands croſswiſe of the Beam. This Spindle turns round both in the Box and in the Wheels. From this Box riſe two perpendicular Staves, called Crow Staves; theſe are faſtened into the Box, and have each two Rows of Holes, by Means of which the Beam of the Plow is raiſed or ſunk at Pleaſure, in order to increaſe or diminiſh the Depth of the Furrow. This is done by pinning higher or lower a croſs Piece, which is called the Pillow, becauſe the Plow Beam reſts upon it. At the Top of the two Crow Staves is another croſs Piece, called the Gallows. The Crow Staves paſs through this by Mortiſes, and are pinned into it. From the Box of the Plow within the Staves, there is carried a ſmall Frame compoſed of two Legs, and a croſs Top, to which the Links of Iron are fixed by which the Plow is drawn; this Frame is called the Wilds of the Plow. In the middle of the Box there alſo is a Hole into which is let one End of an Iron Chain, the other End whereof is faſten'd to the Middle of the Beam, this is called the Tow Chain, and faſtens the Head and Tail of the Plow together: at the End where it reaches the Beam, this has a Collar that goes round it, and is faſten'd by a Stake within Side the Box. This Stake is held up to the left Crow-ſtaff by a Wyth, which paſſes round it above, and under the End of the Gallows below: a Piece of Cord is ſometimes uſed inſtead of a Wyth: any Thing that may be tied will do. From the Top of this Stake goes an Iron Chain, called the Bridle Chain; this is faſten'd at one End to the Top of the Stake, and at the other to the Middle of the Beam of

the Plow, by a Pin in the ſame Place where the Collar of the Tow Chain paſſes round it.

This is the Structure of the Head of the Plow, and theſe are its ſeveral Parts.

The Tail conſiſts of the Beam, which is a ſtout and long Pole; through which, a little below the Pin that holds the Bridle Chain, and the Collar of the Tow Chain, there paſſes the Coulter, a long and ſlender Iron Inſtrument, which running downward and a little forward, ends near the Point of the Share. This Coulter is fixed in its Hole of the Beam by a Wedge, ſo that it can be raiſed or ſunk at Pleaſure; behind are two Handles, the one longer and the other ſhorter; the ſhorter of which meets the Head of the fore Sheat, where it enters the Beam, and is fix'd by a Pin, and faſten'd to the Top of the hinder Sheat by another Pin. Theſe Sheats are two Boards, the hinder one near the Extremity of the Beam; the other forwarder and more ſlanting, and are both faſten'd to the Share, which runs flat below. On the other Side of the Plow Tail deſcends another flat Board, called the Drock; to this the Groundwriſt is faſten'd, which is a Board running nearly parallel with the Share. The longer of the two Handles is alſo faſten'd to the Drock, and the Earth Board riſes at its Bottom. The fore Sheat is ſupported by a double Retch, which paſſes through the Beam, and is faſten'd by Screws and Nuts.

This is the four Wheel Plow as uſed at preſent in the Places where Agriculture is moſt underſtood, and beſt practiſed: we ſee it conſiſts of more Parts than the two wheeled Plow of HERTFORDSHIRE, according to the firſt Invention, but there is not one of theſe added Parts but is an Advantage in either Strength or Convenience.

CHAP. XXVIII.

Of the four coultered Plow.

WE have ſeen in the laſt Chapter the common Plow in its greateſt State of Perfection; that is, the two wheeled Plow formed upon the beſt Model, and in the moſt artful Manner that has been yet deviſed for it. We are in this Chapter to give an Account of that great Improvement upon it, which, as it adds Parts of the utmoſt Uſe, may very well be conſidered as a diſtinct Inſtrument, its three additional Coulters giving it a Power of breaking the Land beyond any other that ever has been invented to this Time.

The Reader, who by the Aſſiſtance of our Figures and Deſcriptions, has made himſelf acquainted with the Structure and Parts of the two wheel'd Plow, will find no Difficulty in comprehending this.

The Beam of the common two wheel Plow, is uſually eight Feet long; the proper Length of the Beam of the four coulter'd Plow, is ten Feet four Inches. The Beam of the common Kind is ſtrait all the Way, but that of the four coultered Plow riſes with a Bend when it comes toward the Wheels, to where it reſts upon the Pillow. The Beam, ſuppoſing the Plow to ſtand upon a level Surface, would be at the End of the Plow-tail only eleven Inches and a half from the Ground: at the Place where the Bend begins, which is a little before the firſt Coulter, it will be one Foot eight Inches and a half; and where the Beam bears upon the Pillow, two Foot ten Inches. This is the proper Make of the Beam of the four coulter'd Plow.

The four Coulters are thus diſpoſed, meaſuring from the Tail or extream End of the Beam behind. From this Extremity to the Back of the firſt Coulter, is three Foot two Inches; this Coulter has its Point near the Share: from the Back of the firſt, to the Back of the next Coulter, is thirteen Inches; from thence to the third thirteen Inches, and from thence to the fourth the ſame. So that from the End of the Beam behind, to the Place where it begins to bend upwards, which is a little before the fourth Coulter, counting from the Tail, is ſeven Foot. The Length of the additional Coulters; particularly of the fourth, or that next the Head of the Plow, would be a great Inconvenience in this Machine, but that is prevented by the bending of the Beam toward the Head. If the Beam were ſtrait as in other Plows, theſe Coulters muſt be very long to reach the Ground, and they would require to be very ſtrong not to bend, and this would make them expenſive and cumberſome; and at the ſame Time their Length, if ever ſo well form'd, would make them apt to looſen the Wedges wherewith they are fix'd in the Holes. This would make the Coulter riſe up out of its Work, but by this Contrivance of a crooked Beam, a moderate Length in the Coulters ſerve; they do not require any great Thickneſs or Quantity of Iron, and they always work with Regularity.

As to the Materials, the Beam may be made of Aſh or Oak, according to the Nature of the Ground whereon it is to be employed; for Aſh has the Advantage of being light, but the Oak is vaſtly ſtronger; ſo that when the Work will be very hard, the Oak in Spite of its Weight, is preferable. As to its Breadth and Thickneſs, they may alſo vary according to the Soil that is to be tilled; but for moderate Ground, the Beam at the firſt Coulter Hole ſhould be five Inches deep and four broad.

Giving this as a middling Proportion, the Size of the other Parts may be as follows. The fore Sheat, commonly called ſimply the Sheat, ſhould be ſeven Inches broad; the Retch upon it muſt be of Iron, and its left Leg muſt ſtand foremoſt, that the Edge of its forepart, which is flat, may ſit cloſe to the Wood of the Sheat. The Uſe of this Retch is to hold the Sheat up to the Beam, which it does by Means of Nuts and Screws. Through the top Part of the Sheat there is alſo to be a Hole, which is to be a ſmall Part within the Beam, ſo that a Pin being driven into the Hole, draws up the Sheat very cloſe to the Beam. The Elevation of this Sheat is a very great Article in the Management of every Wheel Plow. If this make an Angle of more than five and forty Degrees with the plain Surface whereon the Plow ſtands, that Inſtrument will never go well. In the four coulter Plow it ought

to make an Angle of forty-two or forty-three Degrees only.

This Sort of Expreſſion will be very well underſtood by thoſe who are uſed to Mechanics; but for the Sake of the common Farmer, we ſhall ſay all that is meant by it is, that the Sheat is to be a little leſs raiſed in this than it is in a well going common Wheel Plow.

The Length of the Share from the Point to the Tail, ſhould be three Foot nine Inches. The Fin of the Share riſing ſlanting from the Point upwards. The Point of the Share ſhould be three Inches and a half long, flat underneath, and round at the Top, and this ſhould be of hard Steel underneath. The Edges of the Fin alſo ſhould be well ſteeled, and its Length proportion'd to the Nature of the Ground.

Behind the Fin is placed the Socket, into which the Bottom of the Sheat, before deſcribed, enters; and from the Tail of the Share is to riſe a ſmall Plate of Iron, this is to be well rivetted to the Share: by this the Tail of the Share is faſtened to the hinder Sheat. This faſtening is done by an Iron Pin, with a Screw at the End, to which a Nut is to be ſcrewed on the inner Side of the Sheat.

The Socket is to be a Mortiſe of about a Foot long, at the upper Part two Inches deep; and the fore End muſt not be perpendicular, but made ſlanting, conformable to the fore Part of the Sheat that enters into it. The upper Edge of the fore Part of the Mortiſe muſt bear againſt the Sheat; and if it be not quite ſo ſlanting as the Sheat, a little of the Wood is to be pared off at the Edge to make it fit.

The upper Side of the Share ſhould be perfectly ſtrait, but its Neck on the under Side ſhould ſtand a little hollow from the Ground. This Hollowneſs ſhould be about half an Inch in a common Plow, but in the four coulter'd Plow it ſhould not be above a Quarter of an Inch. So that the Share, when it is firſt made ſtanding upon its Bottom, bears upon the level Surface only in three Places: theſe are the Point, the Tail, and the Corner of the Fin. The Hollowneſs of the Fin muſt be greater in a ſtony Soil than in others.

The placing of the Share rightly upon the Sheat, is the moſt important, and the moſt difficult Part of the Plowright's Trade: on this depends the well going of the Plow, and for this Reaſon; as it is more important in the four coulter'd Plow than in any other, we adviſe the Farmer when he has made himſelf a Maſter by theſe Figures and Deſcriptions of the Form and Structure of this Plow, to take Care that he employ a ſkilful and an honeſt Workman; and if he do not find the Plow go well when made, to look there for the Occaſion of the Fault, for in that part is generally the Seat of it.

The Groundwriſt is to be of Iron, its Length muſt be two Foot five Inches, its Breadth at the longeſt End four Inches, and it is to go ſomewhat ſmaller all the Way. Its Thickneſs in general is to be three eighths of an Inch; but at the ſmaller End it is to be much thinner, that it may be capable of bending ſo, that it can be brought cloſe to the Share.

At the ſmaller End of the Groundwriſt are to be four Holes, through one of which there goes a Nail that faſtens the Groundwriſt to the Sheat. This paſſes through a long Hole which is made in the Side of the Socket of the Share. The Space between the Outſide of the Groundwriſt, to the Outſide of the Share, is eleven Inches and a half, and this is the Width of the lower Part of the Plow-tail at the Ground: at the upper Side of the broad End of the Groundwriſt there are alſo ſeveral Holes by which it is nailed to the lower Part of the Drock, this is long, narrow, and has three Holes for the Reception of its Faſtenings.

The Earth Board has a riſing near its End, which takes hold of the End of the Sheat to faſten it the more firmly; and near that are two Holes by which it is fix'd to the Sheat; at the other End alſo there is a Hole by which it is faſten'd to the Drock.

The Pin which faſtens the Earth Board to the Drock, is to be thicker in the Middle than at the End, and this prevents the Earth Board from coming near the Drock. By Means of this Pin the Earth Board is alſo ſet at a greater or ſmaller Diſtance from the Drock, as there is Occaſion ſometimes to throw off the Furrow farther from the Plow than at others. It always ſtands a good deal farther out on the Right Hand than the Groundwriſt, and this is one Reaſon why the Drock is made crooked; bending outwards in that Part.

The long Handle of the Plow is to be five Foot four Inches in length, and four Inches broad in the wideſt Part. It is to have Holes in its lower Part for pinning it to the Sheat, and another near its upper End by which it is faſten'd to the Drock.

The Length of the ſhort Handle is three Foot nine Inches, and it is to have two Holes, both toward its lower End: by the upper Hole it is pinned to the hinder Sheat, and by the lower to the Top of the fore Sheat above the Beam of the Plow.

We come now to deſcribe the placing of the four Coulters in the Beam of this Plow, contrived for their Reception; this is the moſt important Article of all: and the greateſt Point to be obtained is, that the four imaginary Planes, deſcribed by the Edges of the four Coulters, as the Plow moves forwards, be all parallel or nearly ſo, for if this be not regarded, they will not enter the Ground together.

To make ſure of this important Point, the Holes for the Coulters muſt be made in the Beam of the Plow in the following Manner. The firſt Coulter is to be placed as already directed, the ſecond Coulter Hole is to be made two Inches and a half more on the Right Hand than the firſt: the third two Inches and a half more on the Right Hand than the ſecond; and the fourth two Inches and a half more on the Right Hand than the third. This will place the four Coulters conformable to the four Cuts they are to make in a ten Inch Furrow.

Now no Beam of a Plow is broad enough to hold theſe Holes in this Direction, and for that Reaſon a Piece of Wood is added to the Beam of the four coulter'd Plow to give Space for it. This Piece is to be very well faſten'd to the

Beam, and the ſecond Hole is to be made, as will be ſeen, according to the Diſtance, partly in the Piece, and partly in the Beam; and the others will be all made entirely in the Piece. The Piece is beſt faſten'd by three good Screws with their Nuts, and its Place is on the Right Side of the Beam. The Diſtance of each Hole to the Right of the laſt, muſt be meaſured from the Middle of one Hole to the Middle of the other.

The fore Part of every Hole muſt incline a little to the Left, ſo that the Backs of the Coulters may not bear againſt the Left Side of the Inciſions made by the Edges. Each Hole is to be a Mortiſe of an Inch and Quarter wide, with its two oppoſite Sides parallel from Top to Bottom. The Length at the Top is three Inches and a half, and at the Bottom three Inches: and the Back of each is not perpendicular but ſlanting, and makes the Coulter ſtand ſlanting. It is fixed in this Mortiſe by a Pole Wedge in the ſame Manner as the Coulter is in other Plows.

The Coulter is a Kind of Iron Knife, conſiſting of two Parts; a Handle, and Blade; the latter having an Edge. The Length of the Coulter is to be two Foot eight Inches, but it will ſhorten in wearing; the Blade is to be ſixteen Inches long, with its Edge running all the Way along it; the Handle is to be of the ſame Length. This is ſo long that it will at firſt very well ſtand up above the Beam, but it muſt be driven down lower and lower, as the Point ſhortens by wearing. The Handle is to be an Inch and ſeven-eighths broad, and ſeven-eighths of an Inch thick throughout.

The firſt Coulter in all Plows ſhould be ſo placed, that its Back ſhould bear againſt the Back of the Hole; its Right Side above to bear againſt the upper Edge of the Hole, and its Left Side to bear againſt the lower Edge: and for this Reaſon there always are required at leaſt three Wedges to hold a Coulter in its Place. The Pole Wedge ſtands before it, the other two, one on the Left Side above, and the other on the Right Side underneath: and the Hole muſt be ſo made, that the Coulter ſtanding thus acroſs it, its Point may incline two Inches and a half or more toward the Left than the Point of the Share if it were driven down as low as it: but it ſhould never be ſo low in any Plow whatſoever. As to its bearing forwards, the Point of the Coulter ſhould never be before the Middle of the Point of the Share. It muſt be ſet obliquely with Reſpect to the Share, as we have diſpoſed it in the Figure of the Wheel Plow, and it muſt never be ſet much more ſlanting; for if it ſhould, it would have greater Force to raiſe up the Pole Wedge, and would be continually getting looſe.

In the four coulter'd Plow, the three other Coulters are to ſtand in the ſame Poſture with this in Reſpect of the Inclination of their Points to the Left: this is a great Advantage to them; for by that Means when the Fin is raiſed up by turning the Handles toward the Left, their Points do not riſe out of the Ground on the Right Hand as they otherwiſe would. With Reſpect to their pointing forwards, Experience ſhews, that every one of the three ſhould be ſet a little more perpendicular than the next behind it; ſo that the fourth Coulter will ſtand neareſt to perpendicular of any of them.

None of theſe Coulters ought to deſcend ſo low as the Bottom of the Share, unleſs when the Plowing is very ſhallow. It is always ſufficient that they cut through the Turf, however deep the Plow go into the Ground.

When the Plowing is to be very ſhallow, the Fin of the Share ſhould be broad enough to cut off the fourth Piece of the Furrow.

The Nut which ſerves for faſtening the Piece to the Beam of the Plow, ſhould have two oppoſite Corners turned up, by which it may be driven round with a Hammer. This has ſo great a Force, that three of theſe will hold the Beam and the Piece as firmly together, as if they were one Bit of Wood. In dry Weather the Wood will ſhrink, and then the Nuts are to be driven farther on. The ſame Caution muſt be obſerved in other Parts of the Plow. Between the Nut and the Wood there ſhould be a thin Piece of Iron by way of Bolſter: this prevents the Nut from wearing into the Wood, it muſt be ſomething larger than the Nut, and of the Thickneſs of a Shilling. Some uſe a Piece of Leather, but when the Nut is to be often ſcrew'd, Iron is much better.

There muſt alſo be Iron Plates upon all the Coulter Holes both above and below. Theſe muſt be nailed on with Nails made for that Purpoſe.

Inſtead of a Collar moving round the Beam, 'tis much better to have a ſquare one with an open End, which ſhall faſten to it by a Couple of Crooks. Theſe muſt turn upwards, that they may not lay hold of any Thing that ſhall be turned up under the Plow; the Front or Cloſe-end of this Collar is to be a ſtrong Iron Bar, with ſeveral Notches. Two Pins are to be driven into the Beam of the Plow, juſt behind the ſecond Coulter Hole, one on each Side: and there is to be another Crook, called a (C) from its Shape, which is to go over the cloſe End of the Collar. Each End of this is a Hook, and one of theſe lays hold of the croſs Bar of the Collar, going into one of its Notches; and to the other is fixed a Link, which holds the Tow Chain to the Collar.

The Uſe of thoſe Notches, and this fix'd Poſition of the Collar is this; that as the Share wears at the Point, it always inclines a little to the Right; and this is remedy'd by removing the Crook into another Notch of the croſs Bar of the Collar, ſo that the Point of the Share is thus always kept in a proper Direction. The Length of each Side Bar of the Collar ſhould be a Foot.

We have ſhewn that the Tow Chain of the Plow is faſten'd within the Box by a Staff paſs'd through its firſt Link, as the Hook of the Collar holds its laſt. This Stake is commonly nailed to prevent its flying out of its Place. And when the Plow is to be drawn a little nearer the Crow Staves, the Method is to take in another Link of this Chain, paſſing through the Stake, and faſtening it as before: or it may be done better by taking hold of the Crook of the Collar, with a ſecond or third Link of the Chain.

This

This ſhortening of the Chain always draws the Point of the Share a little to the Left.

For drawing of the Plow there is faſten'd to the Box an Iron Machine, called the Wilds; this is very like the ſquare Collar, only its Legs are longer. The croſs Bar at the Top is notched as that of the ſquare Collar, but only one Leg of the Wilds is fixed to this ſquare Bar in the making; the other Leg is looſe, and has a Loop through which the other End of the croſs Bar is put, ſo that it is fixed on at Pleaſure. Both theſe Legs of the Wilds paſs through the Box of the Plow, and are faſten'd in behind it by a Couple of hooked Pins made for that Purpoſe. The Holes cut thro' the Box for letting theſe Legs paſs, are to be made ſlanting upwards, ſo that the fore Part of the Wilds may be higher than the hinder; otherwiſe the upper End of the Crow Staves will lean quite back when the Plow is drawn. The Uſe of the Notches in the Bar of the Wilds, is to give the Plow a broader or a narrower Furrow. A double Crook with a Link is fixed to this Bar, and by this the Horſes draw. If theſe Cattle are tall, the Traces muſt be long, elſe they will be apt to raiſe the Wheels off the Ground, and overturn the Plow.

The Legs of the Wilds ſhould be eight Inches and a half aſunder, and their Length nineteen Inches: the Links are to be ſix Inches and a half long. They are to be put into two Notches diſtant from one another, or elſe one Wheel of the Plow will advance before the other. When they are moved to the Notches on the Right Hand, it brings the Wheels toward the Left Hand, which gives the greater Furrow; and, on the contrary, when they are moved on the Notches on the Left Hand, it gives the Plow a leſs Furrow, by bringing the Wheels toward the Right.

The Height of the Wheels we have mention'd already, as alſo the proper Method of making one of them higher than the other: their Diſtance ſhould be two Foot five Inches and a half, as ſet from one another on the Ground. The Crow Staves ſhould be one Foot eleven Inches high from the Box of the Plow to the Gallows that goes acroſs them: theſe are to ſtand upright upon the Box, and they ſhould be ten Inches and a half aſunder.

The Pillow which croſſes the Staves below the Gallows, is to be pinned up at its End by two ſmall Iron Pins, and it is convenient to keep theſe chained to it, that if they chance to drop, they may not be loſt.

The Height from the Ground to the Hole in the Box where the Tow Chain paſſes through, is to be thirteen Inches. This brings it to two Inches below the Holes of the Wilds, on the hinder Side of the Box.

The Height of the Plow at the Place where the other End of the Tow Chain is faſten'd to the Beam, ſhould be twenty Inches from the level Ground; and about the Middle of the Tow Chain there ſhould be a Swivel, that one End of the Chain may turn without the other.

This is the Conſtruction of the four coulter'd Plow; and as it is founded upon the two wheeled Plow improved to the greateſt Perfection, the Parts of that Plow can never be ſo well underſtood as in the Deſcription here given for their perfect and exact Conſtruction. 'Tis therefore we have taken this Opportunity of entering into the full and exact Detail of them; and we have formed our Figures of them relatively thereto. It is very neceſſary that he who would undertake to make, or to give Orders for the making of a four coulter'd Plow, ſhould firſt thoroughly underſtand the Conſtruction, Parts, and Compoſition of a perfect one with a ſingle Coulter; and we have by this Means avoided the Repetition of a long and dry Detail of the Parts.

We have before ſhewn what was the firſt Conſtruction of the Wheel Plow, which was a vaſt Improvement upon the Inſtruments in Huſbandry of that Time; and we have here explained its farther Advances toward that Perfection, which it may be juſtly ſaid to have attained in the four coulter'd Kind.

When the four coulter'd Plow is made, let it be try'd with the ſingle Coulter before the others are put on. There may be a Fault in the Work that cannot be diſcover'd, even by a judicious Eye, till it is try'd; and this may prevent its going as it ought. That Plow which will not go well with one Coulter, certainly would not with four; but it would be very unjuſt to charge upon the Number of the Coulters, what is really the Fault of ſome Part of the Structure of the Inſtrument itſelf, independent of that Addition.

If the Plow goes well with one Coulter, then put in the other three; there is not much Fear but it will alſo go well with them. If it do not, then let the Poſition of the three additional Coulters be examin'd; and let it be ſeen in what that differs from the Rule, laid down here for that Purpoſe. That it differs in ſomething need not be doubted; for of a Certainty, if they be rightly diſpoſed according to theſe Directions, the Plow will go well.

To know whether a Plow goes well, examine the Furrow: if that be of an equal Depth on the Right Hand and on the Left; and if the Plow turns it off fairly, it is right. If in the going of the Plow, the Tail of the Share, and the Bottom of the Drock bear againſt the Bottom of the Furrow; and if it goes eaſy in the Hand of the Holder, without preſſing one Arm more than the other, the Farmer may be aſſured it is a good one. Such a Plow will go with four Coulters as well as one.

CHAP. XXIX.

Of the Management of a Plow in working.

WHEN the Farmer has got his Plow well made, let him ſee that he keep it in Order; and that he employ a Man in the working, who is able to manage it as he ought, and who has Honeſty enough to take the neceſſary Care and Pains. The Farmer depends more upon the Integrity and Knowledge of his Plowman, than on the Qualities of any other Servant whatſoever.

The Handles of the Plow being made of that Length

Length we have ordered in the laſt Chapter, are very uſeful for the proper guiding of that Inſtrument; but often the Plowman will cut them ſhorter to favour his Idleneſs. When they are ſhortened, he can bear his whole Weight upon them, and in a Manner ride inſtead of walking. If he ſhould play this idle Trick with long Handles, his Weight would tilt up the fore End of the Beam, and raiſe the Share out of the Ground. The keeping the Arms long therefore prevents this negligent Trick, and at the ſame Time gives him an Opportunity of managing the Plow to the greateſt Advantage.

An awkward Plowman will be continually over-ſetting the two wheeled Plow; but a careful Perſon who is uſed to the Management of it, hardly ever meets with ſuch an Accident. The great Danger of over-turning is, at the going out at the Land's End, from one Furrow to another. But the ſkilful Plowman lifts his Plow a little round, and then holds up the Crow Staves with the End of the Beam, by preſſing his Hand hard againſt the Handle, while the Plow lies down on one Side, till the Horſes, the Wheels, and the Body of the Plow come nearly to a Line in the Beginning of the Furrow; and then he lifts up the Plow and goes on.

Theſe little Contrivances are exceedingly uſeful. They are more eaſily ſeen in the Practice, than taught by Words; but what is here ſaid may ſerve to let the Farmer know when his Plowman manages his Buſineſs right, and when he does not; and may aſſiſt him in the giving one that is willing Directions.

In the four coultered Plow there is another Inconvenience very likely to happen, but very eaſily remedy'd: this is, that ſometimes the firſt or left Furrow is apt to come through betwixt the firſt Coulter and the Sheat, and in this Caſe it falls upon the Left Hand Side of the Plow.

This, though not of the Conſequence of many other Faults, yet is worth preventing, and the more as the Remedy is eaſy. To this Purpoſe let the ſecond Coulter ſtand a little higher than the third; and then the ſecond Furrow, holding the firſt at its Bottom, will carry it over together with itſelf, and throw it on the Right Side of the Earth Board.

Let me give the Farmer one Caution farther in this Matter; which is, that in this placing the Coulter, he never ſets it ſo high that it does not cut the Turf through. As to the firſt Coulter, though it ſhould cut but an Inch or two within the Ground, the Share will break off the firſt Furrow in raiſing it up.

If in the Plowing with this four coultered Kind, the Coulters become clogged and loaded with Pieces of the Turf, a Boy ſhould go by the Side with a forked Stick to clean them off from Time to Time, which is done very eaſily.

The Coulters being diſpoſed exactly as we have deſcribed, will have more Space between them above than below; ſo that this clogging will not happen often, and when it does, the Cleaning is eaſily performed. The Farmer may always know when he ſhall have Occaſion for a Boy to follow for this Purpoſe, becauſe it riſes not from the Fault of the Plow, but the Nature of the Ground. This Plow in clear Ground goes as free and clean as any, but when there is a great Quantity of Couch Graſs on the Land, its Roots hold the Turf together in ſuch a Manner, that it riſes in Pieces, and hangs between. This is the only Occaſion on which there is a Need of ſuch Aſſiſtance; but if it be not taken Care of, the Load of clogging Matter will fill the Spaces between the Coulters, and raiſe up the Plow out of its Work.

In the common two Wheel Plow there is a very great Inconvenience too frequent, and of very bad Conſequence; this is, the leaving a great Part of the Land unturned from the Shear's Point going too much to the Left. The Conſequence of this is, that the Work is done irregularly, and often a great Part of the Ground which is covered by the broken Earth, is whole and untouched, and the Weeds are found afterwards growing upon it. This is a great Fault: it defrauds the Farmer of ſo much of the Buſineſs he engaged ſhould be done; and there is nothing he ought to look into ſo carefully.

Sometimes he will find it happen from the Imperfection of the Plow itſelf, and then he is to apply to the Maker. The well going of a Plow principally depends in the placing of the Share rightly upon the Sheat; and in this Caſe the Remedy muſt be by an Amendment in that Article. This is the niceſt and moſt difficult Part of the Plowright's Buſineſs, and is what the Farmer is moſt concerned of all other to ſee done well: it matters not that the Maker can tell him, or ſhew him it is right as it ſtands upon the Ground, let him try it in ſome Work, and never be ſatisfied with it till it anſwers its Expectation.

This Fault laſt named, though it ſometimes be owing to the Make of the Plow, yet may alſo ariſe only from the Folly of the Plowman's ſetting it wrong: therefore this ſhould be tried firſt. His Fault is the ſetting it ſo that the Point of the Share turns too much to the Left: in this Caſe it will always cut croſly, and leave a Part of the Ground untouched, tho' covered by that which has been cut, and is thrown over it.

There is no Part of his Buſineſs which the Farmer is more under a Neceſſity of following with his own Eye than this. His Intereſt is engaged in the well executing of it, though the Servants is not. It is eaſy to plow too ſhallow, or too deep. Where there is a full Soil, the deeper the Plow cuts the better; but where the Soil is ſhallow, and the Bottom bad, let there be great Care taken that the Clay or whatever other bad Matter it be, ſhall not be turned up with the Soil. He ſhould himſelf overſee this that his Plowing may give him all the Advantage, and avoid all the Diſadvantage there is in the Condition and Nature of the Ground.

Some Choice is to be made in regard to the Situation, in the Manner, and Courſe of the Work. When a Land lies upon the Deſcent of a Hill, let it never be plowed ſtrait up and down, but croſswiſe. This has a double Advantage: for the Horſes are not tired, as they would be with going ſtrait up and down, and the Land alſo will fare a great deal the better.

These Grounds that lie upon the Sides of Hills are generally poorer than others, and they require a great deal of Manure, and that is soon washed away from them. We have observed in another Place, that the Reason of the Manure lasting but a little Time on such Lands is, that it is wash'd down by the Rains, together with the finest Part of their Mould, and runs to the low Grounds which are proportionably enrich'd as these are impoverished by this natural Cause.

Now as the Farmer would wish that these Grounds should retain all the Richness that he is able to give them, as well as all they have of their own, so far as that may be brought about by his Assistance, there is no Method by which he can better stop the Progress of this Mischief which exhausts them, or keep their rich Parts in them better than by this Method of Cross Plowing.

CHAP. XXX.

Of the Advantage of Plowing cross-wise on hilly Grounds.

WE shall see in this Article the Use and Necessity of the Husbandman's understanding the Reasons of what he is advis'd to do. He has been told that the Misfortune of all Lands lying upon a Descent is, that their rich Particles are dislodged by the Rains, and carry'd away with them. That this is the Fact is plain, for the Water runs off foul and thick. What makes it foul but the Matter it takes up from the Land? nothing else can, for it falls from the Clouds clear. We see that it carries off somewhat from the Land, and what should that be but the lightest and finest Part. This is what it can the most easily dislodge, or wash up out of the rest; and this is what it can hold up longest. This we know is the finest Part of the Soil, whether owing to Nature or to Art, and is what should supply the Plants with Nourishment. It is the lightest of the vegetable Mould, and the finest Part of the Manure.

The Time when this can be dislodged by the Rains most effectually, is when the Earth has been most lately plowed; and in the Method of plowing strait up and down, which is now very common in many Places, and especially where the Descent is small, what does the Farmer do but cut so many Trenches, for the giving it a clear and speedy Passage.

This is a terrible Fault. It must be his Business to stop and detain this Rain Water, which has taken up a great Part of the Riches of his Soil; but in this Way of working he assists its speedy running off. It is his Misfortune that the Rains have dislodged this fine Earth from among the rest, and yet he not only lets it go off with it freely, but in the very plowing of his Ground cuts it a Multitude of Passages. When the Rain has taken up this fine and valuable Part of the Soil, it must be his Business to stop and detain it as much as possible, because the longer it stays the more it settles, and leaves more of this fine Matter upon the Land.

We see what it is that is taken up by the Rains running down plowed Fields that have a Descent; let us examine what becomes of it. 'Tis wash'd out of the Field, and according to the Course of the Descent, and the Nature of the Fence, it runs to another Man's Ground, or to some other Ground of the Farmer's own which does not want it; or it stops in the Ditch of the Fence and there lodges, feeding an extravagant Abundance of Weeds, with what should have supported the Crop.

This is the Consequence of plowing strait up and down in hilly Grounds, which is yet practised in some Places, even in the most steep; and almost every where when the Descent is small. Where they have got into the better Methods of plowing cross-wise, it has been on Account of sparing the Labour of their Horses, more than with any other View: but we have shewn them here, and shall shew them more largely, that there is a much greater and more important Reason for cross-plowing in all Lands that have any Descent.

The Rains will fall equally upon the Ground, whatever be the Manner of dressing it, but their Effect will be very different according to that Method. Let us suppose an upland Field of a light Soil (for these are most hurt by this Effect of the Rains) plow'd cross-wise, and well wash'd by a Shower. What is the Consequence. The Water is thick and yellow, being full of the Richness of the Soil, and it is for running down according to its natural Course. It is stop'd at every Furrow. Very little of it gets out of the Field. And there is this double Advantage, that the whole Soil is better and more perfectly moistened by the Rain, than it could have been any other Way; and that the fine and rich Part which has been wash'd from the Surface, penetrating with the Water, becomes mix'd with every Part of the Mould.

This is an Advantage of the greatest Kind, and this singly, without any other Consideration, ought to influence the prudent Farmer never to plow any other Way than cross-wise, upon a Descent, whatever his Fathers have done before him in the same Ground; or whatever his Neighbours may be doing then upon Lands of a like Kind and Situation. Reason should get the better of Prejudice every where; though nothing should get the better of Experience. The Farmer must have seen in the Course of this Work, that Reason never contradicts Experience: indeed it is impossible it should: where the Fact is rightly stated, and the Reasoning is just, they always enforce and confirm one another.

CHAP. XXXI.

Of laying Land in Ridges.

WE have seen that a great Article in the rendering of Land fertile, is the breaking and dividing it into small Particles, whether this be done mechanically by the Plow, or by Fermentation given to it by Manures; that this breaking of the Soil into small Particles is essential

tial to the free Growth of Plants is very plain, becauſe it is from the ſmalleſt Particles of this Matter that they are nouriſhed, and the breaking of the Land in this Manner is the only Method of giving the Roots a free Paſſage between them, in their Search of this Nouriſhment.

On this, which is evident from the preceding Facts and Reaſonings, depends the famous Syſtem of Horſehoeing Huſbandry. But beſide theſe two Articles, of Liberty of ſpreading the Roots, and a proper Quantity of Nouriſhment, there are two other, without which Plants cannot thrive, theſe are a due Degree of Heat and Moiſture.

Corn, and the other common Produce of our plowed Land, demands a moderate Degree of each of theſe, and the Farmer is to guide his Practice throughout in ſuch Manner, as to give them a Supply without giving them Abundance. It will be aſk'd, can the Farmer cauſe Sunſhine, or can he call down Rain. Neither: nor do we expect Impoſſibilities of him, nothing is more eaſy than what we require him to do, and the Effect ſhews that it will ſucceed. We have ſhewn in our third Book, the Way by which he may defend his Lands from Cold by Fences, and in the Beginning of the preſent, in what Manner he may keep his Ground moiſt by Tillage, theſe Things therefore are in his Power; however little they may ſeem ſo to thoſe not acquainted with the Practices of Huſbandry, their Reaſons, and their Effects.

But as he is to communicate to his Crop all good, ſo far as he is able, ſo he is to defend it from all ill: and as in the preceeding Chapters we have ſhewn how he may give the Advantage, it remains that we ſhew how he may prevent the Hurt.

Now one of the greateſt Misfortunes that can attend a Crop, is too much Wet. This ſometimes happens from the Particularity of a Seaſon; but oftner from the Nature of the Land. When the firſt is the Caſe, the Farmer's Care muſt be to find Methods of carrying the Wet off; when the latter, he muſt employ all his Care to provide againſt it. Land that is too wet will never produce Corn well, and to prevent the Miſchief attending this Condition of the Ground, has been invented the Practice of which we treat in this Chapter, the laying Land in Ridges.

This is a particular Sort of Tillage, and its Effect is greater than thoſe ſeem to underſtand who employ it. They uſe it only to keep their Lands from being too wet, but it has an Effect in regard to the Degree of Heat, not leſs than with Reſpect to that of Moiſture.

We ſhall ſee, upon examining this Practice and its Effects, how well Nature has taught People to uſe it. We ſee them in the moderate Soils that are frequent in BUCKINGHAMSHIRE, and elſewhere, frequently lay four Ridges together: in KENT they often lay ſix, and the lower Parts of ESSEX eight, and in HUNTINGDONSHIRE, upon their wet and ſtiff Clays, they ſow all upon broad Lands, raiſing the Middle of the Ridges in ſome Places two Foot and a half higher than the Side Furrows. This at once expoſes thoſe tough and clammy Soils to the Sun better than any other Method, and drains them of the abundant Wet.

We have ſeen that Calcination by Fire reduces Clay to a good and rich Mould, and that the draining it of abundant Moiſture always abates its Toughneſs. Now theſe are the Effects of dreſſing ſuch Land in this Manner: and in order to have the full Effect of the Practice, let the Farmer take Care to make the Ridges run Eaſt and Weſt, where the Situation will allow it, becauſe in this Caſe the Sun gets at every Part of them the better; and in order to promote farther the other good Effect of draining, let him take Care always to keep the Furrows that are left, open and clean ſcowered. By this Means they will ſerve to carry off the abundant Moiſture; and to give it a free Diſcharge from the Ground, Drains muſt be made in the loweſt Places, that may run well into one another. This is ſo eſſential a Practice, that when the Plow will not make them deep enough, it ſhould be done by hand with the Spade; and the Earth that is taken out ſhould, in this Caſe, be carry'd to a Diſtance, that it may not be trampled in again.

The chief Deſign of laying Land in Ridges is draining of it, and making the Corn grow properly dry: but we ſee that by a proper Management it may be made to extend its Benefits farther. In this Caſe, of a clayey Soil laid in Ridges open to the Eaſt and Weſt, where the Situation is ſuch as to allow it without other Damage, the Sun acts in a double Way upon the Soil, not only giving it Warmth, when the abundant cold Moiſture is taken away, but by a gentle Calcination of the Surface, it reduces that ſuperficial Part to a State of greater Perfection, and to a Kind of Manure for the reſt.

We have ſeen that the Effect of the Sun and Air is a ſlow Calcination; that this does gradually what a Fire does haſtily, this has been ſhewn in its Effects on Shells, which whither they remain on the Sea Shore, or are ſcatter'd on Lands as a Manure, become, in time, white and brittle, and in all Reſpects reſemble ſuch as have been calcin'd in a Fire.

The natural Defects of many Lands, otherwiſe uſeful and good, are a too great Degree of Moiſture, and a Defect of Heat. The latter naturally ariſes from the former, for a Quantity of Water detained among Clay, or any other tough Earth, becomes cold, and chills the Plants that are laid upon it. The great Remedy, in this Caſe, is the laying the Land in Ridges; and that the careful Huſbandman may be ſure to know when this is requir'd, as well as how to do it, we ſhall give him the following Hints.

In many Places the Abundance of Moiſture, and the Coldneſs of the Soil, are very obvious to the Eye: the Land is clammy and wet the greateſt Part of the Year, and he will know of himſelf that this is not a Condition in which it will bear Crops to any Advantage. This obvious and plain Diſcovery of the Fault is moſt conſtant where the Occaſion of it lies high, where the Clay makes the whole Soil. But the ſame Fault may be in the Ground where the Occaſion of it lies ſomewhat deeper, and though it is not perceiv'd by the Eye, the Effects may be found the ſame. Thus when a Land has a thin, light, and looſe Soil at the Top, and a tough Clay at a ſmall

Depth under it, the Wet will run through the light Earth preſently; but it will lodge on the Clay underneath for a Continuance. This is a very deceitful Kind of Land. It will look dry, when it is, in reality, very wet below; and this in the very Place where the Roots find their Nouriſhment, for they do not ſpread much juſt at the Surface, but moſtly at ſome ſuch little Depth below.

As the other wet Lands ſhew themſelves to the Eye in their own Condition, the Fault of theſe is to be ſeen in the Growth of the Crop. When it is in a great Degree it diſcovers itſelf to the Senſes on every opening of the Ground, but even in a leſs it is capable of doing great Hurt, and it is then known by the Aſpect of the Corn or other Growths. If the Leaves look ſickly and yellow, if they droop, and the Stalk riſes ſlowly, we may be ſure this is the Fault of the Soil, and that it is owing to wet and cold: we may be certain that however dry and fair the Land may ſeem juſt on the Surface, it is wet at a ſmall Depth.

When the Cauſe of the Diſeaſe is known, the Remedy is eaſy, it is nothing more than this laying up the Land in Ridges. If the Deſcent of a Hill do not prevent, let theſe be open to the Sun, by being laid Eaſt and Weſt; and by this Means, while the Water is carry'd off by the Diſpoſition of the Ground, the Sun will calcine, and every Day improve the clayey Matter that lies on the Surface, from the Effect of plowing.

The Water naturally, in this Caſe, runs off the Ridges into the Furrows, and is thence, as before directed, to be carry'd by proper Drains out of the Land, to ſome River or other Conveyance.

CHAP. XXXII.

Of the wet Land on Hills.

WE have ſhewn that the very Intent of laying Land in Ridges, is to drain it of abundant Wet, the Conſequence of which is Cold: and as there are more Kind of Lands than one that are apt to be wet, and thoſe, according to their Differences of Condition and Situation, may require ſome Variation in the Manner of applying the Remedy, it will be uſeful to conſider them ſeparately.

The two principal Kinds of Land that are liable to be chill'd by Wet, are thoſe on Hills where there is a Bed of Clay under the Mould; and thoſe in level Grounds, which conſiſt of a very deep and very ſtiff Soil. The former Kind are to be treated of in this Chapter.

The Occaſion of the Miſchief in theſe is very obvious, the Rains fall upon this Ground, and ſoaking through the Mould, are detain'd by the Clay. They cannot enter the Clay, and therefore they ſpread themſelves among the Mould above; and the Mould below ſtopping it in its Deſcent, and more Water falling above, the whole approaches to the Nature of a Bog; the Ground being ſoft, pappy, and rais'd above the natural Level by the Water ſpread among it.

When this is the Caſe in a very great Degree, no Method of plowing can be ſufficiently effectual to remedy it. In this Caſe Trenches muſt be cut a-croſs with a Deſcent, to carry the Water off. And they may be fill'd up with rough Stones, and cover'd over with Earth again, ſo that all may be wrought as a level Surface: Reaſon points out this Remedy, but it is often too expenſive, and ſuch Lands, when too wet and too difficult of Remedy, are to be neglected: we therefore have named theſe only to ſhew, that they are not to be attempted by ridging; for nothing diſheartens a Huſbandman ſo much as undertaking what he afterwards finds cannot be done.

When the Wet is in a conſiderably large Degree, it may be diſcharg'd by laying the Land properly in Ridges, though not where it is thus very abundant: therefore let the Farmer firſt examine carefully whether the State of the Ground will or will not admit a Cure; if he thinks it will, this is the Manner in which he is to ſet about it.

Let him plow the Land in Ridges, almoſt croſs-wiſe of the Hill, but a little oblique or ſlanting: for if they be perfectly carry'd a-croſs, or quite ſtrait down, they will neither Way do. When they are thus carried croſs-wiſe, but a little diagonally, their parting Furrows lying open, will each ſerve as a Drain to the Ridge next below it: for when the Plow has made the Bottom of theſe nearly horizontal Furrows a few Inches deeper than the Surface of the Clay, the Water will naturally and ſecurely run to their Ends, without riſing into the Mould, provided no Part of the Furrows be lower than their Ends.

We have ſaid theſe parting Furrows and their Ridges, ſhould always be made a little obliquely; and this Obliquity or ſlanting ſhould be more or leſs, according to the Form and Declivity of the Hill.

We are to conſider that there are two Ways in which Water that falls upon an Hill runs off. The one is on the Surface, and the other is between the Mould that makes the Soil, and the Clay that makes the Bed under it. 'Tis this ſecond Courſe, or the running of the Water upon the Bed of Clay, and under the Mould, that we are to conſider on theſe Occaſions; for on that depends the Damage we propoſe to rectify. This is the Source of what we have directed, as to the Diſpoſition of the Ridges; and it will be found, on the moſt careful Examination, that as only this Method of ridging could keep that Part of the Soil dry, ſo there is no Direction in which they could run, that will ſo well ſecure the Advantage, as the carrying them with this Slant croſs-wiſe of the Hill.

In this Caſe the Conſideration of laying the Ridges Eaſt and Weſt, muſt give Way to this croſs Direction with reſpect to the Deſcent of the Hill. We have mentioned, under that Head, that there were Exceptions; this is the principal; and in this, as in all other Caſes, the greater Convenience is to be conſulted, and the leſſer is to give Place to it.

The Farmer who ſhall make himſelf perfect Maſter of his Buſineſs, will often find two Things would be right, both of which together are impracticable:

practicable: he muſt, in this Caſe, content himſelf with taking the beſt.

The Way of working on this Occaſion is to plow the Ridges in Paces, without throwing any Earth into the Trenches. In this Caſe the Ridges will be plain at the Top; and the Rain Water will ſpeedily run downward to the next Trench, and thence to the head Land, and ſo out of the Field.

Theſe are eaſy and plain Directions, and the Succeſs of them is certain; it not only is plain to Reaſon, but is vouched by Experience; and yet a great deal of Land that might be ſaved by it, is left to produce little or nothing by the common Treatment.

CHAP. XXXIII.

Of the wet Land that lies level.

THIS is the ſecond Kind of Land that is liable to be wet and cold, and that may be greatly mended by the Tillage in Ridges. Sometimes there are Springs on the Hills that add to the Quantity of Water which they have from Rains, and this makes the Cure more difficult: in theſe deep, wet, and ſtiff Soils that lie on a level, the Cauſe is always to be found in the Water that falls by Rain alone. But this will ſometimes put the Land into as bad a Condition as if there were Springs in many Places.

When a deep ſtiff Soil lies flat, and is plow'd ſometimes one Way, and ſometimes another by croſs Plowing, it will hold Water a long Time. By that Misfortune the Plow is kept out two or three Weeks longer than if it were in round Ridges. Sometimes its Flatneſs keeps it from drying till the Seaſon of Plowing and Sowing too are loſt.

The Farmers are backward in Plowing the hilly wet Grounds in Ridges, and more in this. They ſay it prevents the Benefit of croſs Plowing, which they count as a great Advantage, and they think they loſe a Part of their Ground by the open Furrows, which they otherwiſe fill up with Harrows. But theſe are Miſtakes and Prejudices, of which it becomes us to ſet the practical Farmer right; for on ſuch Notions which he receives upon Credit, without being at the Pains of examining whether they be true or falſe, depend the greateſt Part of his Diſappointments and Loſſes. Croſs Plowing is oftener a Hurt than a Benefit to Land: this is certain, and any one who is accuſtomed to Farming, and will examine what he from Time to Time ſees, inſtead of taking all Things upon Truſt, will find it ſo in Experience. This therefore is an Objection ariſing only from Prejudice in Favour of common Practice, and common Opinion: the other is entirely an Error; for, inſtead of loſing any Ground by Ridges, it is poſſible to gain ſome. In the moſt ſimple and common Practice none is loſt; and managing wiſely and properly, much may be gained.

Ground is gained for the Farmer's Purpoſe when its Surface is increaſed, and is capable of bearing more Corn; and this is plainly practicable in the Plowing in Ridges. If in this Cuſtom of Plowing we allow two Foot in ſixteen for an empty Furrow, ſtill the Difference of Surface between the reſt as it lay flat, and as it is plowed into Ridges, is much greater in his Favour than this Proportion is in Loſs of Quantity. All the Surface thus raiſed in Ridges is capable of bearing Corn, and therefore it is ſo much Ground gained to the Huſbandman.

This is the plain and abſolute Fact; and this is all that it concerns the Farmer to know. Many Arguments have been raiſed againſt it, but they are frivolous or falſe. We name them only that the Reader uſed to ſee Things thus canvaſſed, may not think we overlooked them. To the practical Huſbandman they are of no Importance, for they have no real Weight; and to the Curious it may be enough to ſay, that the Doctrine of the perpendicular Growth of Plants, on which all their Cavils are founded, is in itſelf erroneous and falſe.

It is certain the Surface of a Field meaſures more in Quantity when in Ridges than when flat; and it is equally certain that all its Surface, the empty Furrows excepted, is capable of bearing Corn. This is a ſhort State of the Caſe. Theſe empty Furrows have been taken into the Computation, and the Difference is in Favour of the Land in Ridges. No Sophiſtry can get the better of ſo plain a Fact; and it is upon this Fact, and the evident Advantage that wet and cold Lands receive from this Kind of Tillage, that we recommend to the Farmer the Tilling his ſtiff, cold, moiſt, and flat Lands, in this Method of plowing in Ridges.

The Succeſs and Quantity of a Crop does not depend upon the Space there is for the Corn to ſtand in, but on the Quantity of Earth there is for its Roots to ſpread in for getting of Nouriſhment: now we have ſhewn that the Roots of Corn ſpread near the Surface, or at a ſmall Depth under it; and we find from this alone, that the Increaſe of the Surface of Ground in meaſure, is in Reality an Increaſe of it in Quantity, ſo far as the Growth of theſe Plants, whoſe Roots ſpread at a ſmall Depth under the Surface, are concerned.

The Increaſe of Ground therefore is a certain and a conſiderable Advantage obtained from the plowing in Ridges, but it is not the only Benefit attending that Method. Beſide the great Purpoſe which is anſwer'd by it in keeping the Land warm and dry, the Ridges are a Shelter for one another, and a Defence againſt cold Winds; and when the Field has been exhauſted by frequent ſowing, the Ridges may be made juſt where the Furrows were, and there will be all the Advantage of freſh Ground.

Having explained the Benefits of Ridges, and the Reaſons on which they are ſupported, we ſhall proceed to give the practical Farmer two or three Cautions about the making of them, that he may be able to do what we have adviſed to the beſt Advantage.

In a deep Soil let the Ridges be made narrower, and in the ſhallower let them be broader. Let him overlook the Work, and have a particular Regard upon deſcending or ſlanting Grounds, to the Direction and Courſe of the Furrows; and if he intend to follow the Horſe-

hoeing Method, which we ſhall deſcribe hereafter, and which in a moderate and proper Uſe, has great Advantages, he ſhould rather chuſe a Land that is dry in its own Nature, than one that wants this Aſſiſtance of being laid up in Ridges, for they are often an Interruption to that Practice.

The Furrows are to be deep or ſhallow, according to the Depth or Shallowneſs of the Soil. When theſe Lands are improved by this Method of laying them in Ridges, Wheat and Rye need not be ſown upon them ſo early as they are in their cold and wet natural State; but they muſt ſtill, with all this Improvement, be ſown earlier on them than on Lands that are naturally dry, and warm. For Summer Corn, on the contrary, the cold Land muſt be ſown laſt.

In many of the Weſtern Counties they ſow all their Barley with a broad Caſt upon broad Ridges; and in KENT and ESSEX they frequently ſow it on narrow Ridges like Wheat: in this Caſe there are to be two ſmall Harrows uſed, one of which is to take each Side of the Ridge, and this Method is then very ſucceſsful. They roll it with a Roller of a particular Structure, called a Belly Roll, that goes between the Ridges.

CHAP. XXXIV.

Of the Advantage of Tillage by the four coulter'd Plow.

WE have deſcribed in a preceding Chapter, the Make and Conſtruction of that excellent Inſtrument, the four coulter'd Plow, in ſo preciſe and punctual a Manner, that the careful Reader, altho' he have never ſeen one, cannot be at a Loſs to order the making of it; and having now treated ſo far of the Nature and Advantages of Plowing in general, we ſhall be underſtood with Eaſe in recounting the Benefits that attend this particular Method.

Nothing gives the Huſbandman more Trouble than the conquering a ſtrong Turf; and there is no Method whatſoever by which he can effect this ſo well, as by the four coulter'd Plow. The richeſt Land is ſubject moſt of all to this tough Head; and the deeper the Soil, the larger muſt neceſſarily be the Furrows; for if they be too ſmall, a great Part of the Mould will be left unmoved, and ſo loſt to the preſent Uſe of the Farmer. A narrow Furrow cannot be plowed deep, becauſe the Plow will continually ſlip out from the hard Land toward the Right Hand, unleſs the riſing Furrow be of ſufficient Weight to preſs the Plow toward the Left, and keep it in the Work. The deeper the Farmer goes, the greater Weight is required to preſs the Plow: ſo that the deeper the Land is into the larger Furrows it muſt be plow'd. If the Work be done with a common Plow of the very beſt Invention, for a Plow with one Coulter is not capable of doing it otherwiſe. The Conſequence of this is, that in a very ſtrong Land that has reſted ſome Time, it is the Work of many Years to get into a good Tilth. This the Farmer who has had Land in ſuch Condition upon his Hands, has never failed to find to his great Trouble, and his Heart will go with me as he reads this Account. The Price of this laborious and repeated Tillage often comes ſo high, that it reduces the Profit of rich Land below that of poor.

It is a common Pretence among the Plowmen, that when they have ſlightly, and imperfectly broke up a Land at the firſt Plowing, they will go deeper, and do it better the ſecond; but they know they promiſe what cannot be performed. It is of the utmoſt Importance to the Farmer to cut and divide ſuch Ground in the moſt perfect Manner; we ſee that the common Plow cannot do it well, and ſeldom does it otherwiſe than by halves; nor is there any other Remedy that is not too expenſive for the poſſible Profit. For this Reaſon the four coulter'd Plow is propoſed to him moſt of all Things on this Occaſion. It is an Inſtrument uſeful on many others, but it was invented for this, and will not fail to anſwer to his perfect Satisfaction. This Land muſt not be plowed a ſecond Time in wet Weather, for that will make the Weeds grow; and if it be done in dry, the Plow will never go deeper than it did at firſt.

Therefore the common Method of Tillage does not anſwer to any tolerable Advantage on ſuch Land. The Farmer ſees this, but he knows not how to help himſelf. If he attempts it by the Breaſt Plow, the Work is very expenſive; and if there be many Stones in the Soil, as is often the Caſe in theſe Lands, it is altogether impracticable. If the Turf be pared off very thin with a Breaſt Plow, and laid to rot before it be plowed in, in the common Way, this may do; but if the Seaſon be wet, it will grow inſtead of rotting; ſo that in moſt Caſes this is a very hazardous Undertaking, and in many it is not at all practicable.

Even digging up the Turf with Spades would not anſwer in this Ground, unleſs it were done extreamly thin, which will never be procured to be faithfully executed at any Expence. As the Spring is uſually wet, there is Danger in cutting up the Turf for rotting any Way at that Time, for Fear of its growing; and if it be deferred till Summer, the Plowing afterwards in dry Weather on ſuch a Soil will be very inconvenient, and the Wheat Seaſon probably loſt.

In theſe Exigencies which happen very frequently, and moſt of all upon the richeſt Land; if the Farmer will venture upon the Breaſt Plow, or that ſlight Plowing which only cuts off the Turf, let him do it not in the common Way, by the Force of a Man's Breaſt and Arms puſhing the Plow before him; but let him have Recourſe to that particular Kind of Plow, which we have directed to be made for the cutting up the Turf for Burnbaiting, and the Roller deſcribed with it. Theſe two Inſtruments will give him an Opportunity of getting up the Turf, and of cutting it to Pieces in a much more eaſy and expeditious Method than the common Way; but yet this is by no Means comparable to the doing it at once by the four coultered Plow.

In the common Way of Plowing, this Kind of Land cannot be cut in Furrows of leſs than ten Inches broad; and to this is owing all the Diſad-

Diſadvantage: to this it is owing that the Land is ſeveral Years before it can be ſufficiently broke and divided, and that the Graſs and Weeds grow with the Corn. But with the four coulter'd Plow this ten Inch Furrow is cut into four equal Parts, ſo that there is no Part above two Inches and a half broad, and this is done thoroughly; for the Coulters cut thus to the whole Depth of the Soil, tho' it be fifteen or ſixteen Inches.

What a prodigious Advantage! and it is done as eaſy as by the common Method of Plowing: for before the Furrow is raiſed by the Share, it lies faſt, and makes an equal Reſiſtance againſt all the Coulters, ſo that they all pierce quite through it.

The dividing the Furrows length-wiſe into four Parts, is not all the Advantage that is gained by working it with the four coultered Plow. This would in a Manner make one plowing anſwer the Purpoſe of four good ones: but beſide this, it is a natural Conſequence that the Furrow is divided croſs-wiſe; for the Ground-wriſt in this Method preſſes and breaks the Right Hand Quarter; and the other three Quarters, as they muſt neceſſarily bend in coming over the Earth Board, break alſo in falling into many ſmall Pieces.

Nothing of this happens in the working by the common Plow, where the Furrow being of ſuch a Thickneſs as very well to keep entire; when the Soil is any thing ſtrong, falls whole. Counting therefore the firſt Diviſion made by the Coulters, and the ſecond by the natural and neceſſary breaking, there is no Queſtion but the four coulter'd Plow does at once Plowing, divide the Soil more than twenty Times as much as the common Plow. It has therefore twenty Times the Uſe; and it does the Farmer twenty Times the Service: we ſee it is very eaſily practicable, and he who ſhall try it will find, that far from our making the moſt of what it will do, very frequently the Advantage is much greater. Frequently when the Earth is of a right Temper, neither too dry nor too wet, the Earth Board in turning the Furrows off will crumble them to Pieces: they ſhall fall into a Kind of Duſt, and hardly ſuch a Thing as a Lump of any Size will remain in the Field.

We have ſhewn already in the firſt Part of this Book, that the breaking and dividing the Earth into ſmall Particles, is the great Thing in which the Benefit of Tillage conſiſts; and it is very evident from the Effects of this Way of Tilling, that one or two common ſlight Plowings after this one Plowing with the four coultered Kind, will reduce the whole Soil in a Manner to Duſt. The whole Depth of the Soil is directly brought into Tilth; and the Turf being cut into theſe ſmall Pieces, rots and decays preſently, adding a Kind of Manure to the Richneſs given by this breaking of the Soil.

The greateſt Uſe of this Plow is in the conquering and reducing a ſtrong Turf; this ſcarce any other Inſtrument of Huſbandry will do without a great deal of Time, whereas the preſent does it at once. When the Turf is cut up large, as it muſt be by the common Plow, the Pieces lie hollow, and as the Air can come to them, they grow; but being cut into ſuch ſmall Pieces by this Plow, they lie cloſe and rot, becauſe they have not Air for growing. The Length of the Roots is alſo a great Diſadvantage in the common Way of Plowing; for they will ſhoot from the Joints, when they are of any good Length, as that Sort of Tillage always leaves them: but in the Uſe of the four coultered Plow, they are not only torn up, but cut to Pieces; and thoſe ſo ſhort, that if they are buried they rot; and if expoſed on the Surface, they ſhrivel and wither, ſo that either Way they periſh.

Any Weather will do for plowing with this Inſtrument, in which a Plow can be uſed, but in general wet is beſt; it may be uſed when the Ground is ever ſo moiſt, provided the Horſes are not mir'd in drawing it: and there is no Way in bringing Land into Tilth in ſo ſhort a Time, or with ſo little Expence as by the Uſe of it. No Farmer ought to be without a Plow of this Kind, who would be ſure that his Land ſhall never be out of Tilth.

As we have mentioned the great Advantages of this Inſtrument, we ſhall name alſo its Inconveniencies, for it is not without theſe, tho' they are nothing in Compariſon of the other. The four Coulter Plow is harder to draw than the common Wheel Plow, and its Beam being longer it lies farther behind, and comes heavier after the Horſes; its whole Weight alſo, the Strength and Thickneſs of the ſeveral Parts being proportion'd to the Length, is conſiderably greater than that of the common Plow.

For this Reaſon it will always be proper to add one Horſe to the uſual Number for the drawing of this Plow; or if a ſtronger Team be employed, the Difference will not be ſo much felt. We give the Farmer this Advice that he may know what he has to do, and ſet out right; but it would be idle to name it as a Counter-balance to thoſe great Advantages which we have ſhewn attend the Uſe of this Inſtrument.

The Difference from the Weight of this Plow, and the Length of the Beam, is not ſo great but that it is near as eaſily drawn in moiſt Weather, as the common Plow is in dry Weather on the ſame Ground, and at the ſame Depth. Indeed one great Reaſon of its following heavily is the Depth to which it cuts; and this is ſo great a Benefit, that it would be very idle in the Farmer to grudge the adding one Horſe to his Team for obtaining it: the four Coulter Plow will, upon Occaſion, cut two Spit deep, as before obſerved, which is a prodigious Advantage; but when this is not required, it will cut as ſhallow as any other Kind, and then the Weight is very little felt.

The cutting the Furrow into four Parts, is ſomething, for adding to the pull of the Horſes, but it is not much. When the Ground is in a right Condition, and the Coulters are in good Order, they cut thro' very eaſily; and the Furrows being thus divided, riſe ſo much the more freely upon the Share and Earth Board, than they would do if whole; that perhaps as much is gained in the Eaſe of working this Way, as is loſt the other.

Plows with two Coulters inſtead of one have been uſed in different Places, and always with

the greateſt Succeſs; the adding a third and a fourth Coulter, muſt of Neceſſity increaſe the Advantage; and upon the Rules, Deſcriptions, and Figures we have given of the ſeveral Parts, and the putting them together into one whole and regular Inſtrument, we hope the Farmer will not fail of having it done to his Satisfaction. The Difficulty is not great, but the People who make Plows are very ignorant; nothing could have brought the Plow with two Coulters into Diſuſe, but the bad Way of making it: and nothing but the properly putting together this new Kind can be wanting to the bringing it into general Favour.

CHAP. XXXV.

Of the general Benefits and Advantages of Plowing.

WE have conſidered Plowing as the capital Operation of the Huſbandman's Profeſſion, and we have therefore treated it very much at large with Reſpect to the Structure and Make of the Inſtruments of that Name, and Methods of uſing them on particular Occaſions: now that we may leave no uſeful Part of that Operation neglected, we ſhall in this concluding Chapter on that Article, lay down whatſoever of general Matter it may be fit that the practical Huſbandman retain in his Memory.

The plowing of Fallows is a great Advantage to them; this is the Senſe of all Mankind, and Tenants are bound by Articles to perform it at certain ſtated Periods for the Benefit of the Landlord. What is thus required by the Owner, will be alſo, at proper Seaſons, a Benefit to the Perſon who rents the Ground; and in general the Farmer may be aſſured of this, that the Expence he employs in Plowing, will bring him in many Times the Sum in the Produce. The old Authors could ſay univerſally, that the Advantage of Fallowing conſiſted in two Things; which were the expoſing the Soil more to the Sun and Air by turning it up in Ridges, and the breaking the Lumps and Clots of Earth by frequent ſtirring and turning. This is the old Doctrine, it is found in theſe Words in Markham, and that innumerable Set of Writers who have copied from him. This is the Principle upon which the Horſehoeing Huſbandry is eſtabliſhed: therefore it is idle to rail at it, or to conſider it as a new Doctrine.

Mr. Tull was a Perſon of great Induſtry and great Sagacity. He read carefully what was written on Huſbandry, and he adopted the beſt Things; and improved upon them. His Syſtem is new, but the Foundation of it is, as we have ſhewn, in all Reſpects as old as any Thing we know of Huſbandry. It is unjuſt to accuſe it of Novelty and Whim, the Principles on which it is eſtabliſhed are old and true.

The plowing of Fallows, beſide breaking and expoſing the Ground to the Seaſons, kills the Weeds; turning up their Roots to be wither'd by the Air, and overſetting the Seed Shoots before they are of ſuch Growth as to exhauſt the Land.

A great Caution the Farmer is to take is this, that he harrows no more down in Winter than he ſhall quickly be able to raiſe up again in Ridges; for if it get wet by Rain while it lies flat it will grow poachy, and very difficult of plowing afterwards. This is the Caſe moſt of all in wet Lands, and theſe frequently breed ſuch Quantity of Weeds upon it, that they exhauſt a great deal of Nouriſhment while it is expected to be recruiting. The beſt Way is to harrow only in an Afternoon, and to harrow no more than is to be plowed next Morning; or to harrow early in the Morning, what is to be plowed in a few Hours afterwards.

If the preceding Summer have been wet, the Land will naturally be full of Weeds: in this Caſe let the Farmer plow it up early in Winter to kill this uſeleſs Growth, and to mellow the Soil.

The antient Writers ſpeak of a Plow that was managed by one Man only, who could very well both guide and drive. Such a Kind may be made upon the one wheeled Plan; it may be light and ſmall, a ſingle Horſe may draw it, and a ſingle Perſon very well manage it: but this tho' pretty and familiar, will be of a limited Uſe, for it is fit only for a light and well wrought Soil, and is to be uſed only in ſowing Time. Such a one, however, it may very well be worth the Farmer's while to have when he has ſuch Land, for in thoſe Fields in a moiſt Seaſon, it will anſwer excellently.

They uſe at this Time in ſome Parts of the Weſt of England, a Plow that has neither Wheel nor Foot. It is made upon the Principle delivered in Mr. Blith's Huſbandry, but it does not anſwer quite ſo well as he ſeemed to think it would. The Uſe of it is confined to eaſy Ground that is even, for where there are Roots or Irregularities, it does very poorly.

We name all theſe Particulars that the Farmer may take his Choice among them, ſuiting the Kind to the Uſe; for we have ſhewn him the Uſes and Diſadvantages of all the Sorts. Theſe two laſt we have named in this Place, becauſe tho' good in particular Places, and on particular Occaſions, they are not to be rely'd upon in the general Practice.

There have been Propoſals by Dr. Plot and others, for digging Ground for Corn with the Spade as we do for Flowers, and managing a Field as we do a Garden. There is no Doubt of the Succeſs of this, but the Expence muſt be monſtrouſly great; and by the Methods already directed, and to be added when we come to the Article of Hoeing, according to the new Method, the ſame Advantage may be obtained with more Eaſe, and at leſs Expence.

There is alſo another Method to be named on this Occaſion, in which the Plow and Spade are employ'd together, this is called Plow-trenching. It is uſed in deep and light Land. One Furrow is plow'd, and half a Dozen Labourers following at proper Diſtances one from another with Spades, are to dig in the Furrow, and throw up the Earth on the Glebe turned by the Plow. While the Diggers are at this Employment,

ployment, the Plow is to turn up another Furrow at a reaſonable Diſtance; after which the Labourers are to do the ſame there, while the Plow is turning the upper Earth of another Furrow into the former Trench.

The Principle upon which this Practice is founded is very right, but the Method wherein it is done is in the higheſt Degree aukward. We have named it that the Reader may know what Plow-trenching means; but we have delivered Methods of anſwering the ſame Purpoſe in ſo much eaſier a Manner, and at ſo much ſmaller an Expence, that this will never be found worth any Perſons while to think upon.

CHAP. XXXVI.

Of the Beneſit of converting Paſture into Arable Land, and of continued plowing.

WE have mentioned occaſionally before, the Propriety there may be in changing Paſture into Arable Land, in order to keep up the Proportion of the two: but this is not the only Thing that may lead to ſuch Practice. Paſtures on certain Soils are very apt to ſpoil of themſelves, and that often when they are rich as well as when they are poor.

The Growth of Moſs is a great Enemy to good Paſturage, and frequently Lands are ſo over-run by it, as to be in a Manner ſpoil'd for Graſs. In this Caſe, if the Methods we have laid down in treating of Manures prove inſufficient for the killing this pernicious Matter, the Farmer muſt, at all Adventures, have Recourſe to plowing. That always ſucceeds, and there is no Way of deſtroying Moſs like it. After a few Crops this Land may be laid down for Graſs again, and will ſucceed excellently.

In all barren and neglected Land, plowing is the great and immediate Method of Improvement. The breaking and dividing of the Soil give it Fertility, as has been ſeen already, and at the ſame Time it kills the Weeds, that never fail to grow in Abundance on ſuch Places, by tearing up and expoſing their Roots.

Sometimes it will happen that a wet Summer will fill a Land with Weeds after what was intended for the laſt plowing in the Fallow, by which it was preparing for Barley; in this Caſe it muſt have another ſtirring during the Winter, in order to kill them. Some content themſelves, in this Caſe, to tear them up with a Harrow; but plowing is much better, and it is then to be laid up high, that it may keep dry the Remainder of the Seaſon, and by the Effects of the Froſts and Air after this, it will be excellently prepar'd for the Seed Time in Spring.

The common Method of Farming is at preſent by the Uſe of Tillage and Manures jointly, and it comes at a very moderate Expence. Suppoſing the Land to be out of Heart, and to take in the whole ordinary Compaſs of the Buſineſs it is this. In APRIL, to begin the Account no ſooner, they lay on twenty Load of Dung to an Acre, this coſts about a Shilling a Load; the Ground being already in Tillage, there will require beſide the Dunging, two Plowings to prepare it for Wheat. Each of theſe Plowings will be about four Shillings an Acre Expence, the Land will be then ready for Wheat in the Beginning of OCTOBER; the Seed will coſt about five Shillings a Buſhel, and about two Buſhels will be requir'd to an Acre: the weeding, reaping, and binding, will afterwards coſt about five Shillings an Acre more: and the inning of the Harveſt, and repair of Fences, may be ſet at about ſix Shillings an Acre: the Price of thraſhing is according to the Richneſs of the Crop, for the Labourer is paid by the Buſhel. Here is all the Expence, and all the Trouble, and the Harveſt, at a moderate Computation, yields thirty Buſhels of Wheat an Acre.

After this, without the freſh Expence of dunging, the Land will very well bear two Crops more, one of Barley, and another of Peaſe, or the like.

Theſe Crops are of leſs Value, but then they come at a leſs Expence. Barley is mowed inſtead of reaping, ſo that the great Charge in that Article is ſav'd; and Peaſe being cheaper in the Seed, and requiring to have the Ground but once plowed, come more reaſonably yet.

Seven Shillings an Acre is ſav'd in the Crop of Barley, and thirteen Shillings in that of the Peaſe, not counting the ſaving of Dung, ſo that the Charge of theſe Crops is much leſs than that of the Wheat, as well as the Price in the Produce.

This is all that the Country Farmer in general knows of the Buſineſs of Huſbandry, and thus he practiſes it. Yet even this Way the Practice is ſuch, that he can live and lay up ſome Money. The Expence of an Acre of Ground for the three Crops, taking in every Article, is about five Pounds, thirteen Shillings, reckoning at the higheſt; and the Produce of the three, computing in the moſt moderate Way, is about eight Pounds.

This Account may tempt any one to look upon Huſbandry as a profitable Occupation; but when we come to the Practice of it upon the Rules laid down in this Treatiſe, as an intelligent Perſon will put them in Uſe on every Article, we ſhall find that the Produce of Land, where the moſt Expence is employ'd upon it, inſtead of being three or four times equal to the Charge, is ſix, ſeven or eight Times, and often much more.

This may tempt many into the Profeſſion, who have Genius capable of improving it, which will be an Advantage not to themſelves alone, but the Kingdom; and it may ſhew thoſe who are employed in it already, how extreamly it will be worth their while to ſtudy the Rules and Nature of its Operations more deeply, as every Part of their additional Knowledge will be an Addition to their Income.

Having obſerved thus much in general, as a Concluſion of what we had to ſay on that great Article Plowing, we ſhall now come to the Conſideration of thoſe other Operations which are us'd to aſſiſt that original Device in the Improvement of Land by Tillage.

CHAP. XXXVII.

Of Harrowing.

THE Husbandman understands that the great Purpose of Tillage is to break the Earth into small Pieces. He sees how the Plow begins this Work; cutting it up from some Depth, and throwing it by, in Quantities more or less broken, according to the Nature of the Soil and the Form of the Plow: but though this is a very material Part, it is not all that is to be done in the preparing Soils for Corn. The Harrow and other Instruments are to follow, whose Use is to break and divide the Furrows still more.

The harrowing is the Operation that follows that of plowing, and therefore is proper to be considered next after that.

In the old Husbandry they employed Men to follow the Plow with Instruments they call'd Hacks, these were a Kind of Hoes, but stronger in the Handle than those Instruments, and hollow in the Blade, which was well steel'd.

These People, whom from the Instruments they us'd, they call'd Hackers, were to follow the first plowing, and to cut and hack the larger Lumps to Pieces, and after these followed the harrowing. But the present Practice having greatly improved the Plow, there is no farther Need of that Instrument or that expensive Manual Labour, but the next Operation to plowing is the harrowing.

This is done by an Instrument armed with Iron Points, which being drawn over the Ground, tears up the Lumps left unbroken by the Plow, and breaks them to Pieces.

The Harrow is drawn by Horses, and accordcording to its Form requires more of them or fewer, and does more or less Service, but in general it breaks the Ground, and brings up a great deal of good Mould.

Various Methods are used as to the Article of sowing, according to the different Practice of Husbandmen in different Places, and with respect to the Kinds of the Crop, all which are to come hereafter into Consideration. But here it may be proper to observe in general, that the Harrow, besides its Use already named in breaking the Ground, has another, which is the covering of the Seed.

It is repeated one or more Times, for the sole Purpose of breaking and dividing the Clots, and when the Corn is sown upon the Land thus till'd, or otherwise, the Harrows are to be drawn over it again, to cover the Seed: this must be done with Care, and it answers a double Purpose; for beside the covering the Seed, it breaks the Clods once again, and scatters a fine Dust over the Seeds, which is of the greatest Service in their first Growth.

We have seen that the Plow answers to the Purpose of the Spade in Gardening; and in the same Manner the Harrow serves in the Place of the Rake. The Plow is a Spade drawn by Horses, and the Harrow is many Rakes fastened together, and worked in the same Manner.

The lighter and looser the Earth, the more compleatly the Plow breaks it, and the less Need there is of the Harrow; but there is no Ground whatsoever that will not be the better for the harrowing, which covers the Seed. When this is omitted it is thrown among loose Clods of Earth. It is left in a great Degree naked, and is ready for all Kinds of Vermine that devour it; and when it shoots has neither fine Mould about it, nor is able to penetrate these tough Lumps. It languishes therefore in a Soil that would, in proper Order, be very well able to support and nourish it, and this proper Condition will be given it by the Harrow.

But let the Husbandman, while he makes himself sensible of the Advantages and Benefit of harrowing, be cautious that he do not expect too much from it, or depend upon it in Cases where he should have Recourse to more powerful Methods of breaking the Ground. This is a Caution the more necessary, because it is an Error that the present Farmers very frequently run into. They often neglect to give their Land a due plowing, trusting to the Harrow to make it fine. When they have thrown in their Seed they go over it with a Harrow, and being sensible that the Clods of Earth must be broken, and that they have not done this sufficiently with the Plow, when they see once or twice harrowing does not effect it, they go over the Ground again and again, till the Feet of the Horses have trod the Soil into a Hardness that is very unfit for the Growth of any thing.

There are Soils in which treading, at a proper Season, is serviceable to give them a Firmness, which they naturally want, but in others nothing is more destructive.

CHAP. XXXVIII.

Of the various Kinds of Harrows.

THE Harrow, as it follows the Plow in Use, so in all Probability was the Instrument next invented after it. Like the Rest it was clumsy and inconvenient in its first Contrivance; and has been, from time to time, improved more and more, by the Ingenuity of Husbandmen. We shall consider it under the Forms it has got in these several Alterations, and shew its Use in the plainest and in the most perfect State.

The common Harrow is an Instrument too well known to need much Description, it consists of cross Beams and Iron Spikes; and all that we shall advise the Farmer respecting it is, that he have it made firm and solid, for no Instrument in all his Profession suffers more by being made slight than this. Let him see that the Spikes, or Tines, are large and well fix'd, and in the working let him have an Eye that it go evenly over the Ground.

The great Harrow differs from this principally in its Bulk, and the Solidity of its Structure. It is a stouter Instrument, and every way better fitted for Service. It consists of eight Beams, disposed cross-wise, as in the common Harrow. These are seven Foot long, and four Inches and a half square. The Iron Spikes, or Tines, are like

like the Wood-work large and maſſy; they are twice as thick, and once and a half as long as thoſe of the common Harrow. The Wood-work of this Harrow ſhould be Aſh, and a good Workman muſt be employed; for if it be not framed very well together, it will tear itſelf to Pieces preſently in the working. The Joints of the Woodwork muſt be all firm, and the Tines fixed in the moſt ſecure Manner; and then it becomes a very ſerviceable Inſtrument. The Tines in this great Harrow are to be placed at the ſame Diſtance as in the common Kind.

The Uſe of this Harrow is for breaking the Ground, not for covering the Seed; for that is to be done in the ſame Field with the lighter Harrow. This requires commonly three Horſes to draw it: and in very ſtrong Lands ſometimes more; but by its Weight, and the Length of its Tines, it tears away very deep, and has a Force to break the Clods much better than the common Kind. This is fitteſt for the ſtubborneſt and hardeſt Kinds of Land; and is there of ſuch Service, that the Farmers think its Effect equal to a ſlight Plowing.

It may be dangerous for the Huſbandman to truſt to it in this Reſpect ſo far as to neglect the neceſſary Plowings; for at the beſt it is not equal to that Operation; but following it, and in ſome Lands following the Roller, it will be found of vaſt Advantage.

The Drag is an Inſtrument of the ſame Kind with the Harrow, and differs in nothing from the great Harrow laſt deſcribed, but in the Weight and in the Awkwardneſs of the Contrivance. The great Harrow is ſufficient for all Purpoſes of tearing up the Ground in that Manner, therefore this Invention was unneceſſary.

The Drag is compoſed of eight Beams, each eight Foot long, and of a great Thickneſs; they are placed croſswiſe, but at Diſtances much larger than in the great Harrow; and the Spikes which are very thick and long, ſtand alſo at greater Intervals: this unwieldy Inſtrument cannot be managed with leſs than four Horſes, and ſometimes they add a fifth, the four in Couples and the odd one alone in Front. In this Way the Thing is lugged along very unevenly and irregularly; it digs deep, and tears up a great deal, but the Diſtance between the Tines makes it leave a great deal untouched, and a great many Clods unbroken.

The principal Uſe that is made of theſe Drags, is in the preparing of Land newly plowed up from Sward. When the Soil in ſuch Caſes is rich, and the Turf tough, there is nothing more difficult than the getting ſuch Land into Tilth. We have already, under the Article of Plowing, explained the Difficulties of this Article in the Huſbandman's Buſineſs, and recommended the doing it by Means of the four coultered Plow. As we have here mentioned the Uſe of a Drag as being common to this Purpoſe, we muſt caution the prudent Reader from being miſled by the common Method in this Reſpect, for often nothing is a worſe Practice.

When a Land of this Kind has been plowed up in the common Way, the Furrows being large, the Turf lies in long Ropes, and will continue growing. To prevent this, theſe Furrows muſt be broke to Pieces. This has been try'd among the earlieſt Huſbandmen by croſs Plowing; and of later Times by the [illegible] ſtrument, the Drag, but both with very [illegible] Succeſs.

In the common Way with the Plow, which is the old Method, they lie too looſe to make a due Reſiſtance to the Coulter; and ſo they riſe before it, and are dragged into irregular Heaps, and thus left about the Field inſtead of being cut to Pieces. In this Caſe, the Turf, inſtead of rotting, grows on, and defeats the Purpoſe of the Tillage.

In the other Way by this Inſtrument the Drag, it is ſtill worſe. The Practice is to lug this acroſs the Field in order to tear the graſſy Furrows to Pieces; but this cannot ſucceed to any Purpoſe, for theſe Furrows are very firm and tough, and require a keen Edge to cut them. As the Coulter could not do this in the former Attempt of croſs Plowing, it is impoſſible the Tines of this Drag ſhould do it, becauſe they have no Edge; and, in general, although ſome Parts are torn to Pieces this Way, yet the moſt of the turfy Matter is in a worſe Manner dragged up in Heaps, and the under Part of the Earth is often left bare for great Spaces together.

This is not anſwering any Purpoſe: we have ſhewn already what Method is to be uſed on the Occaſion; and as this Inſtrument the Drag does not ſucceed here, neither will it anſwer to any other uſeful Purpoſe. We have mentioned its Form and Make, that nothing might be deficient; but we adviſe the prudent Huſbandman to have nothing to do with it: let him truſt to the common Harrow in light Soils, and have Recourſe to the great Harrow in the others, and he will need to trouble himſelf no farther on that Head.

We have now to mention another Kind of Harrow, ſince it is cuſtomary to call it by that Name, which is uſed in Graſs Lands; and from that we ſhall paſs to the Structure and Uſe of that natural Contrivance, the Drill Harrow, which will be treated in a diſtinct Chapter.

The Harrow uſed on Graſs Lands, is not compoſed of Beams and Tines as the other, but of ſome ſlighter Wood-work and Buſhes, it is thence called the Buſh Harrow, and is uſed for ſpreading the Dung or other Manure, carefully and evenly over their Grounds. Its Benefit is very great, tho' of a Kind altogether different from that of the common Harrow, the Sort before deſcribed. The Uſe of that is to break the Clods of Earth, the Buſineſs of this is to ſpread what is laid upon the Ground for enriching it.

We have already in our Second Book, treating of Manures, named thoſe ſeverally which are to be uſed on Paſture Grounds. Whichever of theſe are employed, let the Farmer as ſoon as ever he has got it ſpread upon the Ground, ſend in Women or Children, or others who work cheap, to pick up the Sticks, Stones, or whatever other Rubbiſh may have come among it; and as ſoon as this is done, let him have Recourſe to the Buſh Harrow, for the more perfect dividing and diſtributing the Manure.

Whatever Care may have been taken in ſpreading it by Hand, many of the Clods will remain unbroken,

unbroken, and it will be thicker in ſome Places than in others: it is the Intereſt of the Farmer to have it broke perfectly to Pieces, and to have it ſpread and diſtributed equally, and this is the Office of the Buſh Harrow.

If the Manure be of the tender Kind, as the Bottoms of old Hay Stacks, very rotten Dung, or the like; he may immediately draw this Harrow over it, and it will break and diſtribute it very well: but if it be of a harder Kind, as the Mud from Ponds that has any Firmneſs, or the like; then let him leave it ſpread on the Ground for ſome Days, and after the Sun has crack'd the Lumps, take the Advantage of the firſt Shower, and immediately uſe his Buſh Harrow.

Having thus directed the proper Uſe of this Inſtrument, we ſhall deſcribe its Make, which is the plaineſt and moſt natural in the World. Nothing ſavours ſo much of the old Original Huſbandry, as this Inſtrument in its firſt State, nor is it much more elegant in the neweſt Improvements.

The Original Buſh Harrow conſiſted of a Hawthorn cut freſh from the Hedge, and a little loaded to preſs it down; this is ſtill uſed in ſome Places, and, when rightly manag'd, does as well as any, the Method is this.

Let the Farmer look among his Hedges for a ſmall leav'd Hawthorn: theſe naturally are more buſhy than thoſe with broader Leaves; and let him chuſe out the moſt ſhrubby that he can find. Let him cut down a large Stem of this, where it may be beſt ſpared, and laying it on the Ground beat and preſs it as flat as he can with a Board, breaking the Branches as little as may be. Such Boughs as will not be preſſed down muſt be cut off, and thruſt into the Body of the Buſh in the openeſt Places; and ſome other Boughs from the Hedge may in the ſame Manner be thruſt in to thicken it, if there be Occaſion. Theſe added Buſhes are to be well tied in, and when the Surface is flat, full, and very rough, let it be laid on the Ground again, and two or three good Logs of Wood tied on upon the Back to make it firm and heavy.

The Harneſs of a ſingle Horſe is to be fix'd to the End of the Stem where it was cut off, and thus it is to be drawn over the Ground. It will tear and ſcatter the Manure in a very excellent and perfect Manner.

This is the Original Form of the Buſh Harrow, as our oldeſt Writers deſcribe it, and as it was doubtleſs practiſed from the very firſt Invention of manuring Paſture Ground: its Improvement brings it nearer the common Harrow in Form, but the material Part is the ſame; for the Work is performed by natural Buſhes. The Method of making it is this.

Lay an old Gate upon the Ground, but let it be one that is not rotten, but will hold well together. Let there be a Parcel of Blackthorns cut up, and take the buſhyeſt and rougheſt of theſe. Draw them in, and work them between and among the Bars of the Gate, faſtening them by Nails, Cords, and otherwiſe, till the whole Surface be well covered, and very rough: then turn it up, and the buſhy Part lying to the Ground, it is fit for Uſe. The Traces are to be fixed to the Center of the Gate that it may draw evenly, and it is to be dragged over the Ground as before. This is a more compact Inſtrument than the other, but it is heavier. The Bars of the Gate ſerve as the Wood-work of the Harrow in the other Kinds, and the Buſhes anſwer the Purpoſe of Teeth. The Blackthorn is prefered to the common Whitethorn on this Occaſion becauſe it is tougher, and the Thorns are harder. It would be better for the other Purpoſe as well as this, were it not that it does not grow large enough to be uſed ſingly.

Which of theſe two the Farmer ſhall prefer, muſt be determined by the Nature of the Manure he has uſed. The Convenience of the firſt Kind is, that it is eaſily drawn; the Advantage of the other is, that it is heavy and ſtrong. When the Manure is of the tenderer Sorts the firſt Kind is beſt; but when it is tougher, and the Clods require more breaking, that made with the Gate is beſt.

All theſe Kinds of Harrows are to have a Hook of Iron for the faſtening the Traces to them by which they are to be drawn; and this ſhould be well fixed on the Inſide that it may not ſtir.

The Holes where the Tines are let in in the common Kinds, are called the Bulls, and the Tines are in ſome Places called the Tuſhes, and the Pins; in others, the Nails of the Harrow.

CHAP. XXXIX.

Of the Drill Harrow.

THIS is a Harrow of a particular Form, and of very late Invention, but it is of excellent Service. The Drill Huſbandry is one of the greateſt Improvements made within this Century, and this Inſtrument is a Part of the Preparation for it.

The Method of Drilling is this; when the Ridges are properly raiſed, and are become moiſt enough at Top, they are harrow'd once, and that only lengthwiſe, and then they are drilled. Once Harrowing is generally ſufficient, but the Eye of the Farmer is to judge whether it be or not; and, if not, he is to order it to be repeated.

If he find after this once Harrowing, that the Tops of the Ridges are not levelled fit for the Drill to paſs thereon, and reach to the due Depth, the Ground muſt then be harrowed a ſecond or a third Time, till it be in a proper Condition.

The Land being thus perfectly prepared, the Drill is to be brought on. This makes Channels for the Reception of the Seed; and that theſe may not remain open, the Drill Harrow follows, and drawing the Earth together fills them up.

The harrowing of the Ridges to prepare for the Drill, is to be performed by the common Harrow. The Drill Harrow follows the Drill Plow, and is of no other Uſe than the covering up the Seed in thoſe Trenches wherein it is laid, by this particular Method of Huſbandry.

It was needful to ſay thus much in this Place

to explain the Nature of the Operation of this Inſtrument, all which will be underſtood more fully when we come to treat of that Method at large; but having thus far explained it on the preſent Occaſion, we ſhall be underſtood in the Deſcription of the Inſtrument itſelf.

This, for ſo uſeful a Thing, is exceedingly plain and ſimple. It is never uſed alone, but always to follow the Drill Plow; and it conſiſts only of two Beams, by which it is faſtened to the Plow; a croſs Bar fixed to thoſe two Beams, and a Couple of wooden Teeth let into that Bar: theſe are all its Tines.

We ſhall deſcribe here particularly the Dimenſions of that uſed as a Part of the common Wheat Drill Plow. The Harrow which moves on its Beams covers the Seed: and is thus conſtructed.

The Legs are a Couple of narrow and flat Pieces faſten'd to the Beams of the Plow at their Tops, on the Inſide of thoſe Beams: the faſtening is by a Couple of ſtout Iron Pins, which paſs through the Tops of the Legs, and the Beams of the Plow, and are faſtened on the Outſide of thoſe Beams by Nuts and Screws. Theſe Pins are to be made ſquare where they paſs through the Beams, that they may be held the faſter, and may not be able to turn round in them; but they are to be round near the Heads that the Harrow may move the more freely on them. The other End of theſe Legs of the Harrow is cut round, and they are let through the croſs Bar, which is called the Head of this Harrow, by Holes made for that Purpoſe, and are pinned in behind it; that either Tine of the Harrow may deſcend at the Time the other riſes, where the Ground is uneven. The two Tines are flat Pieces of Wood, they are let thro' the croſs Bar or Head at two and twenty Inches Diſtance from one another. They are to be pinned in above the Head; and each is to have a Shoulder underneath. Theſe are to be ſet ſloping, ſo that if they take hold of any Clods, they do not drive them before them, but riſe over them.

They muſt be of ſuch Length as to give Room for the Harrow to ſink and riſe without moving the Shares up; and to give them the more Room to move, the Legs of the Harrow are to be bent downwards, towards the Middle.

By the Diſtance of two and twenty Inches allowed to two Tines of this Harrow; each Tine going three Inches and a half on the Outſide of each Channel that is next it, fills it up with Earth upon the Seed from the Outſide of it. This gives an Inch in the two Rows Diſtance when they riſe; for, as they will come up nearer the Inſides becauſe the Earth is thrown in nearer the Outſide, they will ſtand but fourteen Inches aſunder, tho' the Channels were made at fifteen Inches. The ſloping of the Points alſo, which is always to be made outwards, brings in ſo much the more Earth to the Channels.

When this Harrow is found to be too light, a Stone is to be tied to the croſs Bar or Head, and faſten'd evenly upon the Middle of it; or a Box made of Boards, and fitted on in that Place is uſed, which is filled with Earth or other

weighty Materials to keep it ſteady. A triangular Harrow with many Tines, may alſo be made for uſing between the Rows in the Horſe-hoeing Huſbandry.

In moſt Lands, and on moſt Occaſions, the Harrow, which is a Part of a Drill Plow, is ſufficient for the Purpoſe of covering the Seeds, but it will not always anſwer; and the Farmer is not in favour of any new Contrivance, to give up the old when they may be uſeful.

For Inſtance, there are many Occaſions on which the common Harrow may with great Convenience be called in to aſſiſt this Drill Harrow in covering the Seeds.

In tough Soils when the Land is drilled late, and the Earth is moſt, it will ſtick to the Shares in great Quantities; and in this Caſe not only the Motion of the Plow is hurt, but the Channels will be in Part left open by the Drill Harrow.

For theſe Reaſons it will be beſt in ſuch Land to take off the Drill Harrow from the Plow, and truſt to the covering of the Seeds up in the Channels, entirely to the common Harrow.

When the Drill Harrow is taken off, a Man may follow the Plow in theſe Soils with a Paddle, or a forked Stick in his Hand, to clean the Sheats from this ſtiff Dirt. In this Caſe the Channels, with the Seed in them, will lie in many Parts open, and a common Harrow is to be drawn over the Ground to cover them: for this Purpoſe if the Farmer ſhall rather chuſe to improve his Drill Harrow than to employ the other, it will be proper for him to order it in this Manner. Let the Tines be of Iron inſtead of Wood; and let the Legs be placed at the End of the Plank, remote from the Sheats of the Plow. In this Caſe the Sheats may be cleaned, tho' the Harrow be on, and theſe Iron Tines will not fail to cover in the Channels.

The Drill in this Caſe ſhould have only two Shares, and they ſhould ſtand at about fourteen Inches Diſtance. In this Caſe the Harrow anſwers its Purpoſe in ſpite of the Inconveniencies of the Ground; and the Harrow, beſide its common Uſe, ſerves to turn it.

This is the Way of making the Drill Harrow anſwer on all Occaſions; but it is a very good Method for Wheat in particular, to draw a common Harrow once over the Ground afterwards; for nothing lays it ſo well.

For this Purpoſe it will be proper to uſe two Harrows coupled together, as is a common Cuſtom on many Occaſions; and they ſhould in this Caſe be of the common Make, and of the lighteſt Kind; and the Pole that faſtens them together ſhould be tied in two Places, that they may always go level.

This is a proper Caution for harrowing all Land that is in Ridges; for otherwiſe the Ridges will be too ſharp at the Top, and the Partitions might lie higher than the Rows. Two Harrows thus joined together, go as level and even as one.

The harrowing of Ridges muſt never be croſswiſe, unleſs they are to be made level for croſs Plowing, in order to lay out the Ridges in a Breadth different from that they had before.

When the Ridges are too high, they may be

lower'd by this Kind of Harrowing; and it is not attended with the common Miſchief of treading down the Ground, for the Horſe when he draws two light Harrows thus joined together, always treads in the Furrow that is between them.

CHAP. XL.

Of Rolling.

ROLLING is like the preceding Practices, an old Method of Huſbandry. Even in Times when the Uſe of that convenient and familiar Inſtrument, the Roller, was not known, they uſed others to break the Clods of Earth in the ſame Manner as that does it; and theſe, under the Name of Mallets, or Mauls, are uſed at this Time in many Parts of the Kingdom: the Roller is, however, ſo much more convenient, that it ought to be taken every where into their Place.

As Harrowing is on ſome Occaſions performed before, and on ſome after Sowing, ſo is Rolling: and it is alſo ſometimes uſed before, ſometimes after Harrowing; and very frequently and properly between the two Harrowings of the ſame Piece of Ground.

The great Uſe of all Tillage is to break and divide the Ground; and where there are Lumps of a dry and brittle Earth, the Roller anſwers very well to that Purpoſe. It ſhould be on this Occaſion uſed only on ſuch Lands; but the Huſbandmen of ENGLAND, for want of making theſe Diſtinctions, do themſelves great Injury.

In Barley Land the Roller has another Uſe. It not only breaks the Clods of Earth, but ſmooths and levels the whole Surface of the Ground that it may be fit for Mowing.

In the old Huſbandry when they had ſown the Ground, and harrowed in the Seed, they uſed to go over it with a great wooden Beetle, with a heavy rounded Head: with this they broke the Clods they found left by the Teeth of the Harrow; and when even this Practice had not divided them ſufficiently, they afterwards took the Advantage of the firſt good Shower, and went over the Field again with another Kind of Beetle, and beat and broke them again. This laſt Weapon, inſtead of the round Head of the other, had a flat Piece of Board faſten'd in a ſlanting Direction to the Handle, and of about a Foot ſquare, and two Inches thick. This they uſually made of Aſh, or ſome other tough Wood, and by its Blows ſtriking it down and drawing it back, they broke and pulled the Lumps to Pieces, which had eſcaped the Teeth of the Harrow, and had not been ſufficiently divided by the former Beetle.

Theſe were the Operations of the old Huſbandry, and theſe are ſupplied by the Roller in the ſame Manner, only with more Convenience and Eaſe. But here a great Caution is to be given the Huſbandman, that he do not, by an improper Uſe, make that hurtful which might be very beneficial. As the Intent of all Tillage is the properly dividing of the Ground; when the Roller breaks the Lumps of Earth it anſwers that Purpoſe. It does this when it is uſed on proper Soils, and at proper Seaſons; but otherwiſe it may take an exactly contrary Effect.

Thus, when the Earth is of a tender Kind, and the Seaſon dry, the Lumps are no Way whatever broken better than by the Preſſure of the Roller: but if the Farmer will draw this heavy Implement over a Piece of Land that is of a tough Soil, and in a damp Condition, he will preſs it into Cakes inſtead of breaking the Lumps; and taking juſt a contrary Effect to what it ought, this Inſtrument will in a Manner un-till the Land inſtead of tilling it.

This is moſt miſchievous of all when it is practiſed after the Seed is ſown; for, in that Caſe, it ſqueezes the Soil into Cakes above it, which its tender Shoot will not well be able to pierce; and makes it ſo tough and ſtiff about it, that the ſmall Roots will very difficultly make their Paſſage.

This is the Condition of ſuch Land before it is tilled, and the rolling it after ſowing in this Manner, does a great deal toward reducing it to the old Condition again.

All ſtrong Land when it is broken and divided by Tillage, is put out of its natural Condition; and it is from that Time the Tillage is ended, ſubſiding and ſaddening into its old Condition again. This is the Huſbandman's great Misfortune; but he muſt be very blameable indeed if he aſſiſt it, as he certainly does in a very powerful Manner, when he rolls ſuch a Piece of tough Land in a moiſt Seaſon after Sowing.

From this reaſonable Account of the Nature of Tillage, and of the Effect of Rolling, it will eaſily be ſeen that the great Uſe of that Inſtrument is on light Soils, and in dry Times; and that its beſt Service is when it is uſed in the Intervals between one harrowing and another.

For Barley Land it is very fit to be done after ſowing, rolling with Diſcretion, and avoiding the before-mention'd Errors. Its Uſe, in this Caſe, is evident; becauſe the Smoothneſs and Levelneſs of the Ground makes it fit for Mowing: but, in the other Caſe, it is a proper Inſtrument in the immediate Purpoſe of Tillage, ſerving to break the Clods and divide the Soil.

This is the great Uſe of the Roller, and 'tis therefore the proper Soils are the light Kinds; the proper Seaſons are the drieſt, and the Place it holds in the right Practice of Huſbandry, is between the Harrowing and the ſecond Plowing.

Thus when a Piece of Land has been plowed once, let it be harrowed: this breaks many of the Pieces that are too large in the Furrows, and tears up the Clods: then let the Roller be drawn over the Ground, it will break in a proper Manner, and the Clods pulled up by the Teeth of the Harrow, and will prepare the Land excellently for plowing again. This ſucceſſive Uſe of the Plow, the Harrow, and the Roller, is the moſt regular and certain Way of breaking and dividing a hard Soil, and bringing it into a Condition to nouriſh the Crop.

CHAP. XLI.

Of the ſeveral Kinds of Rollers.

ROLLERS are of different Kinds, Forms, and Materials. Some are ſimple, and others armed with Spikes, or with Edges. In Gardens they uſe them of Stone or Iron, but in Fields they are of Wood, except the ſhort Roller for Horſehoeing Huſbandry; for the Iron or Stone Rollers would there preſs almoſt any Kind of Land into Cakes, by their Weight.

The common Roller for the Field is made of the Trunk of a good thick Tree. It ſhould be about eight Foot long, made even all the Way, and fix'd in a plain Frame, in the which it can turn with Eaſe, and by Means of the fore Part of which it may be drawn by one or more Horſes, according to its Weight, the Strength of the Beaſts, and the Nature of the Ground. From the fore Part of the Frame there run a Pair of wooden Shafts, and the hinder Horſe is put into theſe for the more ſteady drawing; and turning at the Land's End, without Trouble.

Next after this, which is the common Roller of our Farmers, we ſhall deſcribe that which is us'd in the Horſehoeing Huſbandry, that being a plain Roller alſo, though differing in Size and Materials.

This contradicts the general Practice of making the Rollers of Wood for the Field, in that it is made of Stone. It ſeems of the middle Kind, or to have been contrived between the Garden and the Field Roller, being a ſmall Stone Garden Roller, ſet in a two Shaft Frame for the Convenience of being drawn by a Horſe.

The Conſtruction of this Kind is very eaſy. The Stone is to be a Yard long, and two Foot ſix Inches in Diameter. Of this Size it generally weighs about eleven Hundred Weight; ſo that it is very capable of preſſing firmly, and is ſo ſhort that it is eaſily and conveniently managed.

Its Shortneſs alſo ſuits it excellently for the Purpoſe of that Kind of Huſbandry, becauſe it can conveniently be drawn in the Spaces left by that Method, where the common great Roller could not come.

The Frame of this is very plain and familiar, it conſiſts only of two Legs or Limbers, through which the Axletree comes at each End, and which are joined together by a Couple of croſs Bars near the Stone. This is the whole Contrivance. A Couple of Pegs are driven in each Limber near the Point, which ſerve to faſten in the Horſe, and then this little Inſtrument is ready for Service.

The two croſs Bars are to be of Wood, and they ſhould be tolerably ſtrong, and faſtened into the Limbers by Pins. The Ends of the Axletree of the Stone muſt not ſtand out beyond the outer Surface of the Limbers, becauſe they would do Miſchief by laying hold of the Plants, as this is to be drawn between the Rows; and the hinder Ends of the Limbers ſhould be made to turn a little up for the ſame Reaſon.

The Farmer who ſhall make a Roller on this Plan, muſt remember the Caution we have given of the Mulcher that may be drawn by Rollers, and never uſe it but in the dryeſt Weather; becauſe by its Weight it is capable of doing much more Harm than any other Kind.

It ſupplies in this, which is its proper Seaſon, the Uſe of the Plow and Harrow, breaking the Clods almoſt to Powder; ſo that the leaſt Rains that follow, diſſolve and break them to Pieces.

This Roller, in very dry Weather, is excellent for preparing the Ridges for Turnips. When the Land is in ſuch vaſt Lumps at Midſummer, that neither the Plow nor Harrow can touch them, this Roller, drawn over the Land, will burſt and break them, and it may be eaſily plowed and harrowed afterwards, ſo as to be made fit for the Seed.

In the common Methods of Huſbandry the ſpiked Roller, the Structure of which will be plainly enough underſtood by the Figure, is excellent to ſubdue the ſtubborn Land in dry Summers.

When the Ground can no other Way be got into Order for Turnips, this Roller, followed by the great Harrow, deſcribed in a preceding Chapter, are excellent.

We have added alſo in this Place, the Figure of that particular Roller, we have deſcribed under the Article of Burnbaiting. This may be called the edged Roller. The only Caution needful to be given the Farmer about this is, that he make the Roller itſelf heavy enough, and the Blades ſtout enough, and ſharp enough. They will be uſeful on other Occaſions, beſide that of Burnbaiting, as has been obſerved already; and indeed on whatever Occaſion there is to cut through long and ropy Furrows, no Inſtrument is ſo proper.

CHAP. XLII.

Of the great Advantages of Rolling.

HAVING, in the two preceding Chapters, given the Reader an Account of the Methods of Rolling, acquainted him with the Form and Structure of the ſeveral Inſtruments us'd for that Purpoſe, and cautioned him againſt the Miſtakes into which he might otherwiſe have fallen in the Uſe of them; we ſhall here deliver more at large the Advantages attending the Uſe of that Inſtrument, all of which are perhaps not ſufficiently attended to any more than all the Inconveniences.

The great Miſchief that may attend the Practice of rolling, is the preſſing down and hardening the Ground; but we are to remind the Farmer, that there are Lands of ſo very light and naturally looſe a Kind, that this preſſing them down may, at a proper Seaſon, inſtead of doing Miſchief, be an Advantage to them.

We have mentioned the Good Sheep do to certain light Soils, by treading them when put upon them: and theſe when they are of the moſt crumbly Kind, are often rendered ſo looſe by the Weather, that they cannot afford a ſufficient Hold to the Roots of the Crop. In this

Caſe

Caſe the Uſe of the Roller is excellent, for it preſſes and fixes the Soil.

This is ſo neceſſary in ſome Places, that the Farmer, though he plow and otherwiſe work his Soil ever ſo well, if he omit to roll it will never get half his Crop. Chalks, and the white clayey Soils, are of this Kind; and ſome others.

Barley is the Crop they roll the moſt conſtantly; but taking proper Opportunities, and doing it in a right Manner, it is equally ſerviceable to Beans, Peaſe, and other Kinds, not excepting Wheat. It anſwers many excellent Purpoſes, and at once ſtrengthens and preſerves their Growth.

One material Advantage of Rolling is, that it deſtroys Inſects, and particularly the naked Snail, commonly called the Slug. This Creature breeds in great Quantity among the young Growth, and devours immoderately. Of all Crops Peaſe are its Favourite, and it eats them from their firſt Shoot, till the Time of gathering. The great Abundance of this Creature is in the Beginning of Spring, eſpecially if the Seaſon prove warm and ſhowery; and its principal Time of eating is the Morning eſpecially, very early; for as the Day riſes it gets into the Ground.

This Knowledge of the Nature of the Creature, will inform the Farmer how he is to deſtroy it.

The Beginning of Spring is the Seaſon for Rolling, and he muſt do it very early in the Morning, while the Creature is above the Ground.

Let him obſerve the Cautions already given, and avoiding thoſe Miſtakes with Reſpect to the Nature and Temper of the Soil, and he will at once, by this Practice of Rolling, deſtroy the Enemy of his Crop, and make the looſe Earth firm for its Support.

It falls out happily for him that the Time of the Slug's greateſt Abundance, is the very Seaſon for Rolling his Field in another Reſpect, becauſe his Crops are at this Time in a Condition to bear it, which they will not when they are more grown.

The Seaſon for rolling Corn is the Beginning of APRIL, and the beſt Method is to roll that which lies in broad Lands twice in a Place, beginning at Day-break.

In dry and looſe Soils the Roots of Corn are apt to be parched and burnt up in long Droughts, and they will ſuffer greatly by but moderately hot and dry Weather while they are young. The Cauſe of this is, that this looſe Earth not cloſing about their Roots, gives Paſſage to the Air and Sun directly to them. Here the Roller comes into great Service, for it preſſes and flats down the Surface of theſe light Soils, and puts them into the Condition of ſuch as are heavier.

This rolling the Earth while the Corn is young, has alſo the Effect of giving them another Dreſſing, for it breaks and preſſes the little Lumps of the Soil to Pieces, and this is one great Article of Tillage as has been ſhewn at large before.

But in all this the Farmer is to take Care that he do not, by rolling improperly, do more Miſchief than he can poſſibly reap Advantage. We have adviſed him againſt rolling tough Soils, and againſt rolling any in wet Weather; and this laſt is ſo needful a Caution, even with reſpect to the lighteſt Lands of all, that if he ſhould attempt it he would deſtroy his Crop. The Feet of the Horſes would, in this Caſe, do incredible Miſchief, beſide the Action of the Roller.

Corn muſt be at a proper Growth before the Roller is introduced; that is, the Leaves muſt be ſtrong, but the Stalks muſt not be at all hardened. And though moiſt Weather is known to call out the Slug, the Farmer muſt ſtay for ſome that is dry, before he can take this Method of killing it.

When a light Land is roll'd at a proper Seaſon, it becomes ſo preſs'd about the Roots of the Corn, that it is able to ſupport the Stalks as they grow up, whereas otherwiſe they would have rocked about and fallen: but this muſt be done before the Stalks are grown to any Height, or have acquired any Strength, for when they have got a little Firmneſs the Roller breaks them, and they never recover it.

For this Reaſon Wheat in a very looſe Soil, may be rolled in OCTOBER and NOVEMBER, and in JANUARY, FEBRUARY, and MARCH; the Winter rolling will prevent the ill Effect of Froſts, as the Spring rolling will that of Droughts.

Great Care is to be employed alſo in the rolling of Barley. This muſt not be rolled too young, for then the Preſſure of every little Clod will cruſh and deſtroy a Leaf, and the Root having little Strength, will not be able to renew it; and if it be roll'd too late the ſame Miſchief will happen as juſt named of Wheat; that the Stalks will be broken, and the Crop that Way ſpoiled.

Upon the whole, the prudent Farmer will ſee that there is not any Part of his Profeſſion which requires ſo much Judgment as the rolling Corn Lands to Advantage. We would not have ſhewn the Benefits, without firſt laying down the Cautions in a very ſtrict Manner; and here we are obliged to give more. The Soil, the Growth, and the Weather, are all to be very carefully obſerved: when all theſe favour, the Benefit of rolling will be very great; but when they do not the Miſchief may be greater.

This Roller is us'd on Paſture Ground as well as Corn Lands, with conſiderable Advantage, the Seaſon for that is MARCH, the Earth being then a little moiſt. It cruſhes down Worm Caſts and ſmall Ant-hills, and riſing Mole-hills, eſtabliſhing the Earth about the Roots of the Graſs, and making the Surface level for the Scythe. There will need no farther Caution on this Head, but that the Roller muſt always be of the heavieſt Kind.

BOOK VI. PART IV.

Of the different Manners of Sowing.

CHAP. XLIII.

Of Sowing in general.

WE are here treating of Husbandry, and its several Operations; and in whatsoever Method we should have disposed these, there would have been Room for those who love to cavil, to have disputed the Propriety of the Order. It arises from this, that the Operations of Husbandry are not limitted to one Time, or one Use, but the same Procedure answers several Purposes, and is equally proper at different Times.

Rolling is perform'd, on some Occasions, before the Seed is sown, and on others, after that Operation. In the first Case it serves like the other Practices for that Time, to break and divide the Ground; and in the other to destroy Vermin, to fix the Earth to the Roots of the Plants, and to prepare the Surface of the Ground for the Scythe. 'Tis the same with harrowing, which serves in one Case to break and prepare the Land for the Seed, and in the other to cover it. We might therefore have introduced this Article of sowing before, or after, those Operations; but we have chosen to introduce it afterwards, because those several Articles being now dispatched, there will be nothing to break in upon the Course of our Method, when we proceed from the ordinary Manners of sowing, to that excellent and great Improvement made by what is called the Drill Husbandry, which naturally leads to the Article of Horsehoeing, and thence to the cutting and carrying in of the Crop, according to the proposed Method in our Plan.

We have been very particular in cautioning the Farmer, when he is about to raise a Plantation, to chuse properly his Seeds of the Trees; there certainly is as much Cause to be careful in the Choice of those, for his Arable Land: and many of the same Cautions hold good with Respect to both, wherefore we refer the Reader for many Things, to that Part of our Work, that we may avoid Repetitions.

The first Consideration in this Respect is the Kind and Soundness of the Seed, concerning which we shall give proper Directions, as also for the steeping it to promote and encourage its Growth; we are here distinctly to consider the Article of Sowing.

Let the Seed be had from another Land, not the Farmer's own, on which it is to be sown again; and it will be best if, with a proper Degree of Goodness, it have grown upon a worse Land than that whereon he is to sow it.

Even where the Seed is no Way different, and the Nature of the Land the same, it is often found of great Advantage to change it. Thus two Farmers at forty or fifty Miles distance, shall mutually find Advantage in sowing each on his Land the Corn that grows upon the other's.

The Seed from a colder Climate succeeds best upon the Land that lies in a somewhat warmer. The English Farmer will be sure to find his Advantage, if he will get from the Northern Counties his Seed for the Southern: this is the same Kind of Benefit with that of sowing Seed from a poorer on a richer Ground: the favourable Climate advances it beyond its natural Goodness.

When it is a dry Soil that is to be sown, wet Weather should be chosen, if the Seed be of a Nature to bear wet; on the contrary, in moist Lands a dryer Season is to be prefer'd.

Let the Farmer sow Wheat in wet Weather. It never is too wet for this Purpose, when the Horses and Instruments can go without clogging. On the contrary, let him always sow Rye in the dryest Seasons, Rye will come up at its proper Time, without Rain; but Wheat, if sown in a dry Season, will be six Weeks, or more, before it appears, if there fall no Rains afterward.

In general Summer Corn does best when sown in dry Weather. Only black Oats are an Objection to this Rule, for they require a great deal of Moisture, and will not do well without it.

Wheat not only will lie without shooting, when the Season is dry, at and after the Time of sowing it; but in this Case a great deal of it will be lost: for while it lies and does not grow, it will be in danger of decaying. Therefore it is better for the Farmer to wait somewhat beyond the common Season, than to sow his Wheat when it is so likely to fail.

As to the Manner of sowing, it differs on many Occasions, and is accordingly expressed by the Husbandman under a Variety of Names. What they call sowing under Furrow, is sowing the Corn in the Furrow, and plowing a Ridge over it to cover it; sometimes they harrow the Land, and sow Wheat or Rye upon it with a broad Cast, some only with a single, and some with a double Cast, and then plow it upon an Edge in broad Lands, when the Land is dry. Some also plow their Land up an Edge for broad Furrows, and sow their Wheat or Rye on it, and then harrow it over. In strong and tough Lands the superficial Methods are best, and the Method of sowing under Furrow is best in lighter and looser Soils: but all these, and the other Methods of sowing at Random in this Manner, are very imperfect, and therefore less need be said about them. Their Imperfection leads us naturally to that excellent Method the Drill Husbandry, by which every thing wrong in the usual Way of Management is set right; and this we shall, according to its Merit, treat of at large,

introducing it to the Reader by thoſe Reaſons on which it is founded, and thoſe Experiments which ſupport them.

CHAP. XLIV.

Of the Depth at which Seeds are to be ſown.

WE ſee that in the Methods already mentioned, the Corn is ſown quite at Random. It is ſcattered in an irregular Manner, and without any Precaution, and cover'd afterwards to an uncertain Depth. It is plain that Irregularity and Uncertainty never can be for the Advantage of any thing, and they ſhould not be admitted in Matters of this Importance.

Certainly Corn will grow from one Depth better than from another, and the more regularly it is ſown the better it will riſe. The Intent of the Drill Huſbandry is to diſtribute it properly, and to cover it in ſuch Manner as beſt ſuits its growing, and this not according to Gueſs, but upon Experience.

All Kinds of Plants are not to be ſown at the ſame Depth, ſome requiring more Moiſture and more Shelter than others, while they lie in the Ground; and ſome rot at thoſe Depths at which others will grow beſt.

To be aſſured more perfectly of this, the following Experiment may be made. Let a Trench be cut of two Foot long, and at one End let it be two Foot deep, and at the other terminate at the level of the Ground, the Bottom all the Way riſing in a ſlanting Direction. On the Bottom of this Trench, all the Way up, let there be ſcatter'd Seeds of different Kinds, and then let the Earth that was dug out be thrown lightly in again, covering the Seeds every where, and filling the Trench up to the Level of the Ground.

It will be found, by this Experiment, that none of all the Seeds which the Farmer has to do with, will riſe when they are buried at more than nine Inches Depth. At ſix Inches ſome Kinds will riſe very well, and other Kinds ſcatter'd with them not at all; and other Seeds do not ſhoot, unleſs they be within an Inch or two of the Surface.

This is a plain Experiment, and there can be no Error about it.

Experiments of the ſame Kind will alſo ſhew, that Seeds of the ſame Species may be buried at a greater Depth in light, than they may in ſtrong Soils. And they will ſhew farther, that certain Seaſons favour the ſhooting of Seeds more than others.

We find that Warmth and Moiſture are the great Articles for promoting the Growth of Seeds. The ſame Kind of Seed, buried at a Depth ſomewhat too great, will ſhoot and ſucceed if the Seaſon prove favourable on theſe two Accounts, which if the Weather had been dry, eſpecially if cold, would have lain there without growing.

In ſome Caſes Seeds will corrupt and grow mouldy, when they are covered too deep for their Shooting; but this is not univerſal. Experience ſhews that they will lie unhurt in this Manner, in ſome Soils, twenty Years: ſo that on turning up the Earth after that Period, and bringing them nearer the Surface, they grow ſpeedily and well.

It ſeems, that in ſome Inſtances, the Seeds of Plants will lie longer than this, for in many Parts of the Iſle of Ely, they never turn up the Earth in a Ditch Bank, but there grows Muſtard upon it, although there were none before upon the Ground, or even in the Neighbourhood of the Place. The ſame Thing I have obſerved about Chelsea, with Reſpect of the Plant call'd Eryſinum, or Hedge Muſtard. This never fails to ſhoot where the Soil has been open'd to about two Foot depth. Unqueſtionably therefore the Seeds of theſe Plants have long ſince, by ſome Accident, been buried in the Earth in theſe Places, and they keep good there till remov'd nearer the Surface, though they lie too deep for ſhooting. Air is an immediate Neceſſary to the Growth of Seeds: it is more required to ſome than others, and none will grow unleſs it can operate in a Degree ſuited to its Purpoſe.

The Huſbandman who underſtands thus much of the Nature of Seeds, will find that he may preſerve any Kind for a long Time good, by burying it in a proper Manner; and he will find, to his more immediate Uſe, that every Seed has a particular Depth, in a moderate Soil, at which it grows beſt. He muſt in his Practice conform to this Knowledge, varying a little according to the Nature of his Soil, ſowing a little deeper than the exact Rule in very light Ground, and not quite ſo deep in ſuch as is very tough and ſtrong. He will ſee the Reaſon of this in the Account before given; for the Air certainly has a greater Effect at the ſame Depths in lighter, than it has in heavier Soils.

When the Farmer has thus much general Knowledge with Reſpect to Seeds, let him come to the particular Conſideration of the ſeveral Kinds, and examine what Depth of Covering agrees beſt with each.

To this Purpoſe Mr. Tull has propoſed the Uſe of what he calls Gauges, and they will determine the Matter with Reſpect to every Kind of Seed, with the moſt perfect Exactneſs.

CHAP. XLV.

The Practical Method of finding the proper Depth for Seeds.

A SEED is to be ſown at that Depth at which it will come up the moſt favourably: every Seed has its particular Depth for a moderate Soil, which is to be encreaſed a little in a lighter, and a little diminiſhed in a tougher Ground, and this is the whole Conſideration. When a Seed is ſown at a leſs Depth than this it is dried up, when at a greater it is buried, if it be much leſs or much greater, it will not grow at all: and if but little on either Side, it will grow leſs perfectly and beneficially to the Farmer, in proportion to the Degree of his Error.

Mr. Tull's Gauges for determining the proper Depth, are made in this Manner. Saw off twelve Sticks, of three Inches Diameter; and bore

bore a Hole in each Stick, and drive into the Hole a taper Peg. Let the firſt Peg be half an Inch long, the next an Inch, and ſo on; every Peg being half an Inch longer than the former, ſo that the laſt Peg will be ſix Inches long.

When the Gauges are thus prepared, dig up well a Piece of Ground on the Land where the Crop is to grow. We may make ſome Gauges longer than thoſe here mentioned, if it were done for Curioſity, and for the Trial of many Kinds of Seeds, as in the Trench before-mentioned; but theſe are fully ſufficient for all uſeful Purpoſes to the Farmer, and we now write ſolely with that View.

When this Piece of Ground is dug and well broken and divided, let the Surface be laid even, and let the Farmer make twenty Holes with his half Inch Gauge in a Row, drawing a Packthread Line acroſs the Piece of Ground for that Purpoſe. Let him have ſome choice Seeds, and put twenty of them in the twenty Holes. This done let him cover them up, without raiſing the Earth over them; and ſtick down the Gauge at the End of the Row. The Seeds will be thus buried half an Inch deep, and no more, and the Gauge being left will be a Rule to know it.

In the ſame Manner let him uſe the other eleven Gauges, and after making twenty Holes with each, and putting twenty Seeds in them, let him cover them up, ſticking the Gauge at the End of the Row, and wait the Event.

He will ſee which come up firſt, which grow beſt, and which do not ſhew themſelves at all. From obſerving which Depth anſwers beſt to that particular Seed, he will ſee what is the proper Depth for ſowing it in his Field: and this is the Foundation of the Drill Huſbandry. So ſimple and ſo rational is the Original of that excellent Improvement.

In this Manner let the Farmer try every ſeparate Seed before he ſows it, and thus knowing its proper and favourable Depth, let him ſet the Drill accordingly. Black Oats, when the Drill is ſet too deep, will ſcarce come up at all; and moſt Kinds, if ſowed too ſhallow, are vaſtly injured; a great Part of the Seeds not ſticking root, and thoſe which do, growing in general but poorly.

In general the Danger of ſowing in Winter is, the letting in the Seeds too deep, as in the Summer it is the ſetting them too ſhallow: and in tough Grounds the great Caution is to be us'd againſt going too deep; as in the ſoft and tender Soils, it is moſt likely to err in ſetting them too ſhallow.

The Farmer who tries the Seed with his Gauges upon the Ground where the Crop is to grow, makes himſelf the moſt ſecure that can be: and as he can, by properly ſetting his Drill, be ſure to let all the Seed for his Crop in at the ſame Depth, he will not fail of Succeſs, according to his Pains and Care.

It is beſt to repeat this Method for every Field; but he who wiſhes to ſpare himſelf that Trouble, when he thus knows by Experience the proper Depth in one Place, may vary a little in others, according as they are tougher or lighter Soils.

There is a farther Advantage attending this Practice of ſetting the Seeds by the Gauges, for it ſerves to inform the Farmer exactly of the Goodneſs of his Seed. This is a very important Point, and very difficult to be determined with any Degree of Certainty: Seed Corn may have Faults that eſcape the Eye, and will not be diſcovered by any of the common Methods of Trial. If it be good there is no Reaſon he ſhould ſow more than the neceſſary Quantity, for that is all the Price thrown away, beſide overloading the Ground; and if it be indifferent it is fit he ſow the more of it, elſe he will be defrauded of his Crop. He will know what he is to do from the Succeſs of the Seeds ſet by his Gauge.

He will find the Depths at which they will come up, and mark that at which they ſucceed beſt, and this is to be his Rule. Thoſe Seeds which riſe from the greateſt Depths, are not to be ſown at the loweſt they will bear, eſpecially Wheat, in a Land that has a damp Bottom; for in this Caſe the wet will chill the firſt Roots, which are very tender, and by that Means check the Growth of the Plants: now the Farmer's Buſineſs is not only that the Seeds ſhould ſhoot, but that they ſhould grow well.

Some Differences alſo, with Reſpect to the exact Depths, there are to be obſerved according to the Nature of the Land, as before obſerved, and according to the Manner in which it is laid, whether that be flat or in Ridges, as alſo with Reſpect to the Seaſon of ſowing. In all theſe the Farmer's Reaſon and Judgment are to be his Guides, no general Rule can ſuit every particular Circumſtance that may happen. The Method of giving Directions uſefully, is to lay them down in a middle Way; ſuppoſing the Soil, the Seaſon, and all other Accidents, moderate, neither particularly right, nor particularly unfavourable. This is the Courſe which we have taken. Having added to this the Reaſons that ſhall induce the practical Reader to make the needful Differences, he will ſee in what Caſes he is to vary from the preciſe Rule, and in what Manner; but as to the Degree of differing, that muſt be left to his own Prudence, directed by the Nature of the Circumſtance in his particular Caſe. Farther than this no general Rule can go.

We have every where laid down the beſt Precepts that Experience can furniſh to the Farmer, but we no where demand or adviſe his punctual or exact Adherence to them. The proper End of writing is not to take away the Neceſſity of thinking in thoſe who read, but to lead them to think, and diſpoſe them into a proper Road of doing it to Advantage. Thus, in the preſent Work, we deliver firſt the Reaſons of what we are about to adviſe: and we afterwards give the Directions with as much Care and Punctuality as we are able: but when the Farmer has underſtood the one, and conſider'd the other, let him put them in Practice, according to the Situation, Nature, and Circumſtances of his own Affairs, and of the Land he tills.

CHAP.

CHAP. XLVI.

Of the Quantity of Seed to be ſown in the Common and Drill Huſbandry.

WE have conſidered the Depth at which Seeds are to be ſown, and we have occaſionally mentioned the Differences that may be neceſſary to be regarded in their Quantity, according to their Goodneſs or Degree of Faults: but there remains a very important Queſtion yet to be determined with Reſpect to ſowing, which is, the Quantity of Seed that in any Kind is needful for a certain Quantity of Ground.

This is of great Concern to the Farmer in the firſt Place, becauſe the Price of the Seed in ſome Kinds is a very conſiderable Article, and in the next, becauſe he may hurt his Harveſt, either by ſowing on the Ground a ſmaller Quantity than it would be able to maintain, or a greater. We now come to enquire into the proper Proportion, and ſhall endeavour to guard equally againſt Exceſs and Defect.

It is only according to the new Method of Huſbandry that this can be done, becauſe the new Huſbandry alone is perform'd by Rule: according to the old Methods every thing was left to Uncertainty.

In the uſual Way of ſowing by Hand for Inſtance, according to which ever of the beforementioned Methods it was done, there muſt unavoidably be the greateſt Uncertainty. For one Man's Hand will be larger than another's, and therefore capable of containing more; and yet the Handful is a Handful among the Farmers in ſowing; as the Finger is half a Quarter of a Yard with the Women in meaſuring, whether it be longer or ſhorter.

Beſide this the Seed or Grain of the ſame Kind will be ſometimes larger, and ſometimes ſmaller, and this will make a very great Difference in the Number of Grains in a handful, and the Number is the only proper Conſideration in the Article of ſowing.

Another Inconvenience of ſowing in the common Way by hand is, that if the Field be but indifferently tilled, as is too apt to be the Caſe, ſo that the Earth lie in Clods, and make the Surface conſiſt of Hills and Holes; the Seed Corn, though ſcattered ever ſo equally from the Hand of the Sower, will run off the Surface of theſe Clods and Hills into the Holes; ſo that it will lie on the Field in general very unequally: and in the ſame Manner the Crop will riſe in Cluſters in ſome Places, and defective in others. This is a miſerable Fault, yet it is natural, and according to the common Manner of ſowing univerſal. Thus certain Spots where the Corn riſes, are not able to ſupport ſo many Plants as grow on them, and others are vacant which would very well have fed the Surpluſs. The Benefits of the Field are thus as unequally diſtributed among its Growths, as thoſe of Fortune among Mankind, there is enough for all if it were properly diſtributed, but Millions ſtarve becauſe it is divided unequally.

This is unavoidable in the common Method of ſowing, but it is perfectly remedied in the Drill Huſbandry. The Corn there is ſpread in the Seed juſt as intended, and the Spaces of Ground left vacant are not left ſo at Random, but juſt as they may be moſt uſeful.

A larger Quantity of Seed than is abſolutely needful for the Growth, is alſo neceſſary to be employed in the common Way of ſowing, becauſe ſome of it will be buried too deep, and therefore never ſhoot; and ſome will be left too near the Surface, and therefore will ſhoot very unſucceſsfully. A great deal of that which lies too naked will be alſo eaten by Birds, and other Devourers; ſo that upon all theſe Conſiderations, Reaſon preſcribes to him who will ſow his Grain by Hand in the uſual random Way, that he allow a great deal more than would be abſolutely neceſſary to the Growth.

This is a great Expence if he allows it, and he defrauds himſelf if he denies it; and at beſt the whole is an Uncertainty. We ſhall teach him, by following the Drill Huſbandry in a right Way, to ſave this unneceſſary Charge, always to ſupply his Ground properly, and always to diſtribute his Seed equally.

His Field ſhall have juſt as many Plants on it as it can ſupport, and theſe ſhall have the Advantage of every Particle of his Soil. This is all that can be wiſh'd: this never can be attain'd in the uſual Way of our old Farmers; but however great a Thing it may ſeem to promiſe, it will be perfectly fulfilled by the Drill Huſbandry.

The Seed by this Method is let into Trenches; theſe Trenches are cut at any Diſtance that is found beſt, and the Seed is cover'd in them exactly ſo deep as it has before been found to require for its moſt free and perfect Growth.

As this covering up of the Seeds is not done in an uncertain Way as by the Harrow, but with a perfect Regularity, every Seed is ſure to be cover'd, ſo that none is devour'd by Birds. And finally, the Inſtrument lodges in each Trench exactly the Quantity of Seed that is proper, and no more.

By Means of the Drill the Seeds of all Kinds are lodged in the Earth at proper Depths for their Growth, and out of the Way of Inſects in a great Meaſure, for the greateſt Devourers of this Kind prey near the Surface. The few who creep to any Depth, and devour Seeds, are the Sources of the only Accident to which thoſe ſown in this Manner can be liable; ſo that we may, with this ſmall Exception, provided the Seed have been good, anſwer for the Growth of every Grain.

Here is ſeen the great Neceſſity of that Caution we have before directed the Farmer to uſe in the Choice of his Seed Corn. As the Drill diſtributes only ſo much as is neceſſary, and no more, the utmoſt Care ſhould be taken that this be all good: for by ſo much of it as is naught, by juſt ſo much will the Quantity be too little for the Ground.

Here the ſowing by the Gauge comes into the Farmer's Aſſiſtance.

He has bought his Seed Corn, and he has ſown twenty Grains of it in twenty Holes, and cover'd them equally. They have all the ſame Advantages, let him ſee whether they all come up, or how many are wanting. This will ſhew him the

Value of his Seed: and let him proportion the Quantity he ſows accordingly; allowing ſo much more than what he need to have done if all were good, as will allow for the Defects at that Account.

We do not pretend that this is a punctually exact Rule; for out of every twenty Grains there will not be juſt the ſame Number of good and the ſame of bad; but it comes as near as any Rule in theſe Caſes can do; and what is more to the practical Reader's Purpoſe, it comes as near as it need.

We have obſerved, that the Drill Huſbandry diſpoſes the Seeds in Rows; and the Inſtruments are ſo formed as to ſuit this Practice to the ſeveral Occaſions, according to the Nature of the Plant that is to be rais'd. Thus ſome are diſpoſed in ſingle Rows, ſome in double, in ſome three or four Rows are ſet together. Between theſe Rows there are Spaces of ſix, ſeven, or eight Inches; where there are ſeveral of them; and there are larger Intervals between one Set of Rows, and another Set in this Caſe, and between the ſingle Rows, when they are ſown ſingle.

It will be found by all theſe Trials, that ſuppoſing the Seed of equal Goodneſs, a great deal leſs is requir'd in the Drill Huſbandry than in the common Way. This is not to lead the Reader to ſuppoſe, that ſo many Plants will not be ſupported upon the ſame Ground this Way as the other; indeed a great many more will ripen thus than in the common Method: and this, becauſe of the Regularity with which the Plants grow in this Method; for by the other the Wind will diſpoſe it differently, if it be ever ſo evenly thrown from the Hand; or the Harrow will draw it irregularly in Cluſters in ſome Places from others: beſide thoſe other Diſadvantages we have named from the Irregularity of the Ground. In theſe Cluſters, though many Plants riſe, few come to good, and the vacant Spaces are uſeleſs, becauſe they cannot be tilled while the Crop is growing.

In the other Way the Corn grows regularly, therefore one Stalk does not ſtarve another; and the vacant Spaces being left regularly, are capable of being tilled while the Crop is growing, which is a prodigious Advantage.

Thus it is evident a Piece of Land will ſupport more Plants, when they are thus ſet in a regular Manner, than it can when they are ſcatter'd in a random Way; and that if it raiſe fewer, yet theſe, from the great Perfection in their Growth, produce more in their Kind, becauſe they are better ſupplied with Nouriſhment; for in this Huſbandry every Particle of the Ground is made to ſerve the Plants for their Nouriſhment, as well that which ſupports their Roots immediately, as that which is left vacant between them.

Let the Farmer underſtand this Matter perfectly, for on it depends the Principle of this new Species of Huſbandry. This is a Fact, that fifty Seeds laid together in a Hole in the Place of one, will not produce ſo much as that one, when planted as it ſhould be, and properly nouriſhed. The Number ſtarve one another, and not one of them all come to good: on the contrary, a ſingle Grain of good Wheat, properly ſown and encouraged by tilling the Earth about its Roots while it is growing, will yield a Quantity of Seed at Harveſt Time, greater than we dare mention to thoſe who have not try'd ſuch Experiments. In the common Way a great deal of the Seed is buried without all Hope of Recovery, and a great deal is loſt by various Accidents, as ſaid already, from the other Extream.

The Huſbandmen have never examined, with any Degree of Exactneſs, what is the proper Quantity of Seed for Land; nor do they make any Difference, at leaſt not any great Difference between the Quantity for an Acre of rich, and that for an Acre of poor Ground; though without Queſtion, that Quantity which would be too little for one, would be found too much by a great deal for the other.

It is to no Purpoſe to over-load a poor Soil; nor is there any Practice by which the Farmer more defrauds himſelf, than by not allowing Plants enough to a rich Ground.

CHAP. XLVII.

The Practice in Reſpect of Quantity in different Places.

IN ſome of our Weſtern Counties the Farmers ſow eight Buſhels of Barley on an Acre of Ground. They do not, in this Caſe, conſider the Nature of the Soil, or proportion the Quantity of Seed to it. If it be poor they give it the more Dung; if rich the leſs will ſerve; and in either Caſe the Quantity of Seed is the ſame.

Their common Practice there is to plow the Land only once, then they double dung it, and after this the Seed is ſcatter'd in the random Way by Hand, and harrowed into the Ground

As the Land has now lain ſome time after the plowing, and is grown hard, the Harrow takes but a poor Effect. In all Probability three fourths of the Seed never gets into the Ground, ſo as to grow.

This is their Practice, and the Event is anſwerable to ſuch a Conduct. If the Summer prove dry, the Harveſt ſometimes will not yield half the Quantity of Corn that was ſown: in the moſt favourable Seaſons they ſeldom get above four Quarters to the Acre. This is a miſerable Encreaſe; but they go on ſatisfied: labour is cheap, and they live hard: and ſo they live at all they are contented. What a prodigious Difference is there between this, and the Huſbandry of the new Method. In that the Seed all lies at the ſame Depth, and that is the very Depth Experience has ſhewn to be the moſt favourable to its Growth: none is buried, none is expoſed; therefore no Allowance in the Quantity, is to be made upon thoſe Conſiderations. But as the Fly will damage ſome Seeds, and Froſts may hurt others, a proper Allowance is to be made on thoſe Accounts, and on no other.

Before the Farmer determines his Quantity by the Buſhel or the Pound, as is the common Way, let him examine its Size, for a great many more Seeds will go to the ſame Weight, or the ſame Meaſure, when they are ſmaller, than are requir'd

when they are larger. This will deceive in ſowing by the Drill, as well as by the Hand, if Care be not taken accordingly.

To be ſecure in this Reſpect, let the Farmer weigh an Ounce of the Seed, and count the Number of Grains in that Quantity; then let him weigh a Buſhel, and computing by the Number in the Ounce, he will come near enough to the Number that contains. When the Number of Seeds in a Buſhel is thus obtain'd, they may be portioned by the Rule of Three, to the ſquare Feet in an Acre.

A Standard being firſt eſtabliſhed, upon the before-mentioned Principles, this is a certain Method of giving the right Portion of Seed to any Quantity of Ground. But in this the Farmer is alſo to conſider, at what Diſtance he intends the Rows ſhall ſtand; if he deſigns to plant in ſingle Rows, he is only to conſider what he intends to be the Meaſure of the Intervals; if he deſign in double, treble, or more numerous Rows, he is to compute what will be the Space of his Partitions, as well as of his Intervals; for the more Rows are planted in an Acre, the more Seed will be required.

When the Farmer has thus far conducted himſelf according to Reaſon, not blindly following Cuſtom, let him go a little farther in this rational Way of Computation.

Let him now examine what is the Produce of one middle ſized Plant of the annual Kind; and what is the Produce of the beſt and largeſt of the perennial; for he may aſſure himſelf that a Plant of the perennial Kind will never fail of being brought to this its utmoſt Degree of Perfection by the Drill Huſbandry, connected, as it naturally is, and always ſhould be, in Practice with the Horſehoeing Method.

In all Caſes let the Quantity of Seed, according to the preceding Directions for Computation, be proportioned to the reaſonable Product. Perennials are beſt planted, in general, in ſingle Rows; and moſt of the annual Kinds do beſt in multiplied Rows, two, three, or more, according to their Nature; but in general the beſt Procedure for their Growth to their utmoſt Profit, is in treble Rows, the Rows being ſeven Inches diſtant, and the Intervals between them five Foot.

In many Caſes it is worth while to go over the Ground ſoon after the Plants are come up, and thin them to a proper Number, leaving the moſt thriving. This ſuppoſes the uſing a little more Seed than is abſolutely neceſſary; but it is a very good Method.

In order to the Farmer's being ſet perfectly right in that great Article the Quantity of Seed, let him ſet ſome Rows of the annual Kind thicker than others, and ſee in the End whether they anſwer better or worſe than the reſt.

This is ſending him to his own Experience for his Guide, which is the Courſe we have followed throughout this Work. No Direction is ſo certain; and the beſt Office we can do him is to direct his Experience into the proper Courſe.

CHAP. XLVIII.

Of the Advantages the Drill Huſbandry receives from the Hoe Plow.

TO be more particular on this important Head; Reaſon dictates that the Drill ought to diſtribute more or leſs Seed; or in more expreſs Words, a greater or a ſmaller Number of Seeds in each Trench, in proportion to the Nature of the Plant. This is certainly right: let us ſee then how we can come at the Knowledge on which this Regulation is to depend.

The Nature of the Plant ought to direct in general at what Diſtance the Seeds ſhould be lodged in the Trenches; for this will be in a tolerably regular Manner effected by the Quantity allowed to the Inſtrument: as will be ſeen when we ſpeak of its Structure. Now to determine this, let us obſerve what Space a healthy and vigorous Plant of that Kind, which we are about to ſow, occupies in its natural Growth: when we know this in a tolerable exact Way, we are ſo to fit the Drill that it ſhall leave ſuch a Space between Seed and Seed, ſuppoſing all to be good; or a proportioned Space according to the Degree of their Faults.

We ſhall be ſurpriſed at firſt Sight to ſee a Piece of Land ſown by the Drill, and intended to be horſehoed, becauſe of the great Quantity of vacant Space. We take this at firſt to be unoccupied Land; but in this we err, for on obſerving the Growth of the Plants in the Rows, we ſhall ſee they acquire a Perfection vaſtly greater than thoſe of the ſame Kinds in the common Method of raiſing them; and this is altogether owing to thoſe Spaces. Theſe Intervals we find therefore do, in reality, furniſh the Plants in the Rows with Nouriſhment, tho' at firſt we thought otherwiſe.

In this new Huſbandry we find, at Harveſt Time, that every ſingle Grain of Wheat that has grown well, has produced from twenty to thirty Stalks; whereas, in the common Way of Huſbandry, each Grain generally produces only two or three Stalks. Now if theſe twenty or thirty additional Stalks from each Grain were diſtributed equally in the Intervals, the whole Ground would appear well covered. They are nouriſhed as well in the Rows, as they would be if thus diſtributed along the vacant Ground; therefore whatever be the Appearance, the Effect is equal.

We have counted the Stalks; let us next examine the Ears. Every one of theſe will be found larger and better filled than in the common Way. Therefore as the Number of Stalks made the Growth equal, the Goodneſs of the Ear will make the Produce richer, and the Harveſt more abundant.

This is very plain Reaſoning: it is abſolute Fact, therefore why ſhould not the Farmer receive it as ſuch, and form his Practice accordingly.

In the common random Way of ſowing, the Ground ſeems well covered with Plants, but as all this Number cannot naturally find ſufficient Nouriſhment in the Ground, and it is

in this Way impoſſible to ſupply them better by Means of Tillage, after they are riſen; it follows in Fact, as Reaſon muſt foreſee it would, that a great many of the Plants abſolutely die, and many of the others become ſickly and weak, none ever wearing that healthy Aſpect which is ſeen in thoſe of the other raiſing.

In this new Way all the Plants are healthy and ſtrong, and they are ſupplied, from time to time, with Nouriſhment, by Tillage of the vacant Land between. Their Roots ſpread into that Land, and they are nouriſhed by dividing it. The Strength and rich Produce of theſe, though few in Proportion, might therefore very well make up for the Number of the other ſmall languiſhing and half-nouriſhed Plants. Facts eſtabliſh the Truth of this Account; for upon the faireſt Tryals, and thoſe frequently repeated, it has been found, that of two Pieces of the ſame Land, equal in Size, and alike in every natural Reſpect, the one being cultivated in the old and common Way, and the other ſowed by the Drill, and horſehoed in the Intervals, the Produce of that managed according to the new Method, has been three, four, and ſometimes five Times as great as that of the other.

The Benefit of dreſſing the Land by Tillage, frequently while the Crop is growing, is not confined to the preſent Growth, it extends to the very Hedges. A Hedge of white Thorn that parts two Fields which are dreſs'd in this Manner, will grow four times as faſt as one of the ſame Kind in another Place, and in an equal Number of Years will yield four times as much Wood as the other. This Account has been carried much farther, and perhaps with Truth in other Places, I write what I have ſeen.

This can be owing to nothing but the Advantage there is in ſtirring the Ground. And it is a Proof that this frequent ſtirring is of the utmoſt Benefit to every Growth.

In theſe Hedges, which are within the Reach of this Tillage, the Branches not only grow ſooner to a good Size, but there are more of them. It is exactly the ſame Caſe as with the Corn which we have obſerved riſes with vaſtly more numerous Stalks; and this, beſide ſhewing abundantly the real and great Uſe of this Practice, points out the Advantage it may have beyond the common Uſe of it in Reſpect of Corn.

It is natural to ſay, that Plowing about the Roots of the Hedges muſt cut off a great many of them; and in Effect it does ſo; and it does the ſame with Regard to the Corn, for however little we may, at firſt Thought, imagine it, 'tis certain that the Roots of theſe Rows of Corn do at firſt ſpread themſelves into a great Part of the five Foot Intervals, and by the Aſſiſtance of the Hoe entirely. It is true that the Inſtrument does cut the Roots of the Corn, and of the Shrubs in the Hedge, and that equally; but from this Cutting there reſults nothing but Advantage. The Roots of Trees are like the imaginary Hydra, or the real Polype, they grow the more for cutting; and what is very advantageous, theſe new ones are more proper to draw Nouriſhment than the old. When a Root, whether of Tree or Plant, is cut off, a Number of new ones are produced from it if it be cover'd by Earth, and if that Earth be newly dug they ſpread the more freely and the farther. Thus this cuting of the Roots, in the breaking of the Ground, inſtead of doing any Harm does the greateſt Good, it gives the Plant a thouſand new Mouths to feed by, and it ſpreads Food before them all.

Thus much it has appeared proper to ſay in this Place, with Reſpect to the great Produce of Wheat and other Corn in the Drill Huſbandry, and the principal Cauſe to which it is owing. There are thoſe who drill their Seeds without uſing the Hoe Plow, or leaving Intervals for it, and they ſucceed better than thoſe who follow the old Way entirely; but the two Methods are naturally connected, and they ſhould not be ſeparated. We ſee it is to the Effect of the horſehoeing in the Intervals, that the vaſt Increaſe from the Drill Huſbandry proceeds; and that we have naturally been led to ſay here, will prepare the Reader for that Syſtem which we ſhall, in the ſucceeding Chapters, have Occaſion to treat of in a more particular Manner.

CHAP. XLIX.

Of changing the Seed.

WE have mentioned, under the Article of ſowing, a Thing which it is neceſſary to ſpeak of more largely here; this is, the changeing the Seed, or the ſowing upon a Piece of Land the Seed which has grown in another Place, rather than what has been obtained from its own Crop. We there mentioned the Fact that it is found to be a right Practice, we ſhall here enquire into the Reaſons which ſupport that Practice.

Cuſtom ſpeaks very ſtrongly for the Thing itſelf, and that a Cuſtom not of one Time or Country, but of every Place we know, and of all Times of which we have Account. Flax ripens its Seed very well here, but we import it from FLANDERS for ſowing; and in FRANCE, where every thing in many Places particularly favours the Growth of that Herb, we find they ſtill import their Seed from the ſame Place whence we have it. Our People aſſert, that when they have ventured to ſow the Seed of their own Growth, they have but poor Advantages, compared with thoſe from the Foreign; and the FRENCH, with one Voice, ſay the ſame.

In the ſame Manner many other Seeds are conſtantly imported from different Countries, though they ripen very favourably with us here in the ſame Kinds, and the ſame Advantage is found. Our Farmers from Year to Year, in many Places, change their Seed Corn, and that of other Growths, and they ſay they find the ſame Benefit. If there were no apparent Reaſon for ſuch a Practice, the conſtant Succeſs ſo well ſupported by Evidence, would be ſufficient to engage the prudent Farmer to adhere to it. But there are not wanting Reaſons which explain it; and we ſhall propoſe them to our Farmer, that being inſtructed in the Nature of this Benefit, he may the more firmly ſtick to the Practice which procures it.

In the firſt Place, with reſpect to the conſtantly importing the Seed of certain Plants from particular Countries, there may be this plain Reaſon for the Advantage ariſing from it, that certain Plants thrive better in ſome Climates than in others, and in ſome particular Countries. Where they thrive beſt they will ripen their Seed more perfectly, for that is the great End of their Growth; and many Plants will do this much better in their native Country, than in any other; though they ſeem to agree very well with many others.

A Plant that does not thrive perfectly, will not yield perfect Seeds, and Seeds that are not perfect will not give Plants that are. This is a plain Reaſon why thoſe Plants may be poor which are rais'd from Seeds gathered in a Climate that was not natural to the Kind; and that thoſe may be perfect and fine, though raiſed in another County, that are obtained from Seeds gathered in its own. Every Plant has its Country, and there is this Reaſon for finding where that is. We thus not only ſee the real Benefit that follows this Practice explained, but we are directed to puſh it much farther, and may thereby improve many other Kinds.

Beſide this Difference ariſing from the Climate in which the Seeds have grown, it is evident that they may be altered by the Nature of the Soil in the ſame Country, and that they will be much better having been rais'd on one Kind of Land, than on another. In a poor Soil the Plants grow weak and low, they languiſh as they ſtand, and it is very natural to conclude, that as the Plants are altogether weak, the Seeds are ſo too. Imperfect Plants are not likely to produce perfect Seeds. There is great Reaſon to think the Seeds of ſuch are ſtarved. Plants will not produce ſuch vigorous and good ones, as thoſe would which ſhould be collected from vigorous Plants of the ſame Kind in the ſame Country.

We have been very careful in our Directions to the Farmer about Trees, to chuſe the Seed cautiouſly himſelf, not to get it by Purchaſe. We have adviſed him, on every Occaſion, to gather it from a lively and well-growing Tree. This is founded on Experience, for every Nurſeryman knows, that the Seeds from poor Trees produce poor ones again. As this is a Fact in the larger Productions of this Kind, why ſhould it be doubted in the ſmaller: certainly it is as true of one as the other.

On this Principle Mr. TULL adviſes, that the Seed for any Piece of Ground ſhould be got from a Land ſomewhat richer than itſelf, and from one that is well cultivated. This ſeems to contradict the Doctrine of removing Trees from a poorer Soil to a richer in Nurſeries, and it might well be retorted upon us here, that this Rule ought to hold parallel in one Inſtance as well as another. This ſeems an Argument, and we are aware alſo that the Opinion of many is againſt that we have adopted in this Place; but upon the whole Conſideration it appears, that what this Author adviſes is right. 'Tis the firſt Shoot only that is regarded in Corn, for that is an annual Plant: this is certain to be ſtronger and bolder, from a ſtronger Seed: and this is all the Concern.

From theſe Obſervations the Farmer will eaſily gather the Reaſons for getting his Seed Corn from a better Soil than his own; but we have obſerved, under the Article of ſowing, that it is adviſeable for him to change it merely for the Sake of changing; and in fine theſe, or any ſuch Conſiderations, even this Practice, is not without its Foundation in Reaſon; nor does it want plain Proofs of its Advantage.

Weeds are a great Trouble to the Farmer in his Corn Lands, and there are ſome which naturally love one Soil, and ſome another. The Seeds of ſome of theſe will be mixed among the Corn, and therefore, as they will be ſure to thrive on their favourite Soil, the Farmer when he ſows his own Corn upon the Ground again, lays in a Store of them with it. This is prevented by making an Exchange with another Farmer at ſome Diſtance, who cultivates a different Kind of Land; and there will therefore ariſe a great Benefit to both by the Exchange, ſuppoſing the Corn of each Ground exactly equal in Goodneſs.

Let us ſuppoſe one of theſe Farmers cultivates a light ſandy Soil, and the other a tough clayey one. The Seed Corn from the ſandy Soil is full of the Seeds of the Corn Marygold, and theſe being ſown on the ſame ſandy Ground, would produce that Weed innumerably; but being ſown on Clay they will come to little. In the ſame Manner the Seeds of thoſe Weeds which have a tough Clay, being ſown among the Seed Corn on a light ſandy Land, will ſeldom thrive. Thus ſuppoſing the Seed Corn to be of equal Value, each of the Farmers gets rid of a great Quantity of Weeds by ſowing the Corn rais'd by the other: there is no Diſadvantage attending the Crop itſelf, for Wheat is Wheat, whether it have grown on Clay or in Sand, and it will thrive in either if properly dreſs'd, ſo that the Advantage is certain, and there can be no Harm.

Mr. TULL looking upon this Intent of getting rid of Weeds, as the principal Objection to the ſowing Seed of the ſame Ground, infers, that this changing of Seed will not be neceſſary unleſs for the Sake of getting of better, or more cultivated Ground, becauſe this Method of Culture deſtroys Weeds ſo effectually. It is true that the Horſe-hoeing Huſbandry does deſtroy Weeds; but there is no Reaſon from this to ſay we need not change the Seed, for this Production of Weeds is not the only Miſchief that attends ſowing Corn of the ſame Growth.

We ſhall agree readily with Mr. TULL, that the Grain of Land cultivated by the Drill Plow and Horſehoe, is fairer and finer than that of other Ground; but we ſhall not, for that Reaſon, adviſe the Farmer to ſow it over and over again upon the ſame Piece of Ground; becauſe Cuſtom, ſupported by Experience, ſhews that it is better on many Accounts to change it; neither ſhall we adviſe the Farmer always to chuſe the fineſt looking and biggeſt Grain for Seed. It is a very material Circumſtance in the Drill Huſbandry, that the Seed be nearly of the ſame Size; but it is not needful that it be always large; for the Soundneſs is a more material Article. We find that very ſmall Wheat, provided it be ſound and well conditioned, will produce very large and fine

Plants; and in this there is a plain Advantage to the Farmer, for it goes so much the farther in sowing, as there are more Grains of it in the Measure of a Bushel. It is the Number not the Quantity that he is to regard.

CHAP. L.

Of the supposed Change of Species, and of PATNEY *Barley.*

WE find that Plants of all Kinds degenerate on Soils that are not agreeable to their Natures: they languish or they are starved in the same Manner, whether it be that the Climate, or that the Soil in the same Climate, make the Difference. The Imagination of one Plant's changing into another, because of the Soil not agreeing with it, is idle and foolish. We no longer believe that Wheat can change into Rye, by the Badness of the Ground, nor any of the like Changes of Species; but what we see and know is, that a Plant which continues the same in Kind, will be worse and worse in Quality, as the Soil and Climate are less and less suited to give it Nourishment. This is what we mean by degenerating, and this is what really happens. A Grain of Wheat, however it be managed, will never produce any thing but a Stalk and Ear of Wheat; but when it is sown on a good Soil, and well cultivated, it will raise a great Number of Stalks, all of which shall have full Ears; whereas, when it is rais'd upon a poor and uncultivated Ground, it shall have but one, and that worth nothing.

In the same Manner that REDI proved the Falsity of the Opinion of equivocal Generation, may any one prove that of the Opinion of Wheat degenerating into Rye, which is equally false, though it was at one Time as universally believed as the other.

In the first Instance People saw Maggots in Meat, as soon as it began to stink, and they supposed they were bred from the Meat. That ingenious Italian placed several Pieces of Meat to stink: some of them he set in open Vessels, and others in such as were covered with Gawse, the Flies came to the open Pots, and laid their Eggs upon the Meat, from which Eggs came Maggots, and they turned to Flies like their Parents; but the Flies could not get at the Meat that was covered, so that corrupted as well as the other, but no Maggots bred in it. Hence it was plain, that the Maggots came from the Eggs of the Flies, and were not bred of themselves in the Meat.

In the same Manner the Farmer sows Wheat in his Field, and he sees Rye amongst it, he fancies that some of the Grains of Wheat which he sowed, have produced Rye instead of their own Kind, and this is called degenerating from their Species: but the Truth is, there were Grains of Rye among the Wheat he sowed; and there is no more Reason to wonder. Let him pick a Quantity of Grains of Wheat out of the Ear, and sow them upon as bad Ground as he pleases, the Plants will be poor, but they will be all Wheat. There will be no Rye among them: and let him examine the Wheat he buys for Seed, in Places where he is used to see Rye grow among it, and he will find Grains of Rye in the Parcel. This is the whole Matter: and thus it is that most of the miraculous Accounts we meet with, come to nothing when we examine them with a due Attention.

The whole Case of the Degeneration of Seeds, when strictly examined, amounts to this. The Seeds of the several useful Plants have been brought to their present Condition by Culture: and the Plants which rise from them will answer, in all Respects, while they are well cultivated also, to those which produced them. This Cultivation consists in giving them good Land, dressing it well, and planting them properly in it. 'Twas this rais'd them to their excellent Condition, and this must, and this alone can continue them in it. They are poorer in their State of Nature, and they will, while they are neglected, be returning to that State again. This is called degenerateing; but it is properly a returning to their original Condition: they grow poorer and worse, but they never alter in their Kind.

The great Articles that promote the successful Growth of Plants are two, Heat and Moisture. These differ in various Climates, and in various Soils. The Degree of Heat generally being according to the former, and that of Moisture according to the latter. But we see that a Soil will often act as a Climate, for the Difference of Warmth is great according to its Nature. There may be as much Variation of Heat between a Field of Sand, and another of Clay, in the same County of ENGLAND, as there is between Countries distant by many Degrees.

The Effect of this is plain in what is called the Change of Kind among our Grains.

We talk of PATNEY Barley, otherwise called Rathripe Barley, as if it were of a Kind really different from common Barley. It is the same in Species, but the Difference in its Growth is very great, and by examining this we shall understand a great deal of this whole Matter.

PATNEY is a Town in WILTSHIRE, the Fields about which are of a sandy Soil. Sands, we have shewn, are naturally hot, just as Clays are naturally cold. A Parcel of common Barley being sown in these Fields about PATNEY, will ripen earlier than it would else-where: and the Seed of this Crop will keep this Virtue for three or four Generations.

This Seed, so rais'd from a Parcel of common Barley, is PATNEY Barley, or RATHRIPE Barley. Let it be sown on a light and tolerably warm Soil, and it will ripen a Fortnight or three Weeks sooner than other Barley; and the Grain produced from it will have the same Property for several Successions.

But let this be sown upon a clayey and cold Land, and it will quickly yield common Barley again.

Thus we may, at any Time, make PATNEY Barley out of common Barley; and make common Barley out of PATNEY Barley again.

On this Occasion it may not be improper to add one Caution to the practical Farmer, which is, not to set such a high Value upon this PATNEY Barley as some do. The Change may be

uſeful on particular Occaſions, and for very ſhort Summers, but it is in reality a Change for the worſe. PATNEY Barley is ſhorter liv'd than the common; and it is tenderer, weaker, and worſe. The Novelty firſt recommended it, and Fancy afterwards kept it in Uſe, becauſe of the ſhort Time it is in the Ground: but thoſe who ſow it are, in general, very great Loſers by it.

If this RATHRIPE Barley happen to have a ſmall Froſt after the ſowing, it generally deſtroys it: this is not a common Accident, becauſe it is ſown ſo late: but it may happen; and when it does, the Miſchief is very great: if it have any Check from cold Winds, from an early Drought, or any other Accident, it does not recover as the other, or common Barley will; and at the beſt, if it be brought to a fair Tryal, and a Field of common Barley, and another of this Kind, be ſown on the ſame Day, and have equal Advantages in every Article, the common Barley will yield a much larger Crop, though it be upon the Ground ſomewhat longer. This we have thought proper to add for the Information of the Farmer, who may have been miſled by Opinion, and a popular Practice. There are very few Circumſtances under which it is beſt to ſow the PATNEY Barley; and in all other Caſes the Loſs upon it is certain, and very great.

CHAP. LI.

Of the Effect of Soils on the Growth of Plants.

WE ſee the Soil, in this Caſe, acts in the ſame Manner as a different Climate, changing, as it were, for a Time the Nature of the Grain; and the ſame may be obſerved of all thoſe other Changes which afford the different Kinds of Seed, Wheat and other Corns, diſtinguiſhed by our Farmers under a great Variety of Names.

The Expoſure may alſo act with the Soil in this Caſe. A light ſandy Soil under a tolerable Cover, will ripen any Grain ſooner by a great deal, than a cold tough clayey Land that lies expoſed to the North. The ſame Mountain in the Eaſt produces on the South Side INDIAN Plants, and on the North ſuch as are common to EUROPE. We ſee therefore, by Inſtances at Home and Abroad, that other Cauſes may work in theſe Things the ſame Effects as a Difference of Climate. When we thus underſtand the Nature of theſe Changes, we ſhall not be led into the common Errors about them, which often miſlead the Farmer greatly to his Hurt. This is all the Truth there is in Reſpect of theſe imaginary Changes. The Farmer who reads to learn, and form his Practice according to Reaſon, will therefore know how far he is to regard them, and how far he is to believe thoſe who ſpeak of them. As to theſe leſſer Changes, he ſees to what they are owing; as to thoſe of the varying of one Kind into another, he finds they are falſe. What we have ſaid of the PATNEY Barley may be applied to every other Inſtance, and will be found equally true of all. Though in ſome ſuch a Change is more worth his Regard than in others; becauſe it is more uſeful.

The Flax of FLANDERS is better than the Flax of ENGLAND, as before obſerved. The Seed of FLANDERS Flax, gathered there, and ſown here, will produce as good Flax as there; but the Seed of that Crop which has grown from the FLANDERS Seed in ENGLAND, produces a coarſer Flax, and its Seed a worſe ſtill, till we are neceſſitated to make a Renewal.

It is plain that this is owing to the Difference of Heat and Moiſture, not to the abſolute Difference of the earthy Matter, which is the immediate Nouriſhment. That anſwers for the good Growth as well in ENGLAND as in FLANDERS, as is ſeen in the firſt Crop; but it does not here ariſe to the full Perfection of its forming the Seed, which is the Height of a Plant's perfect Growth; and this is owing to our Country not ſuiting it in Reſpect of Heat and Moiſture.

This appears to be the Caſe on the preſent footing: but perhaps we lay that to the Charge of our Land, which is the Fault of our People. Let them examine ſtrictly upon the Spot, what is the exact Soil on which they raiſe the fineſt Flax in FLANDERS, and what is the Management they give it. Let them fix upon the ſame Soil, and treat it in the ſame Manner here, and perhaps there will then be no Need to ſend thither for Seed. At leaſt the Seed of their Flax will hold good through more Generations, as we ſee is the Caſe in the Inſtance juſt given of the PATNEY Barley; which keeps its Quality many Years, if ſown on Land like that of PATNEY, where it was rais'd, but degenerates quickly into the common Kind, when ſown on any other.

We ſhall enter upon this Subject more largely hereafter, under the Article of Flax; but it was here needful to ſay thus much, producing it as an Inſtance of theſe general Truths.

It is plain from this, and from the many other Inſtances of like Kind mentioned before, that the Nouriſhment of all Plants is the ſame, and that the only Difference is, that ſome Soils abound with that Nouriſhment more than others; and ſome Plants, according to their Nature, drain more of it than others. Therefore there is no Plant but will, according to the Vigour of its Roots, rob ſuch other Plants as are near it: and a Soil which is at one Time proper for one Kind of Growth, will be always fit for it, if kept in the ſame Heart by proper Dreſſings.

This is, in a great Meaſure, contrary to common Opinion, but it is not the leſs true: common Opinion often errs, and in no Reſpect more than this.

On theſe Facts, for they will be found ſuch upon the moſt ſtrict Enquiry, depends that great Improvement of our Huſbandry by the Drill and Horſehoeing Method, which we are about to explain, and which will never be thoroughly underſtood, or rightly practiſed by any who will not thus deeply enquire into the Reaſonings and Experience on which it is founded.

We have abundantly proved that the Matter which nouriſhes all Plants is the ſame; therefore, when a Piece of Ground is exhauſted, by a Wheat Crop, there is no Occaſion to ſow it with ſome other Kind, ſuppoſing it has Nouriſhment for that, although not for Wheat. The better Courſe is to dreſs it properly, and get it into

Heart for Wheat again. This is eaſily done by the new Method of Huſbandry, and that without loſing any Time by a general Fallowing, which is a vaſt Advantage.

We have ſhewn the Farmer how, by a proper Management, a Piece of Ground planted with Coppice Wood, ſhall every Year ſupply him a Felling; and we ſhall ſhew, in the ſame Manner, how a Piece of Ground dedicated to Wheat, or any other Corn, ſhall furniſh him a Crop every Year.

It is very plain that the Advantage found by the Farmers in changing their Crops, is not owing to there being Food of a particular Kind left by one, which is taken by the other; but it is owing to other Cauſes: theſe are the Quantity of the nouriſhing Matter left in the Ground by the firſt Crop, the Quantity required by the next Crop, and the Degree of Benefit given by Tillage.

This muſt be the Caſe, becauſe we ſee that all Kinds of Plants growing in the ſame Soil, take in the ſame Nouriſhment. Upon this Principle we act when we propoſe, inſtead of changing the Crop, to improve the Nature of the Soil by more Tillage; ſo that, inſtead of being in a Condition to ſupport only a poor Crop, it may be able to nouriſh one of the beſt Kind; and this is what we now come to treat of under the Article of Drill Huſbandry, ſo much and ſo deſervedly celebrated.

BOOK VI. PART IV.

Of Drill and Horſehoeing Huſbandry.

CHAP. LII.

Of the Nature of Drill and Horſehoeing Huſbandry.

DRILL Huſbandry and Horſehoeing Huſbandry come very properly to be treated together, becauſe they will never ſucceed ſo well as when they are uſed together. Some Farmers have practiſed the Drill Huſbandry alone, and they have found Advantage from it, as doubtleſs they muſt, becauſe of its ſuperior Benefit to the common Kind; but they might have found much greater Profit in uſing both together. We have, in the preceeding Chapters, informed the Farmer ſo fully concerning the Nature and Growth of Vegetables, that he will underſtand the Manner in which this Huſbandry produces ſuch Excellence in all Kinds of Plants, and we may now therefore proceed to the ſhewing diſtinctly and exactly what it is.

Drill Huſbandry is the Practice of the Garden brought into the Field; and Horſehoeing, in the ſame Manner, is that of the Nurſery employ'd in the Service of Corn. We all know the Practice of the Garden to be better than that of the Field, only more expenſive: there is therefore great Merit in bringing it, ſo far as that can be done, into the Field: and the ſame is exactly the Caſe with the Operations of the Nurſery.

In the Field, Corn is ſcattered at Random, and cover'd at different Depths; in the Garden Seeds are ſet in Trenches, drawn with Regularity, and allowed to the ſame Depth, and that adapted to their Natures. Now in the Drill Huſbandry the ſame is done in the Field. A Plow is uſed to this Purpoſe, that makes Trenches of a proper Depth, according to the Nature of the Seed: the Seeds are ſpread in due Quantity in theſe Trenches, and covered equally in them, ſo that the Practice of the Garden is here exactly brought into the Corn Field, only in a more exact Manner: and what is very remarkable, and very advantageous is, that the plowing, ſowing, and harrowing, is all done at once.

When Corn is ſown in the common Way, there is no meddling with the Ground afterwards, becauſe of its irregular Growth; ſo that the Earth cannot be divided and broken, to give it more Nouriſhment; nor can Weeds be conveniently deſtroyed. But in the Drill Huſbandry there may be left Intervals between the Rows, whether they be ſingle or double, and theſe Intervals, admitting the proper Inſtruments, may be tilled ſo that new Nouriſhment may be given to the Roots, and the Weeds may be perfectly deſtroyed: this is exactly the Practice of the Nurſery. Where the young Trees are planted out into Rows, with Intervals of three Foot or more between them; and thoſe Intervals are, from time to time, dug up. This deſtroys all Weeds that would exhauſt the Ground, and at the ſame Time breaking and dividing it, ſerves to create, as it were, new Nouriſhment.

We have explained already in what Manner the Earth is, by this digging and breaking, prepared to give Paſſage to the Roots; and we have ſhewn how thoſe Roots are multiplied by the cutting them off in the digging. This we have ſhewn in Theory; and the Advantage ſo well known to attend this digging between the Rows in Practice, ſhews that what was there advanced is true.

The ſame Effect which digging takes upon the young Trees in a Nurſery, it will take upon the Crop in a Field, whether that be of Corn, or of whatſoever other Kind; for the Reaſon of the Thing is the ſame in both Caſes, and what is thus founded on Fact will never fail. We ſee therefore here the Practice ſo advantageous in the Nurſery, like that of the Garden, brought into the Corn Field; and ſo well have the Inſtruments been contrived by which it is performed, that the Service of Horſes in drawing them, does as well as the Labour of Men's Hands.

When the two Methods of Drill and Horſehoeing Huſbandry are uſed together, the Crop is planted regularly, and the Ground is tilled while

it

it is growing. The Seeds are covered to a proper Depth, they are proportioned to the Quantity of Ground, and as they come up the Plants are fed in the moſt happy Manner by a continual new Supply from frequent dividing and breaking of the Ground. No more are rais'd upon it than it is able to ſupport, and theſe have the full Advantage of all its Fertility.

This is the Huſbandry according to the new Method: in this all is Regularity, and in the other all is Confuſion and Diſorder.

CHAP. LIII.

Of Drilling.

DRILLING, according to the Account we have given already, is diſpoſing of Seeds regularly in Rows, and covering them with a Quantity of Earth, proportioned to the Depths at which they are found to be moſt advantageouſly planted. We have ſhewn already how that exact Depth is to be found by Experiments made with Gauges; and we ſhall, in a ſucceeding Chapter, deſcribe the Inſtrument by which it is perform'd, with the Aſſiſtance of a Figure. We here treat in general of the Method.

The Drill Plow makes Channels at regular Diſtances, and of proper Depths; it ſpreads the Seeds in thoſe Channels, and it covers them up with Earth. All this is done with great Exactneſs and with great Expedition.

The Seed Box, which is the great Article in this Invention, is a Part of the Inſtrument: it performs the Office of a Hand in ſowing the Corn, but it does it in a much better Manner; for it numbers out the Seeds as it receives them, and diſtributes them in the Trench with the moſt perfect Exactneſs.

The Diſpoſition of Plants in Rows, which is never to be done in Fields any other Way than by drilling, has, beſide the great Advantages already named, this not trivial Benefit, that the Crop comes up together, and 'tis ſcarce poſſible any Weeds can riſe among it. The Corn, or other Growth whatſoever that is ſown, riſes in Lines, and the Weeds naturally are ſeen in the Intervals between them: and however near they ſeldom are exactly in the Line. This anſwers a Purpoſe not to be deſpiſed, for it betrays Weeds at once by their Place, ſo that they may be taken up while young; whereas, in the common Way, they exhauſt a great deal of the Good of the Soil, before their Shape diſcovers them, even if they are taken up afterwards.

Charlock looks very like the Turnip in its firſt riſing; and there are ſeveral Kinds of Graſs which look like the firſt Shoots of Corn. When theſe grow among thoſe Crops, they muſt ſtand till they are grown up to be diſcovered; whereas, when the Seed has been ſown by the Drill, we know that if any thing riſes out of the Line it is not a Part of the Crop, however much it may reſemble it.

We ſee therefore that the Drill Huſbandry at once places the Seeds in ſuch a Manner in the Ground, that they may have the greateſt poſſible Advantage from it; and betrays, at their very firſt ſhooting, thoſe Weeds which would have rob'd it of Part of that Nouriſhment.

It makes Way for the ſtirring and tilling the Ground, during the Time of the Crops growing upon it, which is a vaſt Advantage, and cannot be obtained by any other Method.

By this Means alſo there is an Opportunity of deſtroying the Weeds at any Growth, in the moſt perfect Manner, which could not be done if the Corn, or other Crop, were diſpoſed in any other Manner than in Rows, leaving theſe free Intervals: and thus thoſe uſeleſs Plants which would have exhauſted the Nouriſhment due to the Crop, are torn up and buried in the Earth, and becoming there, as they rot, a Kind of Manure, they ſupply it with new Matter of Nouriſhment inſtead of exhauſting them.

Theſe are the peculiar Characters and Effects of the Drill Huſbandry, which although in itſelf uſeful, yet has no Benefit ſo great as that it makes Way for the other Improvement by Horſehoeing. They are therefore extreamly to blame who uſe one without the other.

CHAP. LIV.

Of Horſehoeing.

THE Advantage which the Earth receives from Tillage are of two Kinds, the deſtroying of Weeds, and the breaking and divideing the Particles of the Soil, in ſuch a Manner that they may afford more Nouriſhment to the uſeful Growths. Theſe Advantages cannot be obtained by any other Method ſo perfectly, as by Horſehoeing; and therefore, in the Nature of the Thing, Horſehoeing Huſbandry is preferable to any other Kind.

The Plow prepares the Ground for a Crop; but it goes no farther, for it cannot be uſed in the common Way of Huſbandry, after the Crop is up: but the Crop may receive greater Benefit from the Tillage of the Land while it is growing, than it could in the Preparation.

When the Earth is well prepared for a Crop, it is broken and rendered looſe, but from this Time it naturally clods together, and grows more compact. Plants require more Nouriſhment when they are grown to ſome Height, than when they are very young; but in this common Practice they have leſs: becauſe the Soil grows worſe and worſe from the Time of ſowing. The Horſehoe breaks and tills the Land while the Crop is growing; and by that Means gives the Plants a new Supply, when they moſt want it.

Plowing and hoeing differ in this more than in the Form or Shape of the Inſtruments with which they are done: a Hoe may anſwer the Uſe of a Plow in breaking the Ground before ſowing; and a Plow may be uſed, as it really is in this Method, to tear up the Weeds while the Crop is upon the Ground. It is in this Period of performing it, that the Work actually differs. As plowing is the preparing Land for the ſowing of a Crop, hoeing is the tilling it when that Crop is growing to Maturity.

If Land be tilled ever ſo well before hand, that will not prevent the Growth of Weeds, for although

although the Roots of all that grew there before were deſtroyed, the Seeds of others are continually brought by the Wind, and the better the Condition of the Land is, the furer they will be to grow.

To the Farmer's Misfortune thoſe Weeds which are moſt troubleſome and miſchievous, have Seeds winged with Down, ſo that they fly to great Diſtances. Of theſe Kinds are Thiſtles, Sow Thiſtles, Coltsfoot, and many others the moſt troubleſome that can infeſt a Crop.

No Care in tilling the Land before hand can defend it againſt theſe; on the contrary, the fitter it is for the Crop, the fitter it is alſo for them: the more firmly they will take Poſſeſſion, and the more quickly they will multiply, therefore ſomething is needed afterwards. The Labour of Weeders is very expenſive, and in the common Way of ſowing they cannot avoid greatly damaging the Crop. When the Seed is drill'd it is eaſy to get between the Rows, even with a large Inſtrument, and the Advantage is evident; and the Work cheaper.

We ſee the Benefit that Herbs receive from a careful tranſplanting, this ariſes from the cutting off the Ends of their Roots, and the placing them among new dug, that is, new tilled Earth. This would be impoſſible in many Caſes; for who could think of tranſplanting a Crop of Corn; but the ſame Advantage is given it when it is planted in regular Rows by the Drill, and the Earth is plowed up between by the Hoe Plow; for in this Caſe the extream Roots are cut off, ſo that the Plant is urged to ſend out more, and there is new tilled Earth for their Reception.

The Advantages ariſing from the hoeing a Garden Crop, in the common Way, with a Hand Hoe, are very great; and theſe are all communicated to a Field of any uſeful Growth, by the Hoe Plow properly uſed, only in a more perfect Manner.

Some People who follow the new Method rob themſelves of half its Benefit, by their Fear of ſetting about it with Spirit. They drill their Seed in Rows a Foot and half diſtant, and then cut up the Earth lightly by a Horſe Hoe between. This is of the Nature of the Garden hoeing, and is of great Advantage, but let it be done properly, and it will be of much greater.

If Wheat be drilled in treble Rows, with Partitions between each Row of ſeven Inches, and there be an Interval of five Foot between every three Rows, and the next three; in this Caſe the Corn itſelf will prevent the Growth of Weeds in the Partitions, and the Ground in the Intervals may be tilled deep and well with the Hoe Plow, and the Crop will be twice as good as in the other Way.

CHAP. LV.

Of the Benefits of deep hoeing.

THE ſhallow turning up the Earth between the near Rows, ſerves as hoeing in Gardens, aſſiſting the preſent Crop, but it has no farther Effect; on the other hand, the deep hoeing in the five Foot Intervals, ſerves in the Place of fallowing, and will, if the Farmer pleaſe to do it well, and depend upon it entirely, anſwer the Purpoſe of Manure; though on many Occaſions it will be worth his while to aſſiſt his Crops by both Means.

The hoeing in this deep and perfect Manner keeps the Earth always moiſt, it diſpoſes it to receive and detain the Dews and ſmall Rains. The more Land is tilled the more freely it receives the Benefit of theſe, and the more ſerviceable it makes them to the Crop. A Piece of hard Land is either dry as a Stone, or poach'd with Wet, for it detains what falls upon it too long; and often this is ſo chill'd that it hurts the Growth. The fine and well tilled Earth, as it receives the Rains and Dews, diſtributes the Wet equally, and as it does double Service, it never can do any Harm.

Experience confirms all that is here ſaid of the Benefit of deep hoeing. If a Piece of poor Ground be ſown with Wheat, when the Plants are yellow and ſickly, let a Part of the Field near them be well hoed in this Manner, and they will be found to revive immediately, as if watered by the moſt kindly Shower, and they will continue to grow and thrive in Proportion as the Practice is continued.

It may be proper to acquaint the Reader here, that if he expect the full Advantage of hoeing, without any Injury or Accident, he muſt prepare the Ground for it by a thorough and good Tillage beforehand: for when the Earth is hard, as it will be when but half tilled, the Hoe Plow often breaks it up, or cracks it among the Rows, if it be carried deep enough; but when the Earth has been put into a good Tilth before, there never comes any Harm of the deepeſt hoeing, for it all crumbles at the Surface about where it is turned.

For the ſame Reaſon that the ſtirring and breaking of the Earth is uſeful in affording Nouriſhment to the Plants that grow near it, the deeper that is perform'd, provided we do not go through the good Soil, the more will be the Advantage: for Plants ſpread their Roots in Breadth and ſend them down in Depth, to a certain Degree at the ſame Time; ſo that the Intervals between two Rows of Corn, by being ſtir'd and broke to eight Inches deep, afford a certain Proportion of Nouriſhment, which the Corn would not otherwiſe have had. If the Earth be ſtir'd and reduced to a proper Degree of Fineneſs, to ſixteen Inches deep, provided it be good and fit for the Nouriſhment of Plants ſo far down, the Conſequence will be, that the Plants in the Rows will receive Nouriſhment from it in a double Proportion. This is the Difference between that ſlight hoeing that is perform'd between the Rows of a Foot and half Diſtance, and the deep hoeing between thoſe where the Interval is five or more Feet.

This ſhews alſo the Propriety of leaving thoſe wide Intervals: and all that will reaſon upon the Matter muſt find, that it will be to their Advantage to have ſuch; but nothing is ſo difficult to conquer as Prejudice: and that is againſt the Practice in this its full Latitude.

A Farmer, when he is directed to plant his Wheat in treble Rows, likes that well enough; but when we name a five Foot Interval between theſe Sets of Rows, he ſtarts at the Thought of loſing ſo much Ground; for ſo Prejudice and the common Opinion, repreſent it to him. But we ſhall ſhew him that there is no Way in which the Ground does ſo much Service, or turns to ſo great Account. In order to be perfectly underſtood, let us firſt enter upon the Conſideration of the Rows.

The Drill Plow may be ſo made as to ſow a great many Rows at a Time, and thoſe at ſmall Diſtances: but this is not the moſt profitable Uſe of it. Some who are, at this Time, introducing the Uſe of Drill Huſbandry without Horſehoeing, are practiſing this, and call it an Improvement; but they ſhould be better inform'd. It was practiſed long before by Mr. Tull, and he gave it up becauſe he found it leſs profitable than the other. Drill Huſbandry and Horſehoeing Huſbandry are two Things, but they ſhould never be ſeparated; and to practiſe them to the beſt Advantage, the Rows that are ſown by the Drill ſhould never be too near.

Some Plants, as we ſhall ſhew hereafter, thrive beſt in ſingle Rows, with large Intervals between, and others do very well with three or four Rows near together, and then a large Interval. In this laſt Caſe the Rows ſhould be about ſeven Inches diſtant from one another, and the Intervals between one Set of them and another, conſiderably broad.

When theſe three or four Rows riſe up to a ſmall Height, they blend in ſuch a Manner at Top, that they make one broad Row together. We call them altogether, in this Caſe, a Row, and when we ſpeak of the Intervals, we mean thoſe between one Set of theſe Rows and another.

Theſe Intervals are to be broader or narrower, according to the Nature of the Plants in the Rows, the largeſt Plants requiring them broadeſt, and receiving moſt Benefit from them.

Every Row of Plants to be horſehoed, muſt have an empty Space at leaſt on one Side, of two Foot and a half broad for the ſmalleſt Kinds, and for all Sorts of Corn it ought to be about five Foot. Smaller Intervals do in Gardening, becauſe the Hand Hoe only is uſed, and does not go deep; but when the Hoe Plow comes, and cuts up to ſuch a Depth, a larger Space is required, becauſe the Roots of the Crop will penetrate farther.

The Farmer will be the more eaſily reconciled to this Practice, when he ſhall be told that although there be five Foot Spaces between the Rows of Wheat in an Acre of Ground, yet the Stalks in thoſe Rows will be more in Number, than there are uſually upon an Acre in the common Way. This may be found by Computation, and this ſhews plainly, that it is an Error to imagine there is any Loſs of Ground by Means of theſe Intervals.

If the Ears were equal in Weight and Goodneſs, the Crop would be equal, becauſe there are the ſame Number one Way and another; but the Ears are finer and better filled in the horſehoeing Way, and therefore the Produce is greater. Theſe are Facts, and this is a Manner of arguing that cannot miſlead.

When theſe Intervals are horſehoed, the Roots of the Crop penetrate quite through them. Therefore the Crop upon a Piece of Ground thus managed, while it ſeems leſs is really greater than in the other Way; and though a great Part of the Land ſeems unoccupied by it, yet every Particle of it is occupied, for as the Roots from the Rows penetrate through the Intervals, they alſo entirely ſpread over or fill thoſe Intervals.

Many Experiments have been made to determine this Matter of the Loſs or Gain by theſe large Intervals, and the Reſult of all is, that the larger the Intervals are left, to a very conſiderable Breadth, the greater always is the Crop.

In the ſame Field wide Intervals and narrow Intervals have been try'd, both without the Aſſiſtance of Dung; and in the other Parts of the Field Dung has been uſed in the common Way without hoeing. The Reſult of ſuch Experiments muſt be concluſive; and it has appeared from theſe, that the dung'd Part without hoeing, did not yield a Crop nearly equal to the hoed Part; and that the hoed Part, where the Intervals were wideſt, yielded the largeſt Crop of all. Therefore hoeing is preferable to Dung on two Accounts, for it coſts leſs, and it produces more; and the wider the Spaces the more Benefit there is from the hoeing. But theſe are only the general Facts, the Farmer is not to determine his Practice by them in every particular Inſtance. We ſhall, on ſome Occaſions, adviſe him to have the Intervals moderate, and on others to uſe Manure with the hoeing.

CHAP. LVI.

Of the different Appearance of Crops.

THE Corn ſown in the common Way often will make a better Appearance at firſt, than that which is drilled and horſehoed; but it declines toward Summer, as the other advances: and though the Seed Corn have been the ſame, and the Land the ſame in every Reſpect, the Crop from the horſehoed is, as obſerved before, vaſtly the larger.

When the Intervals are ſufficiently large, they may be horſehoed ſeveral times while the Crop is growing in the Rows: in this Caſe the Plow may come pretty near the Edges of the Rows the firſt Time, but not ſo near the ſecond, and ſo on, till for the laſt Time it muſt be carry'd only along the Middle. The Reaſon of this is, that it would elſe crack the Ground too much in the Rows, and break off too many of the largeſt Roots, if the Inſtrument run very near, when the Crop was well advanced in Height.

It is always to the Advantage of Plants, that the ſmall Roots ſhould be broke off, but when they are grown to a conſiderable Size they will receive too great a Check by breaking off the larger; therefore only the Middle of the Interval is to be broken up at that Time; and even there, there will be ſmall Roots, which being broken off by the Plow, will ſend out innumerable others into the Earth thus prepared to receive them,

them, and giue them Nouriſhment. Theſe new Roots are full of Mouths for receiving Nouriſhment, as has been ſhewn already, and they find it in Abundance; ſo that Reaſon ſhews how it is that this hoeing only in the Middle of the Interval ſo vaſtly invigorates the Plant.

It is very plain, from repeated Trials, that this Practice of hoeing will give more Nouriſhment to a Crop that has no other Aſſiſtance, than the common Method by Dung; but there is a farther Conſideration ariſing from the Continuance of the Effect, which is of very great Weight, this is, that ſo far is the Land in general from being exhauſted by this Method, that the more ſucceſſive Crops are planted in a Piece of Ground, with wide Intervals, and well hoed, the more able the Land is to maintain them. The laſt Crop is better than any of the former, and this without renewing the Richneſs of the Ground by Dung, or expoſing any Part of it to the Loſs of Time by a Fallow. This hoeing ſerving in the Place of fallowing, and the Intervals, while they are ſupplying the preſent Rows, being preparing for the Support of others.

The Kind need not be chang'd as it muſt be in all other Huſbandry, becauſe of the Ground's growing poorer, for in this Caſe it does not grow poorer, but becomes richer every Year.

When a Piece of Ground is prepared by Dung, it bears Wheat the firſt Year, but the next Crop muſt be of an inferior Kind, becauſe the Soil thus prepared, is growing worſe continually. But on the other hand, the Ground is growing better continually, by this Method of Horſehoeing, and conſequently Wheat may grow on it every Year.

If there were to be any Change of Kind in Fields thus tilled, it would be that the firſt Crop ſhould be the pooreſt, and that the Farmer ſhould riſe to a better and better every Year, till at laſt he come to Wheat: but it may, in general, be prepared for Wheat at firſt, and will continue fit for it throughout.

The wider the Intervals are, the more the Earth may be divided, but as there muſt be a certain Compaſs to allow a Poſſibility of the doing it well, we ſhall ſhew what is the ſmalleſt Space that will allow it. There is not Room to turn two deep clean Furrows in an Interval that is narrower than four Foot eight Inches. If any one ſhould attempt it in a ſmaller Interval, he would throw one of the Furrows, if not both, upon the next Row, and this would do great Damage. Such Plants as grown Saintfoin and the like, that can bear to have the Earth drawn off of them by Harrows may indeed bear this, but even they will be the worſe for it.

The Farmer is, in all Reſpects, to ſuit his Practice to his particular Situation: let him not therefore be tempted by all that is here ſaid, though it be all perfectly true, to follow this Method of horſehoeing againſt all other Meaſures, in every Situation. If he have a dry and brittle Land, on a level Situation, he is beſt of all ſuited for it, for it is with this Land it beſt agrees. If he have tough heavy Clays let him firſt improve them well with Sand, as directed in its Place, and then uſe the Horſehoeing Huſbandry; and if he have Lands upon the ſteep Deſcent of Hills, let him then follow the old Method, at leaſt in ſuch Places; for they are not ſuited to a Practice which requires ſo frequent and ſuch deep Tillage. In common Fields as the Cuſtom and Practice ſtand at preſent, he cannot well follow this Method: but from what we have ſaid on that Head already, and from what Truth and Reaſon ſo plainly point out, we hope we ſhall ſee this Objection to the Horſehoeing Huſbandry daily diminiſh; and Incloſures take the Place of common Fields, in every Part where private Perſons can diſcern their own Intereſt or publick Good promote it.

This Method of Huſbandry has been adopted very much in FRANCE, and has been found, by frequent Trials and the ſtricteſt Computations, to be greatly preferable to the common Practice, and as we ſee the Farmer's Profits ſo low that the Rents in moſt Places are ill paid, and the Farms continually thrown up; is it not greatly to be wiſh'd that a Practice invented in our own Country, ſhould alſo be followed in it, while we ſee others enriched by uſing it, and ourſelves impoveriſhed for want of ſome Improvement in the common Methods? The Legiſlature has interfered lately to introduce the Uſe of Broad Wheels, partly by Penalties on the other Side, and partly by Rewards and Encouragements to thoſe who ſhall uſe them. How much is it to be wiſh'd, that the ſame Interpoſition could be obtained in Reſpect to this Practice, the Conſequence of which muſt be as much more beneficial, as the Importance of being enriched is greater than that of Travelling at Eaſe.

As to the Objection of uſing this Improvement in common Fields, the ſame holds good againſt any other. We have found, of late Years, the Advantage of raiſing what are called the Artificial Graſſes, Saintfoin, Lucerne, and the like. But this can no more be practiſed in common Fields than the Horſehoeing Huſbandry, becauſe People muſt obſerve the ſame Turns of plowing and fallowing with the other Occupiers. All that can be infer'd from this is, that the Interpoſition of the Legiſlature is indeed wanted for the Encouragement of Huſbandry.

Having thus laid down the Advantages of the Drill and of the Horſehoeing Huſbandry, and ſhewn why they ſhould always be uſed together, we ſhall proceed firſt to explain to the Farmer, the Inſtruments that are employ'd in this Practice, and then to the Manner of uſing them for the ſeveral Kinds of Crops. We ſhall firſt convey to the Reader a general Idea of the Drill Box; and afterwards appropriating it to Wheat, the moſt conſiderable Species, we ſhall ſhew it by Deſcription and Figures, as fitted up for Uſe in the Drill Plow; and having thus explained the Manner of ſowing the Corn, we ſhall deſcribe the Hoe Plow, by which the great Advantage of Horſehoeing is to be given to the Crops properly diſpoſed by theſe Inſtruments.

CHAP. LVII.

Of Drill Boxes.

IN the Drill Husbandry an Instrument is us'd for sowing which performs at once the several Operations of opening the Trenches, disposing the Seeds in them, and covering it up when there. The first Part is performed by a Plow, the second by the Drill Box and the third by the Harrow.

The Plow has its Shares so disposed as to cut the Trenches of a proper Depth, at regular Distances, and in a certain Number; the Drill Box disposes the Seeds; and the Harrow covers them. These three Parts compose one Instrument. The Harrow we have occasionally named already, among the other Implements of that Title, and we shall treat of it more largely, as also of the Plow: the present Business is to consider the Structure of the middle Part, the Drill Box, which is the material Article.

The whole Instrument consists of the Plow and Harrow, the Seed Box and Hopper: of these the Seed Box is the great Consideration, this receives the Seed from the Hopper, and delivers it out regularly into the Trenches.

The Mortise is a very material Part of this Implement, and it differs from a common Mortise, in that it is impossible, from its Shape, to fit it with a Tenon, being narrower above, and shorter below; all this will be represented in the Figures.

A Multitude of Words might be used to describe this, and the other Parts of a Drill Box, but the Assistance of the Plates will spare them. It is sufficient if we can convey such an Idea of them that the Farmer will be able to understand them, when we have Occasion to mention them, and the Workman to make them, and to compose the whole: more than this we shall not endeavour.

This Mortise being understood, we shall consider its Use in the Drill Box, and thence the other Parts of that Machine. Let us suppose it a Seed Box for Turnips, it will appear as represented in the Figure under that Name. The Reader will there see the upper and lower Edges, and the Manner in which they are placed over one another. We shew the Top of the Mortise, and the Bottom with the lower Edges.

We have represented, in another Figure, this essential Part, the Mortise cut through and laid open. It is shewn as cut down by its four Corners. If the opposite Sides and Ends were all rais'd up, the Mortise would be formed. A great deal of Care must be taken in making this true, for upon that the Success of the whole Instrument depends.

We have added after this the Mortise of a Wheat Drill, in order to shew that very essential Part the Box, or great Hole, which being larger is best shewn in the Side of that Kind. This Perforation is the Section of a Cylinder that passes through the Mortise.

We have represented in another Figure, the Tongue of the Seed Box, which, in some Degree, resembles the Tongue of the Sound Board of an Organ; but it differs, as is evident, in Shape, in Situation, and in the Manner of its being fixed to the Mortise. The Breadth of this Tongue must be conformed to the Breadth of the Mortise and its Bevel. The Length of it must be such that it will reach lower than just to touch the Bottom of the great Hole.

If the Tongue have too much Play, the Seed is apt to be turned out irregularly.

We have next given the Figure of the Steel Spring in a Turnip Seed Box, which serves both for a Tongue and a Spring.

The Setting Screw is another very material Part of this Instrument, we have therefore represented this plainly and separately. It must be of Iron, and it is to pass through the Hole in the fore End of the Mortise.

We have next represented a Notch of the Spindle, with its Ends near it. And we have next given the fore End of a Wheat Mortise, with its Hole through which the Setting Screw is screwed: and after this the hinder End.

These are the principal Parts of this useful Implement, which the Workman will easily understand; and which we have named and figured, because we shall naturally speak of them in the Course of the Work. And having thus first represented them separate, we have given after them the Wheat Seed Box entire, with all its Parts and Appurtenances: it is there represented as standing on its Bottom; and the Reader will easily distinguish its Cover, which should be of Brass, and the Tongue hanging upon its Axis, the End of the Iron Screw, and the Notches of the Spindle. This Spindle is kept from moving Endways by Wreaths, in the same Manner as the Axis of a Wheel-barrow.

We have next represented the Outside of one half of the Brass Seed Box: and after that one half of a Brass Turnip Seed Box, lying with its Inside uppermost; and afterwards the whole. And we have there given the Spring Cover and the Setting Screw separate: we have afterwards shewn the Counter Screw and the Brass Spindle, in which Place we have represented the Manner of its turning.

In these Figures we have endeavoured to explain to the Farmer what is meant by the Seed Box, and its several Parts, as they may be named separately or entire in the succeeding Chapters. The Workman will also have a general Idea from them, and if he have been accustomed to Things of that Kind, will not find it difficult to execute one from these Parts seen distinctly, and the View of the whole. But as the greatest Nicety and Delicacy is required in the constructing those several Portions, and putting them together; we would advise the Workman who has never made one, to refer himself to the several Cautions and Directions given at large by Mr. TULL, in his Horsehoeing Husbandry; we write to inform the Farmer, not the Mechanick, and must not trespass too far upon the Plan we have laid down to ourselves in the first setting out of our Work. We cannot, within the Compass of our Intention, expatiate farther on the Structure of this

Instru-

Inſtrument, but hope the Figures, which ſave ſo many Words in the Deſcription, will be ſufficient for the Purpoſes to which they were introduced.

CHAP. LVIII.

Of the Wheat Drill, and Turnip Drill.

HAVING, in the preceding Chapter, deſcribed the Nature of the Seed Box, in this Method of Huſbandry, we ſhall here ſhew its Uſe, and the Manner of connecting it with the Plow, Hopper, and Harrow, for the immediate Service in the Field: firſt inſtancing their particular Structure as appropriated to the ſowing of Wheat.

We have repreſented this Inſtrument entire in a Figure; where the Situation of the Seed Box laſt deſcribed, and of the Harrow mentioned in a preceding Chapter, are explained to the Eye, and their Uſes evidently ſhewn.

The Plow repreſented there, is one calculated for drilling Wheat in treble Rows. Theſe Rows are placed at ſeven Inches Diſtance, and the Harrow which moves on its Beams covers the Seed in the ſame Operation.

The Plank repreſented in the Center of the Figure, ſhould be, for this Purpoſe, three Foot and a half long, eight Inches and a half broad, and one Inch and a quarter thick. And its upper and under Surfaces muſt be true Planes. The two Beams of the Plow are to ſtand directly under the Plank, and muſt be held up to it by Screws with Nuts. Theſe are to be two Foot four Inches long, two Inches and three quarters broad, and two Inches and a Quarter deep.

This Plow makes its Channels by Means of three Sheets, which have their Shares and Trunks. The firſt or foremoſt of theſe ſtands under the Middle of the Plank, and to ſhew its proper Structure we have added a Figure of it ſeparately. It is placed obliquely, and pointing forwards in the Plow, that it may be out of the Way of the Funnel. It ſhould be an Inch thick on the upper Part, but the reſt of it need be no more than the Thickneſs of the Share. We have ſingly repreſented alſo a Share lying Bottom upwards; we have alſo repreſented ſeparately one Side of the Trunk, which is a thin Plate of Iron, and is very well made out of the Blade of an old Scythe: this is to be riveted on to one Side of the Sheat. And after this the Trunk entire, which is formed by this Plate, and ſuch another on the oppoſite Side.

After this we have repreſented ſeparately one of the hinder Sheats.

The Figure of this cannot be miſtaken, and its Situation in the Plow is at one of the Beams, as the other is at the other. They are both faſtened into the Beams by their Tenons, which are driven into a Mortiſe made for that Purpoſe, and faſtened by a Pin paſſing through the Beam.

The Figure will ſhew the Workman how he is to make theſe, but it may be proper to caution him not to make the Tenons acroſs the Grain of the Wood; but to chuſe for this Purpoſe a crooked Piece of Timber.

Theſe Things being underſtood, of the Parts and their Structure, we may continue the Conſideration of the Plow as repreſented together. The fore Sheat being fixed up at equal Diſtance from each End of the Plank, and as near as can be to its hinder Edges, the Funnel has Room to ſtand with the fore Side of its Hole to make one Surface with the Back of the Sheat: and the hinder Part of the Trunk does not reach the Edge of the Plank. The Fore-Standard muſt ſtand perpendicular to the Plank acroſs the Tenon of the Sheat.

This Standard being thus cloſe to the fore Side of the fore Hopper, there muſt be ſo much Room between it and the Hole of the Funnel, that the Seed may drop from the Seed Box into the Middle of this Hole.

The two hinder Sheats muſt be placed at equal Diſtance from the Sides of the Beams, and ſo near to their hinder Ends, that there may be Room to make the Funnels in them, and their Tenons to come up between their reſpective Funnels and Standards; theſe Standards alſo muſt be ſet perpendicular to the Beams. The Beams muſt be placed at ſuch Diſtance from one another, that the Shares may be fifteen Inches aſunder, from the Inſide of one to the Outſide of the other; and the Shares muſt be all parallel to one another, and to the Beams.

This being the Structure of the Drill Plow, the Channel or Trench that is made by the Middle, or fore Share or Sheat, being at an equal Diſtance from the two hinder Sheats, is filled up, and the Seed is covered in it by them; and the Seed in the Trenches made by the two hinder Sheats, is covered by the Harrow, which is faſtened to the Beams of the Plow, and has two Tines placed juſt at a right Diſtance for that Purpoſe: of this we need not give a farther Deſcription. Its Figure and Situation behind the Plow repreſent it ſufficiently, and we have had Occaſion to deſcribe it before, among the other Kinds of Harrows.

The Funnel riſes two Inches at the Edges from the Surface of the Plank, and is five Inches ſquare at the Top; and its Hole at the Bottom is continued quite through the Plank, into the Trunk that is underneath. This Hole is ſquare. Its Opening for Wheat and other Grain, is to be three quarters of an Inch; but when Peaſe, Oats, or other large Seeds, it may be made an Inch ſquare, and it is to be a little wider at the Bottom than the Top. The other Funnels are to be made exactly like this. They cannot be ſo deep, becauſe they are cut in the very Beams, but their Width at Top is encreaſed by adding on each Side a Piece of Wood, ſo that they are each an Inch and quarter wider than the Breadth of the Beam. The upper or fore Side of theſe Trenches muſt not riſe ſo ſlanting as the others, becauſe that would bring them too near the Tenons of the Sheats.

Acroſs the Plank of this Plow, near its Edges, there lie two Pieces of Wood: theſe are each eleven Inches long, two Inches broad, and two thick. They are faſtened by Screws and Nuts, and ſtand parallel to the other Beams. Each

of theſe have a double Standard or Fork, perpendicular to the Plank, and by theſe Standards the fore Hopper is drawn and guided.

Having thus far examined the Nature and Make of the Plow itſelf, which could not be ſo well comprehended in a Figure, if drawn entire with its Hopper, we have repreſented it again in that perfect Condition, fully fitted up, and ready for Work. In this and the other Figure ſeen together, all the Parts may be very plainly diſtinguiſhed.

The fore Standard, which riſes from the Front of the Plank, is to be two Foot long. Its Breadth is to be two Inches in the narroweſt Part, and it is to be half an Inch thick in the thinneſt, and two Inches at its Shoulders above the Plank. We have repreſented it ſeparately, and it will be ſo ſeen in what Manner it is pinn'd through the Plank before the Funnel. It holds the fore Hopper from turning upon the Spindle. It is put through a Carrier like that of a Door Latch, which is nailed on the upper Part of the fore Side of the fore Hopper. In this the Standard has Room to play, or move Sideways, that either Wheel may riſe up.

We have repreſented ſeparately alſo a hinder Standard, which being placed perpendicularly in the Beam, is fixed in a Mortiſe, and pin'd into the Beam. It has a Shoulder behind, another before, and a third on its Outſide, and theſe ſerve inſtead of Braces to keep it from moving backwards, forwards, or outwards. This is two Foot four Inches long, two Inches broad, and an Inch thick.

The two hinder Standards are made juſt alike except for their oppoſite Situation, their Uſe is to guide, draw, and hold up the hinder Hoppers, which are repreſented in the Figure where this Plow is ſhewn compleat, in their Places. They are to ſtand upright, and in the Middle of the Beams, and at ſuch Diſtance before the Funnels, that when the fore Side of the Hopper, by its whole Length, bears againſt the hinder Surface of the Standards, the Seed may drop into the Middle of both Funnels.

The Shafts, or Limbers, are repreſented in both Figures, they are to be fix'd down to the Plank, each by two Screws and Nuts, and they are kept at a due Diſtance by the croſs Bar, which runs from one of them to the other, at a ſmall Diſtance from the Plank. Theſe Shafts muſt be ſo placed that the Path of the Horſe is ſtrait with the Center of the Plow, and then it will follow in a direct Line.

The Uſe of the Trunks in this Inſtrument is for making the Channels narrow. Without Trunks theſe Channels muſt be made with Ground Wreſts, which ſpread the Sides of them wide; but theſe Trunks make them narrow of whatever Depth.

We have repreſented ſeparately one End of a hinder Hopper laid open, the middle Part is cut out to give a cloſer Sight of the Plow and fore Hopper. The whole Hopper is repreſented alſo ſeparate and entire; as alſo a Hopper with its Standard, Spindle, and Seed Box. By theſe Figures the entire Mechaniſm of this Inſtrument will be underſtood. At the Bottom is ſeen one End of the Spindle paſſing through the Hopper and Seed Box.

The bottom Board of this Hopper, which holds the Braſs Seed Box, ſhould be four Inches broad, and full half an Inch thick. And at each End it muſt be a quarter of an Inch longer than the Seed Box. We have alſo repreſented ſeparately the two Sorts of Wreaths, which are ſcrewed upon the Spindle to keep it from moving towards either End, as well as to hold the Hoppers in their Places, one Kind may be made of Wood, the other muſt be of Braſs, and is greatly preferable in all Reſpects.

When the Plow is all together, as in the Figure where it is repreſented entire, the fore Hopper ſhews itſelf very diſtinctly; it is ſeen with its Seed Box ſtanding on the fore Funnel: this is larger than the hinder Hoppers, but there is no more than the ſame Quantity of Seed to be put into it, when it is uſed.

As to the Wheels of this Plow, the Diameter of the fore ones is to be thirty Inches, and that of the hinder ones twenty-two; and their Spokes are to be made ſtrait, ſo that they are not hollowed in the Manner of other Wheels.

Thus have we repreſented to the Eye this complicated Inſtrument, and explained its Parts by a few plain Words. A Volume might be written upon it; but by this the Farmer will underſtand enough of its Operations, and the Plow-wright of its Form.

This is the Drill for Wheat, and the little Variations neceſſary to be made in it for other Seeds will eaſily be comprehended. However, we have added the Figure of the Drill Plow for Turnips, that the general Difference may be ſeen. The Funnel, Sheat, Share, and Trunk, which are the eſſential Parts for the Work, are the ſame as in the Wheat Drill already deſcribed, with very little Variation; and the Inſtrument is the leſs complicated, becauſe it is to ſow but one Row, not three at a Time, as is done in Wheat, which made the Neceſſity of three Hoppers, and, in a Manner, of a treble Apparatus, which is in this Caſe ſingle.

He who underſtands the more complicated Kind, will find no Difficulty in comprehending every Part of this, the principal Difference of which is, that it is ſingle. The Shafts in this are to be light, and the Bar is to be about three Inches diſtant from the Plank. The Plank ſhould be two Foot and an Inch long, five Inches broad, and an Inch and quarter thick; and the two Pair of Standards placed into the Plank, with Shoulders above, are to be thirteen Inches high above it. The Beam of the Plow is to be two Foot two Inches and a half long, four Inches broad, and two Inches thick. The Funnel is to be two Inches deep, and four Inches ſquare at the Top. The Harrow follows in its Place, and the Tines are made of Wood: and they are to ſtand eight Inches aſunder at their Points, and ſix Inches and a quarter at their upper Parts, juſt under the Harrow Head. The Hopper of the Turnip Drill conſiſts of a Box placed in to the Middle of a Carriage, we have repreſented this ſeparate, that its Figure may be more diſtinctly underſtood, and afterwards the Carriage in the Middle of which it is placed.

The

The Circles of the Wheels of this Hopper go five and twenty Inches aſunder.

The double Standards are uſed on a Level, and not otherwiſe. We have therefore added another Figure of the Turnip Drill Plow, entire and fit for working without them.

CHAP. LIX.

Of the Hoe Plow.

WE are aware that this Deſcription of the Inſtruments will appear tedious to ſome, and that it will be ſaid, as there are People enough who know how to make them, why ſhould their Parts be deſcribed here. Others have beſtowed many Sheets upon them, where we have compriſed what we thought needful to be ſaid in a few Pages. But ſomething beſide the bare Figures we thought neceſſary, becauſe we would have every Farmer entertain at leaſt a general Knowledge of their Nature; and becauſe we otherwiſe ſhould not have been underſtood in the ſucceeding Chapters, when we come to name their Parts, in treating of the Manner of uſing them.

We have gone through the moſt complicated, and longeſt Detail, in the Article of the Drills, the Reader will give us his Indulgence while we explain, in very few Words, the Hoe Plow, or Horſehoe, which is an Inſtrument much leſs compounded, and much eaſier underſtood.

We have given a Figure of the Hoe Plow entire, and the Reader who is already acquainted with the Structure of a common Plow, and the Names and Uſes of its ſeveral Parts, will be at no Loſs to underſtand this.

The Beam and Tail are very like thoſe of the common Plow. Indeed the Reſemblance is ſo great, that the Beam of a common Plow being cut off, and ſcrewed up to the Plank of this, with its Shafts tight, make a good Hoe Plow.

But to make a Hoe Plow perfectly and properly, it is better to ſet about it entire, and for that ſingle Purpoſe. The Share, from its Tail to the fore Part of its Socket, ſhould be two Foot and one Inch long, and from thence to the End of the Point, ten Inches and a half: this is the proper Meaſure of its under Side. The Length of the Plank ſhould be two Foot ſeven Inches and a half; it ſhould be nine Inches broad, and two and a half thick. The Shafts are to be ſcrew'd to the Plank, in the ſame Manner with the Beam. And the Draw Pin, whoſe Nut is ſeen in the Center of the Plank, is to have a Crook underneath, to which one of the Links of the ſhort Chain of the Whipper is faſtened. The under Surface of the Shafts runs on a Level with the Plank, and they are to crook outwards till they come within a Foot of the Chain, theſe Shafts muſt be ſtrong and well made. The Notches in the Ends of the Whipper, ſerve to faſten the Traces of the Horſes. And the ſhorter the Shafts are from the Bar the better, ſo they are ſufficient in Length for their Purpoſe.

This Plow is a very plain and very excellent Inſtrument. It is ſet to go deeper or ſhallower, by changing the Links of the Chain of the Shafts which lay hold of the Crook. This has the ſame Effect in the Hoe Plow, as the changeing the Pins to different Holes of the Crow Staves in a common Plow. We have repreſented ſeparately the Beam, with its Mortiſe and Holes; and the Plank which, by its Holes and dotted Lines, ſhews the different Manner of placing the Beam. The four Holes near the Ends, are for ſcrewing down the Shafts.

There are uſually nine Holes in the Plank, for changing this Situation of the Beam, that the Plow may fallow in a right Path. The Holder may alſo make ſome Alteration in the going of the Plow by the Handles.

After thus repreſenting the Inſtrument, we have ſhewn it at Work, where the Manner of fixing the Horſes is ſeen. This Inſtrument therefore being, in this Manner, explained, we ſhall enter upon its Uſe, together with that of the Drills before deſcribed; that is, on the Practice of Drill and Horſehoeing Huſbandry for the Service of which theſe Inſtruments have been invented.

BOOK VI. PART VI.

The Benefit of Drill and Horſehoeing Huſbandry, ſhewn in three Sorts of Crops.

CHAP. LX.

Of raiſing Turnips by the Drill and Horſehoeing Huſbandry.

AS we have now laid down the Theory of the Drill and Horſehoeing Huſbandry, and deſcribed the Inſtruments by which it is to be performed, we ſhall in this, and the two ſucceeding Chapters, reduce that Theory to Practice, and ſhew the Uſe of the Inſtruments in the Field.

We ſhall chuſe for the Inſtances of the ſeveral Methods of practiſing it, Turnips, Wheat, and Saintfoin: the moſt uſeful Root, the moſt valuable Corn, and the fineſt of the artificial Graſſes.

Each of theſe we ſhall mention ſeparately, and the Reader will recollect that, according to the Courſe laid down in our Plan, they are to be treated of generally in a ſucceeding Part of our Work,

Work, among other Roots, Corn, and Graſſes, they are here conſidered only as Inſtances by which to ſhew the Practice of this particular Species of Huſbandry and its Excellence.

Turnips are of ſeveral Kinds, and diſtinguiſhed by different Names, according to their Shape and Colour, but the principal Sorts that the Farmer has to do with, are the common round Turnip, the long, or Suffolk Turnip, and the yellow Turnip.

He plants theſe for the Food of his Cattle; and though it is but of late that this Root is got generally into the Field, yet the Advantage of cultivating it is ſo very great, and ſo very well known, that there is no Article in the Farmer's Profeſſion better worth his Regard; and there is nothing in which he may have more Benefit from the Drill and Horſehoeing Huſbandry.

Turnips thrive beſt in a light warm Soil: for this Reaſon they particularly fall in the Way of this Kind of Huſbandry, becauſe it is on ſuch Land it is beſt practiſed. The common Method is to allow two Pounds of Seed to an Acre, and to ſprinkle it on with the Hand.

They are ſown at two Seaſons. In Spring to produce Seed the ſame Year; and at Midſummer for the Food of Cattle in Winter.

Thoſe ſown for Seed are few in Compariſon of the others. A Part of the Seed is uſed for ſowing again, and the reſt is mixed with Coleſeed to make Oil.

In order to the Midſummer ſowing, the Land is to be plowed in May, and twyfallowed in June to make it fine, the Seed is then to be harrowed in; and thus they are raiſed in the common Method, and are ready for the Cattle in the Depth of Winter, and the Beginning of Spring.

In this Way of raiſing them they are very liable to be devoured by the Fly, and the Ground is to be often ſown over again.

When they come up too thick the Practice is to thin them with a Hand Hoe.

This is the whole of the Farmer's Practice in the common Way for raiſing of Turnips, but this is ſubject to many Inconveniences: we ſhall now ſhew the Method by the Drill and Horſehoe, which will be the better underſtood, and its Advantages the plainer ſeen, after this Account of the raiſing them in the other Way.

That the Farmer who ſhall try this Method upon Turnips may give it fair play, let him firſt fix upon a Field that has a proper Soil. The moſt favourable Land of all is ſuch as is light, ſandy, warm, and a little moiſt. On the contrary the worſt is Chalk; but with good Culture they may be raiſed any where. If the Soil be ſhallow neither Turnips, Carrots, nor any other large-rooted Plants, will ſucceed ſo well as when it is deeper: and as the Soil nouriſhes Plants in a great Degree, according to the Care that is taken to break and divide it: this is another Reaſon why Turnips have a great and particular Advantage from this Method, becauſe none ſtirs or breaks the Earth ſo thoroughly, or ſo deeply.

For this Reaſon, when a Piece of Ground is intended for Turnips, of whatſoever Kind it be, it ſhould be firſt plowed up as deep as poſſible, and then, as thoroughly as poſſible, broken and divided to fit it for their Nouriſhment. If the Soil be in its own Nature light, this will do; but if it be a tough and heavy Piece of Land, other Methods are to be uſed to reduce it to Fineneſs; for unleſs that be done effectually, ſo that it may be kept fine, the Turnip will never arrive in it at its due Perfection.

Thoſe who would have Tillage anſwer the Place of Manures, will recommend nothing more in this Caſe, than the thorough breaking and dividing the Land by working; but we do not write to ſerve a Syſtem, but to ſerve the Farmer. Therefore although we are, in this Place, recommending the Horſehoeing Huſbandry, and propoſing the Excellence of it in raiſing of Turnips, yet we ſhall adviſe the Huſbandman to add, in Caſe of this tough Soil, the Benefit of Manures.

Let him lay on theſe in their proper Kinds, and in the due Quantities, as has been directed at large in the Account of Manures in a preceding Part of this Work. When he has, by this Means, converted a heavy Soil into a light one by the due Uſe of Manures, let him go to work upon it for Turnips with the Horſehoing Tools.

To give an Inſtance of what we mean. Suppoſe a Farmer has a Neceſſity of raiſing Turnips, and has nothing but a clayey Soil: in this Caſe Turnips will not thrive upon it, becauſe it is cold and tough. Let him throw on good River Sand, this will make it a Kind of Loam, in which State it will be lighter and dryer; and when he has made this Change in it, let him go to work and prepare it for his Turnips. The Horſehoeing Huſbandry, with the Aſſiſtance of this Manure, will produce them in great Perfection. Whereas it would have done it but poorly without.

There may be other Soils which have a Neceſſity of other Kinds of Manures, according to what has been before written on theſe Subjects, and in theſe Caſes let the Farmer act juſt as in the preſent. Let him firſt improve his Ground by the neceſſary Manures, and then proceed to the preparing it for this particular Growth. The Succeſs of his Turnips will make ample Amends for all his Trouble and Expence, and ſo he will find it in every other Kind.

For this particular Article, if his Land be light, it is fit for the Growth: if it be not, he muſt endeavour to make it light by Manures and Tillage; and if he have not Convenience of getting as much Manure as he could wiſh, he muſt make up the Deficiency by ſo much the more Tillage.

The Seaſon of ſowing Turnips for the Winter Service, is properly from the End of May, to the Beginning of August. The warmer the Soil the later they may be ſown; but in ſuch as want that Advantage, it is beſt to be early.

The great Diſadvantage of chalky Soils for Turnips is, that they grow ſlowly: and this, in their firſt Stage, is very deſtructive. The Turnip, before it gets its rough Leaves, is the Prey to many Inſects; and as it is longer in chalky Soils than in others before it gets them, there is the more Danger. This Plant grows much quicker in the new Method than in the old, and there-

therefore it is one of thoſe that have the moſt Benefits from it.

The ſandy Soils being warm make the Turnips grow faſt, ſo that they are ſooner out of this Danger: and the Horſehoeing makes the Earth imbibe and receive the Dews ſo plentifully, that there never wants Moiſture to the Roots, ſo that they are always in a Condition of growing with Vigour.

In the new Method an Ounce of Seed ſows as much Land as a Pound in the ordinary Way. In that Way the Turnips riſing at Random are, in a great Meaſure, to be cut up, but in this all the Seed that is ſown is for good.

CHAP. LXI.

Of the Diſpoſition of a Turnip Crop.

THE Turnip being a large-rooted and ſtrong Plant, ſhould be ſowed by the Drill Plow in ſingle Rows. We have ſhewn the Inſtrument which is to perform this; and Experience proves that the beſt Diſtance for theſe Rows is ſix Feet aſunder. Theſe large Intervals will appear a great deal of waſte Ground, but we have ſhewn already that the Turnips have the Advantage of it all; and they will evidence it by their Growth much better than we can by Words.

Turnips have been tried in double Rows, but they do not ſucceed ſo well, Mr. Tull made the Experiment, but found it unſucceſsful. He alſo ſowed them in ſingle Rows, with only three Foot Intervals, but that did not anſwer ſo well. He found that a Field ſowed thus, produced a much larger Quantity of Turnips than a neighbouring one of the ſame Extent, which was ſown and hoed in the uſual Way; but its Produce was not comparable to that of the ſingle Rows, with ſix Foot Intervals. When theſe Intervals are well wrought by the Horſehoe, and that to a good Depth, the Plants grow in a ſurpriſing Manner, and never ſuffer by Drought; the breaking of the Earth making ſo fit for the Reception of the Dews, that it is always moiſt.

In Languedoc they have only four Foot Intervals between their Rows of Vines in their Vineyards, and they break the Earth between with a Hoe Plow drawn by Oxen. This has led them in that Country, where they very much uſe the Horſehoeing Huſbandry at preſent, to make the Intervals of the ſame Breadth: but their Turnips, by their own Account, have not come up nearly to the Size and Perfection of thoſe raiſed in England, with ſix Foot Intervals.

According as the Seaſon promiſes to be dry or wet after the drilling, the Seeds ſhould be let into the Ground at a greater or leſſer Depth. When there follow Showers the Seed will grow, though but juſt covered with Mould; but in a dry Seaſon nothing aſſiſts the Shooting ſo much as the Seeds lying at ſome Depth, becauſe there it is in the Way of ſome Moiſture, that Part of the Earth never being ſo burnt up as the Surface.

A great Advantage of the Drill Method is, that the Seeds may be let into the Trenches at different Depths, ſo that whatever be the Seaſon ſome will be ſure to riſe. When the Seeds are thus lodged alternately ſhallower and deeper, it is always found that if there follow Rains, the ſhallow Seed is the firſt that ſhoots; but if it be dry Weather, that is up firſt which lies the deepeſt.

There is a great Advantage in having two Shootings of the Turnips in the ſame Field: we have obſerved that no Plant is ſo liable to Accidents when young, and by this Means, if one Crop ſhould be deſtroyed, there is another ſafe perhaps, without the Trouble of a freſh ſowing.

The ſame Advantage may alſo be obtained by ſowing a Mixture of old and new Seed, for the old is much longer before it comes up than the new.

The Farmer who underſtands the Nature of the Inſect that devours the young Turnips, will very well comprehend this Advantage; but to others it will need ſome Explanation. The Creature that does the Miſchief is a ſmall Fly. This comes in Clouds in innumerable Multitudes, and wherever the Swarm ſettle they eat away down to the Root, and deſtroy the Produce. When they have done this Miſchief they go away, and it is perfect Chance whether they come again juſt at the riſing of the ſecond Crop.

It is only while the Turnip is very young that it is liable to this Miſchief, and there is no Probability that two Swarms of theſe Creatures ſhould come each juſt at the Time when there is the Danger. If they keep away till the rough Leaves come the Crop is ſafe; and this, according to the preſent Method, is in a very little Time. The two Seed Leaves which are ſmooth, thick, and juicy, are the Food of theſe Flies, and no other Part.

When the Seaſon is favourable, when all the Seeds have ſhot, and no Miſchief has been done by Inſects, the Number of Plants will be too great. Precaution has been uſed to ſow more than need grow, becauſe it is natural to ſuppoſe ſome will be loſt; but when all riſe they muſt be thin'd.

The ſooner this is done the better. The Method is to pull up the worſt looking Shoots, and moſt where they ſtand thickeſt; it is idle to let theſe ſtand to exhauſt the Earth firſt, ſo that the earlier they are deſtroyed the better.

As to the Quantity to be pulled up; that will be determined by the Number that have riſen. The Turnips that are left ſhould ſtand at about ten Inches Diſtance. They will thus look thin while they are young; but they will ſoon ſeem thicker by their Growth.

When the Turnips have got ſome Bigneſs in Leaf, the Hoe Plow is to be brought in to plow up the Intervals. They may be wrought two and two if the Crop grow well. This gives them their Food from the new broken Earth moderately, from time to time, and it is better than to give them a great deal at once, and then leave them a great while without any Refreſhment. This alternate plowing of the Intervals is beſt for thoſe Plants, of whatever Kind, that are ſowed in ſingle Rows. But with all its Convenience and Advantage, it does not deſtroy the Weeds ſo well as plowing all in a regular Manner,

ner, and at once. Therefore, when the Weeds are very rank that Method is preferable.

CHAP. LXII.

Directions for horſehoeing of Turnips.

IT is a great Advantage to make the Plow come as near the Rows as may be, without damageing them: and this may be done much cloſer when they are young than afterwards; when they are hoe plowed afterwards, and ſome Earth is neceſſarily left near the Rows unbroken by the Plow, a Man ſhould be employed to go and turn that by Hand, with a Hook or ſome other Inſtrument. The looſening of the reſt of the Ground will make this break ſo eaſily, that a good Labourer will do a great deal in a Day, and 'tis a vaſt Advantage to the Crop; this is a much better Method than to bring the Hoe Plow near them when large.

For many Plants, when drilled in ſingle Rows, the Method of working the Intervals alternately is very right, and where the Weeds do not make the other Method neceſſary, it is very eligible. Two Plowings in this Manner are only the Expence of one, and the Benefit is commonly ſufficient. The Plant that has abundant Nouriſhment from one Side, may diſpenſe with its being more ſparing on the other; and there are other Reaſons yet for this Practice. If the Plow, by coming very near the Plants, have cut and broke too many of their large Roots, 'tis only on one Side, and thoſe on the other Side will take in a ſufficient Supply of Nouriſhment, till new ones are puſhed there in the Place of others. The Ground being firmer, we may, in that Caſe, carry the Plow nearer to the Turneps without Danger of looſening them; and finally, when the Crop is large the Plow goes more readily to the Supply of firſt one Parcel and then another; if all have leſs Nouriſhment at a Time none are long neglected.

While the Turnips are ſmall, great Care muſt be taken that a Furrow is not left open near them, becauſe the Earth about them would become too dry; but when they have three Months Growth, and the Seaſon is advanced to Autumn, there is no more Hazard from this Article, becauſe not only they are grown ſtronger, but the Earth naturally becomes more moiſt. When the Froſts ſet in, the ſame Caution ſhould be obſerved, not to leave a Furrow open near them, leſt they ſhould, by that Means, be put more in the Power of the Weather.

The Seaſon in which they are ſowed will, in ſome Meaſure, determine whether the Intervals are to be plowed alternately or otherwiſe. If the Turnips have been ſown late this Method will do, but if early the Weeds will grow faſt, and the other Method of plowing them all in a regular Manner will be neceſſary.

It is ſurpriſing to what a Bigneſs Turnips will grow, by this Method of Culture. Seven or eight Pound Weight is not an uncommon Thing for a whole Field, one with another; and in very good Land, when the whole Practice has been rightly conducted, 'tis common to ſee them of fifteen Pound Weight or more ſingly. The Produce of an Acre of Ground thus planted with Turnips in ſingle Rows, with ſix Foot Intervals, is eaſily computed, and it will aſtoniſh any one not uſed to ſee the Effects of the Horſehoeing Huſbandry.

The great Uſe of theſe Field Turnips is to ſupply the Cattle with Food in the Depth of Winter and in Spring, till the Graſs gets ſome Strength. For this Purpoſe, as they are only pulled up as they are wanted, they often muſt ſtand till the Seaſon of ſowing Corn is advanced too far, or is abſolutely over. This is a very reaſonable, and a very great Objection againſt the Turnip in the common Way, but in this Method of the Horſehoeing Huſbandry it is none. The Ground in the Intervals may be ſown: the Turnips may ſtand as they are moſt uſeful, and they will get nothing but freſh Advantage from the repeated Tillage of the Ground in the Intervals.

The very plowing for the Sake of the Turnips, has kept the Intervals in excellent Order, and they may be ſown in the Middle with Corn in treble Rows, at the Diſtance of ſeven Inches, Row from Row; in which Caſe there will be ſufficiently broad Intervals between them, which, when the Turnips are all taken up, will be ready for plowing for the Nouriſhment of the Corn.

Cows are very fond of Turnips, and they encreaſe their Milk. Sheep alſo eat them very greedily, and they are a wholeſome Nouriſhment for them: but Sheep ſhould have them while young, elſe they do not ſo well take to them.

Handhoeing of Turnips, which is all that can be done according to the common Practice, is but a very poor Method at beſt, and it is generally ſo ſlighted over, that the Farmer is extreamly cheated. The Hoers, inſtead of breaking all the Ground, tear up the Surface of one half, and draw it over the other, covering the Weeds with it, inſtead of hoeing them up: ſo that, inſtead of being deſtroyed, they are only made to grow the ſtronger.

Drilling upon the Level was the firſt Practice with Turnips, but it is a very bad Way. When they are drilled on Ridges the Hoe Plow may come near the Ridges, and go deep without Miſchief, but in the other Way the young Turnips are often buried by the Earth falling over on the left Side of the Plow. Turnips planted on Ridges, at ſix Foot Intervals, have been found to yield double the Quantity with thoſe planted on the Level, with three Foot Intervals: and when every other Article is the ſame, the Produce is found, by repeated Tryals, to be much greater from the ſix Foot Interval, than the three Foot.

The beſt Method of ſowing by the Drill, is to let half the Seed fall into the Bottom of the Trench, which is to be four Inches deep; and the other half over it, at about half an Inch Depth, lying upon the Earth that has fallen in upon the other: and if half new and half old Seed be mix'd, as before hinted, and the drilling performed in this Manner, there will be no leſs than four different Shootings one after another; ſo that there will be four Chances inſtead of one, of their eſcaping the Miſchief of Inſects. It is

lucky for the Farmer, that as Turnips are liable to this Accident, the Seed is ſo ſuited to the Purpoſe of preventing it. For Turnip Seed will bear to be buried very deep, and come up well; and by this Method of mixing the Seed, and ſowing at two Depths, there will be new Quantities riſing for a Fortnight together.

If all theſe Chances do not prove ſufficient, the young Turnips may be hoe plowed when they are in the greateſt Danger, which will bury a great Part of the Inſects; or at the worſt another Row may be drilled in, without doing any thing more to the Land.

When the Land has been well prepared, and made very fine, the Roller may be uſed with a great deal of Succeſs, upon a Turnip Field ſown by the Drill. We have mentioned already, in our Account of that Inſtrument, the great Advantage the Farmer has from it in the deſtroying Inſects; and there is no Kind that it more perfectly kills than theſe little Flies and their Brood, which prey upon the Turnips.

The Farmer often has Recourſe to his Roller in the common Way of Huſbandry, when he ſees there is Danger from the Fly; but in deſtroying the Inſect he ſpoils his Crop: for it makes the Ground ſo hard, that the Turnips, which require a looſe light Soil, cannot thrive in it. But in the Drill Way there is no Danger. The Ground may be rolled for the Deſtruction of the Inſects, and the Hoe Plow will ſufficiently break it up, and looſen it again. The right Method is to roll the Land acroſs the Ridges, after it is drilled. The Turnips may be after this thinn'd at a ſmall Expence, by Hand Hoes; and the Hoe Plow will then work wet or dry, and if they have been ſtopped a little in their Growth by the rolling, they will preſently revive and recover after this Practice.

CHAP. LXIII.

Of the Quantity of Seed, and Advantage of the Crop.

IN general three Ounces of Seed, or between three and four, is the right Quantity for an Acre of Ground, ſometimes two Ounces will do: and in the uſual Way, although we have mentioned two Pound, many uſe three or four.

The Farmer may leave the Ridges, when the Turnips are drill'd in ſingle Rows, with ſix Foot Intervals, higher than he can for double rowed Crops; becauſe there will be more Earth in the Intervals.

When the Turnips are planted in ſix Foot Rows, Wheat may be drilled between them; and in the ſame Manner Turnips may be drilled in between Rows of Barley, and Rows of Oats very ſucceſsfully. In theſe Caſes, the poorer the Land is, the wider ſhould be the Interval.

When Wheat is ſown between Rows of Turnips the Method is this. At MICHAELMAS, when the Turnips are full grown, a Ridge is to be plowed up in the Middle of every Interval, and the Wheat drilled on it: and then the Turnips are to be pulled up toward Spring, and carried to the Cattle.

In the thinning of the Turnips Regard muſt be had to their Appearance, and thoſe well growing ones which the Farmers call Maſter Turnips, muſt be left two together, if they happen to ſtand ſo, leaving the greater Space on each Side of them. But if three grow together the middle one ſhould be pulled up.

When Turnips have been ſown late, the alternate Hoeing deſcribed before, will ſometimes do; but for ſuch as have been ſown early it will be neceſſary to hoe them again. The beſt Inſtrument for breaking the Earth left about the Edges of the Rows by the Hoe Plow, is what they call, in ſome Places, the Prong Hoe; this has commonly two, ſometimes three Teeth, and that with three is beſt: but this Inſtrument muſt not be uſed till the Turnips are of ſome Growth.

When the Intervals are hoed alternately, the Plow may go deeper and nearer the Row, becauſe it is ſupported on the other Side, but this is only to be done when the Plants are ſmall: at that Time it is very beneficial, but afterwards it would be dangerous. At the laſt Hoeing it is a good Method to leave a broad deep Trench in the Middle of each Interval.

The Crop of Turnips has a vaſt Advantage when raiſed this Way, over thoſe by the common Method of ſowing, in that they are better able to bear a dry Seaſon. The Hand Hoe does not go deep enough to do any Service againſt this Accident, which ſpoils many a promiſing Crop: but the Horſehoe breaks the Soil to ſuch a Depth, as ſaid before, that it always keeps moiſt.

We have adviſed the Farmer before, to the Uſe of Manures for his Land intended for Turnips; and even Dung is allowed to be uſed for this Crop, by Mr. TULL its great Enemy, becauſe he acknowledges that Dung and Tillage together, will divide and break the Land in leſs Time than Tillage alone; and this is a very neceſſary Article in the Conſideration of Turnips, becauſe they have ſo ſhort a Time to grow.

The ſame Miſtake may naturally happen in judging of Turnips ſown in ſingle Ridges, with theſe large Spaces, as we ſee People run into about Corn drill'd the ſame Way; that is, they may ſuppoſe fewer ſtand upon an equal Space of Ground; but here it is eaſy to confute the Suſpicion by counting. The beſt Judges of Turnips leave only thirty to a ſquare Perch when they have been ſown in the common Way, but when they are drilled with Intervals of ſix Foot, there may be five and forty left upon every Perch of Ground, and each will be much larger than thoſe of which there are but thirty in the common Way. This has been proved by Trials, and is a Fact againſt which there can be no arguing, ſixty may be left in a Perch, and they will thrive very well; and allowing theſe only at five Pounds apiece, they will make a Crop of above eighty Quarters to an Acre.

When Turnips are drilled late, and it is upon a poor Ground, they will not be able to grow very large, and therefore the greater Number is to be left. For the ſame Advantages that would, in more Time, make a ſmaller Number grow big,

big, will ſupport a greater Quantity of ſmall ones, and their Number will make Amends for the Want of Size in every Particular.

CHAP. LXIV.

Of raiſing Wheat by the Drill and Horſehoeing Huſbandry.

AS Turnips are beſt raiſed in ſingle Rows, becauſe of the Largeneſs of their Roots, Wheat is found to ſucceed beſt in treble Rows, with ſufficient Intervals between one Set of Rows and another. We have ſeen the Advantage this Method of Tillage has, in Reſpect of Turnips, over the common Practice, but its Benefit with Regard to Wheat is greater.

The longer any Plant is to remain in the Earth, the more Nouriſhment it will require, and Wheat is three Times as long in the Ground as Spring Corn; being ſown in the preceding Autumn.

The Farmer knows that it will want a great deal of Nouriſhment in this long Growth; and therefore he dungs his Land to give it; and never ſows Wheat but on Land thus prepared, and well tilled beſide. He thus gives it a great Fund of Nouriſhment, but it is all laid in at once; now it would certainly be better to afford it this Supply at Times, as it continued growing. This repeated Aſſiſtance cannot be given it in the common Method, but it may in the Horſehoeing Huſbandry; and it is therefore plain this Practice is particularly well ſuited to that Kind of Corn. Reaſon confirms this, and it is ſupported by Experience, for Crops of Wheat upon the ſame Ground are much larger when raiſed by this Method, than by any other.

The Earth is prepared for Wheat in Autumn, but it is in Spring it wants moſt Nouriſhment, for then it begins to ſhoot; but by that Time the Ground has got almoſt into its original Condition again.

When the Farmer is preparing his Land for Wheat in the Horſehoeing Method, let him take Care of all Things to free it from Graſs. Other Weeds may be deſtroyed by the Methods uſed in that Practice, but this very difficultly. Other Weeds may be got out when among the Rows; but Graſs cannot, and it is ſo pernicious that one Bunch of it will ſpoil a Yard of the Crop.

The Ridges for the drilling of Wheat ſhould be made ſtrait and equal; the Plowman who underſtands his Buſineſs knows how, by ſetting up a Mark, to carry on the Line quite ſtrait: and to make theſe Ridges even he needs only mark out ſeveral of them, before he begins. But if the Piece be of ſuch a crooked Form that the Ridges cannot be plowed ſtrait the firſt Time, it may be proper to drill it upon a Level, and all the Ridges for the next Crop may eaſily be made equal.

Six Foot Ridges, being in Number eleven on the Breadth of an Acre, they ſhould be made lengthways of the Field, unleſs there be ſome Reaſon to the contrary: as if it be a Hill any thing ſteep. In this Caſe they muſt go up and down, whether that carry them lengthwiſe or breadthwiſe of the Piece: for if the Ridges ſhould go acroſs ſuch a Hill, they could not be well Horſehoed.

As to the Height of the Ridges, the various Nature of the Ground makes a great Difference, but as Wheat always ſucceeds beſt when it is dry, a Foot may be given for a general Height as a Medium. When they are narrow with this Height, and have a deep Furrow on each Side, the Water that Rains throw upon them ſufficiently moiſtens the Ground for their Service, and runs off without poaching them.

The deeper the Soil is the higher the Ridges may be conveniently made, and the wetter the Land is the higher they ought to be. In ſhallow Soils the Ridges cannot be made ſo high, becauſe there would be a Deficiency of Mould in the Intervals. But however high the Ridges are made, the Tops of them muſt not be ſo narrow and ſharp for drilling of Wheat, as they are for Turnips, becauſe the Wheat is to ſtand in a treble Row, whereas the Turnips do beſt in ſingle Rows. And a ſingle Row taking up leſs of the Breadth, may have more of the Ridges Depth, becauſe it leaves the Interval wider.

As there is this Difference in the ſowing of Wheat by the Drill Way, ſo there is to be a great deal in the reaping, for the Stalks are to be cut off cloſe to the Ground. This could not be done in the common Method, but it may very well in this, becauſe all the Plants riſe regularly in the Rows together.

When this is done, and the Crop is carried off, if the Trench in the Middle of each wide Interval have been left as deep as it ought by the laſt hoeing, as ſoon as may be, the Farmer ſhould take a common Plow to the Ground, and go as near the Stubble as he can; and turn two large Furrows into the Middle of the Intervals. This will make a Ridge over the Place where the Trench was.

If the Trench have not been left ſo deep as it ſhould be, then he is to go firſt in the Middle of it with one Furrow; which, with two more taken from the Ridges, will be three Furrows in each Interval. This plowing is to be continued as long as the dry Weather laſts, and then the Plowman is to finiſh, by turning the Partitions on which the laſt Wheat grew, up to the new Ridges. This is uſually done at two great Furrows: and theſe laſt Furrows, which compleat the Ridges, may be plowed in wet Weather.

Sometimes more Furrows will be required to make a ſix Foot Ridge very high. Thus when the Middle of the Intervals are very wide and deep, there will require ſix Furrows to the whole Ridge, and they muſt not be ſmall ones. The Seaſon alſo, in this Caſe, makes a Difference, for when the fine Mould is very dry, a great deal of it will run to the left Hand before the Plow, and more will run back again to the left, after the Plow is gone paſt.

When ſuch Ridges have been made for Wheat, and the Seaſon continues too long dry for planting it, and the Stubble not thrown up, let the Farmer then plow one deep Furrow on the Middle of each Ridge, and then plow the whole Ridge at four Furrows more. This will raiſe it very high. This Practice ſtirs all

the Earth of the Ridges, and is done at five Furrows.

This is a very important Article of the Farmer's Concern in the Drill Husbandry, but he may be guided in it with great Safety by a few general Rules. The Furrows necessary for raising of Ridges must be more or fewer in Regard to the Bigness of them. The Plowman, as well as his own Reason, will inform him that six small Furrows may be less than four large ones.

'Tis best not to plow the Stubble up to the Ridges till just before planting; especially in the early plowing, because that will hinder the replowing of the first Furrows, which, if the Season continues dry, may be necessary. This may be done by opening one Furrow in the Middle, or by opening two, and afterwards the Ridges are to be rais'd up again. When they are become moist enough at Top, the old Partitions being plowed up to them, they are to be harrowed once lengthwise, and then drilled.

The old Partitions must be plowed up to the new Ridges, to support their other Earth from falling down with the harrowing and drilling, which would else make them level.

The Ridges in this Way of managing Lands, greatly excel common Ridges of the same Height, because, being made upon the open Trenches, they consist of new tilled Mould from Top to Bottom; whereas the others, though as deep in the Mould at the Tops, have little of it tilled at the last plowing.

All other Sorts of Grain succeed best when they are sown at a Time when the Ground is so dry, that it can be broke into most Parts by the Plow, but Wheat is an Exception. The Reason is, that Wheat is to stand the Severity of a Winter, and in order to this the Ground must fall closer upon it, and it does so when somewhat wet at the Time of the sowing.

As a general Rule we may tell the Farmer, that in this Method of Husbandry especially, it is best to plow the Ground when it is dry; and then let it lie till it become moist. If this does not happen under several Weeks, he should stay for such an Opportunity. But in speaking of this Dryness and Moisture of the Ground, we are to be understood as meaning in Moderation: the Land need not be so dry as to fly like Dust for the plowing; nor should it be as wet as Pap for drilling; but in a moderate Way on each Side.

Wheat is a very particular Kind of Grain. It is too tender to be sown in a dry Time, as Rye may be. It requires the Earth to lie firmly about it in Winter, to support its Roots; and it requires it should be tender in Spring for their Passage. This is seen by Experience; and there is no Way to give it these Advantages, like sowing it by the Drill, in Earth that has been well broken by the Plow, and is become a little moist; and afterwards breaking the Earth all about the Rows in Spring by Horsehoeing.

After Rain, when the Ground is of a right Degree of Moisture for drilling of Wheat, let it be harrowed with two light Harrows drawn by a Horse, going in a Furrow betwixt two Ridges. This will be sufficient in most Cases, the Furrow being just broken to level or smooth it for the Drill.

If the Ground whereon the next Crop is to stand be plowed dry, the Farmer may drill at any Time during the Season for sowing the Kind of Wheat he uses in the common Method, but it is better to drill a little earlier than the Farmers sow in the common Way, than later. The Season for sowing by the Drill, in general Terms, may be said to last from Harvest to the Beginning of NOVEMBER.

When Wheat is drilled early less Seed is required than when late, for less of it will die in the Winter. The Farmer is also to consider the Nature of his Land, in proportioning the Quantity of Seed. More of the Plants will die in Winter on poor than on rich Ground, and he must therefore allow more Seed to poor Land, than he does to rich, to provide against this expected Accident.

When the Farmer has a rich Piece of Land, and drills it early, he is to use less Seed than on any other Occasion, because every Grain, in a Manner, will come up, and very few of the Plants will die: and in this Way of Husbandry, a few Plants thriving well will send out a Multitude of Stalks, and bear an Abundance of Ears: so that the Number of Seeds sown is not the great Consideration. Let the Farmer also regard, as we have before observed, the Size of the Seed Wheat: for its Number, not the Bulk, is to determine his Quantity. The smallest Grain of Seed Wheat will produce as large a Stalk, Ear, and Corn as the biggest.

On rich Land sown early by the Drill, four Gallons of middle sized Seed Wheat is sufficient for an Acre. But in general, six Gallons in the common Run of Land, is the best Quantity. A great deal depends upon this suiting the Quantity of Seed to the Land and the Season, for if the Corn be drilled too thick, it will be in danger of falling, and if too thin it will be subject more than otherwise to Blights. We mention the Danger either Way, that the Farmer may be upon his Guard, and we have given him all the necessary Rules for conducting this important Matter; a little too much, or a small Matter too little of the Seed is not so very mischievous, but we have shewn him what happens when it is much wrong either Way; and he is to take Care accordingly.

As to the Depth of drilling the Wheat; it may be done from half an Inch to three Inches; but when it is planted too deep it is in Danger of being eaten off by the Worms in Winter; this it escapes if shallow, because they do not lie near the Surface in the severe Weather.

Just when the Wheat begins to peep above the Ground, let the Farmer beware of the Rooks. They will perceive it shooting before he sees it, and that is the Time they attack it. Let him keep them off the Field for about ten Days at this Period, and all will be safe, the Corn will then be exhausted of its Flour, and they will not seek it.

The later Wheat is drilled the more it is in danger of the Rooks, for if it be done soon after Harvest, while there lies a good deal of loose

Corn about the Ground, they will not trouble themſelves about that which is buried.

CHAP. LXV.

Of the Number of Rows for Wheat.

WE have ſhewn the Method of plowing and preparing the Ground for the drill and horſehoeing Huſbandry, and the Quantities of Seed Corn neceſſary under the different Circumſtances for ſowing it. We now come to a very material, and very important Conſideration; which is, the Number of Rows that are to be allowed to the Intervals.

We have obſerved already, that the drill may be made to ſow in ſingle, double, treble, or other more numerous Rows, according to the Farmer's Pleaſure. We have ſhewn that in Turneps the ſingle Row is preferable; but in reſpect to Wheat, that Point is not ſo well determined.

Experiments have been made of various Manners; and it is from the Reſult of them we are to determine. Some have ſown Wheat in a ſingle Row, and left the full Interval for Horſehoeing between; others have drilled it in Multitudes of Rows, with few or no Intervals of any Space between them; but theſe are the Extremes, and are equally wrong. In the Make of the Drill Plow for Wheat we have contrived for the Sowing it in three Rows, which is a very good Method; but ſome prefer to this the Method of only two Rows; and they have in many Circumſtances a great deal to advance in their Favour.

Of this the Farmer may be ſure, that one of theſe two laſt Methods he is to prefer; whether it ſhall be that by the double, or by the treble Row, he muſt determine from the Nature of his Ground. If he drill in treble Rows, the Partitions muſt be ſeven Inches; if in double, they ſhould be ten.

Where there is only a double Row, the Weeds are eaſier deſtroyed between; but then in the treble Rows there ariſe fewer of them. It muſt be allowed, that in the treble Rows Weeds are not ſo eaſily rooted up, without damaging the Corn; in the double Row there is leſs Hazard: therefore the Farmer will ſee, that if his Ground be very liable to Weeds, all other Conſiderations being equal, it will be beſt to ſow it in double Rows; if it be naturally pretty free from them, it will be beſt in treble Rows. This is what we mean by adviſing him to conduct himſelf according to the particular Circumſtances of his own Farm; and this in all Articles is very material.

In Favour of the double Row way, it is farther to be obſerved, that the Hand Hoe cannot work nearly ſo efficaciouſly in two ſeven Inch Partitions as in one of ten Inches: and the Quantity of Earth to be wrought by the Horſe Hoe is more when there is only a double, than when there is a treble Row.

A leſs Depth of Mould on the Ridge will do for the double than for the treble Row; and this will ſerve as a Direction in reſpect of the Farmer's particular Circumſtances.

Six Foot Ridges are abſolutely neceſſary to the treble Rows, but not to the double, becauſe the Partition between the two Rows can be very well clear'd, and well wrought, by the Hand Hoe; and the Earth of the Interval is wrought with much more Eaſe and Convenience: and let the Farmer obſerve farther, that in deep and rich Land theſe Intervals between double Rows may be much narrower than they can be made with Prudence in poor Lands, eſpecially when planted in the treble Rows. The wideſt Intervals of all are required for treble Rows of Wheat in poor Land; in other Reſpects the Farmer is to conſider the richer and deeper the Soil, the leſs will do between the Rows; and let him take in the Aſſiſtance of Manure, to make it more rich, and then it will do in ſtill leſs Quantity. He will find it beſt not to oppoſe the new Method againſt the old, but to join them for his Convenience.

The Management of the Hoe Plow is a very great Article; and the Farmer muſt take Care he employs an expert Plowman. The Intervals ſhould never be too wide to be horſehoed at two Furrows, without leaving any Part unplowed in the middle of them; and the Farmer will find, that by making the Plank of this Plow ſhort, and the Shafts crooked, ſo far as each will bear, he will be able to hoe with it in narrower Intervals than he may at firſt imagine, without damaging the Wheat.

When the double Row is uſed, there may be fourteen Ridges in an Acre; there will then be only one Partition on each that is between the two Rows; and its Breadth is ten Inches.

This Method brings the new Huſbandry nearer to the old: And as we ſhall adviſe the Farmer, in all reſpects, to come as near as he can toward uniting them, we ſhall adviſe him to harrow the Land, after Drilling, with the common Harrow; it will cover any of the Seeds that may chance to have been left bare by the drill Harrow, and encreaſe the Growth.

The hand hoeing between theſe double Rows is very eaſy; but let the Farmer ſee that it is done properly, and not ſlighted over: In the doing of this, the Earth muſt never be turned toward the Wheat; for it may cruſh the Wheat while it is ſo young and tender, as at this Operation, and the Partition would never be hoed clean.

The Hoes for this uſe ſhould have the Edge ſeven Inches long, and be four Inches deep from the Handle; they muſt be thin, and well ſteel'd; and this Work, at a moderate Price of Labour, may be done at about eighteen Pence an Acre, the working People finding their own Tools.

For the Wheat that is drilled in three Rows, four Inch Hoes are more convenient.

In low Ridges, when there are three Rows, the middle one is poor; in high Ridges it is as good as the others; but the Queſtion remains, whether it is not rich at their Expence: perhaps as much is loſt in them as is gained in that. Mr. Tull himſelf became of this Opinion, and changed at laſt his Method from the treble Row to the double. Whether or not he was in the Right we would have the Farmer find not by reaſoning and arguing, but by Trials on different kinds of Land.

Peaſe may be drilled by the ſame Drill as the Wheat, when it is made for the double Row, only

only the Spindle ſhould be changed for one that has the Notches a little bigger. This two Row Method for Peaſe is preferable to any other, becauſe the Earth may be thrown ſo far upon the Peaſe in the ſecond Horſehowing, that the two Rows become one, which is very convenient. If Barley be drilled, the three Row Method is preferable to the two; but this is not proper to be followed by a Crop of Wheat, without a Fallow. There is the ſame Objection againſt Oats alſo, becauſe ſome of their ſcattered Seeds will live out the Winter Riſe among the Wheat, and hurt the Sale.

CHAP. LXVI.

Of the Manner of Horſehoeing of Wheat.

WE have left the Point between the double and treble Rows undetermined, becauſe each Way ſucceeds very well, and ſome being of one Opinion ſome of the other, among thoſe who have tried: there ſhould be more Experience to determine which is in general the beſt; but which ever Way be preferred in that Reſpect, the Practice of Horſehoeing is the ſame, altho' that of Handhoeing differs.

The firſt Horſehoeing is to be performed by turning a Furrow from the Row; and when the Weather is wetter when this is performed, the Plow may go nearer the Row, without Miſchief; and when dryer, it muſt be carried ſomewhat more diſtant.

As to the time of doing this, it is beſt when the Wheat has got three or four Blades: but it ſhould never be done till it have more than one Blade. If the Crop have been drilled early, it muſt be done before, or in the Beginning of Winter, according to the Condition of the Blade; but when it has been drilled very late, it need not have the firſt hoeing till Spring. In this firſt hoeing let the Farmer have a ſtrict Eye upon thoſe he employs, for a great deal depends upon it. Let him ſee that they go as near the Rows as they can do, without damaging the Corn; and as deep as they can, without going below the good Soil.

If upon looking over the Ground afterwards, he finds that the firſt Furrow was not near enough the Rows, nor deep enough, let him order a ſecond Furrow to be plowed at the Bottom of the former; and if this cannot be conveniently done ſoon after the firſt hoeing, let it be done before the Ridge is turned back in the Spring. And let the Farmer remember always to have the Furrows turned up, to make Ridges in the middle of Intervals, during Winter.

Let him not be afraid of expoſing his Rows of Corn to the Froſts, by hoeing off the Earth from them in the Beginning of Winter; for it is found by Experience, and there is no arguing againſt that, that when the Hoe has gone neareſt, the Plants thrive beſt.

The Row in this caſe ſtands, as it were, upon the Brink of a perpendicular Ditch, and the Water therefore runs off from it; and we know dry Earth is not affected by Froſt like ſuch as is wet. The Plants are thus preſerved during Winter; and in Spring the Ridge from the middle of the Interval is thrown upon them, which is full of new Nouriſhment, having lain all this Time in the manner of a Fallow, altogether unexhauſted.

As ſoon as the Froſts are paſt, and the Weather will allow it, let the Intervals have their ſecond turning: this is called the Spring hoeing. The Ridge from the Middle of the Interval is then to be thrown, as before obſerved, to the Rows on each Side, by two Furrows, as near as can be done without covering the Wheat.

After this Spring hoeing, the Farmer is to be guided in what he does by the Circumſtances and Nature of the Land, and by the Weather. The great Cautions he is to have, are never to let Weeds grow to any Height in the Intervals; and never to let any unmoved Earth lie in the Middle of the Intervals long enough to grow hard.

By theſe two Meaſures, he will be guided in his Work during the Summer; and theſe are to direct how many Hoeings the Intervals are to have, better than any general Rule; only let him obſerve, that he muſt never plow deep near the Rows in Summer, when the Plants are grown large; but, at the ſame time, let him take Care to plow as deep in the Middle of the Intervals as the Soil will allow; and let him turn the Earth towards the Wheat, eſpecially at the laſt hoeing, ſo as to leave a deep and wide Trench in the Middle of each Interval.

This is the Method of raiſing Wheat by the Drill and Horſehoeing Huſbandry. Whether the Method by two or by three Rows be the beſt, muſt be determined by more Tryals on Lands of different Kinds and Natures; but whichever of theſe be taken, the Advantage of the Horſehoeing ſhews itſelf in an aſtoniſhing manner. The Crop is vaſtly greater than any other Way; and it is increaſed by augmenting the Number of Stalks of Ears and of Grains.

The Stalks, inſtead of two or three, are thirty or forty from each Grain; and whereas a great Part of the Stalks in the common Huſbandry do not come to ear; and of thoſe that do, a great many have Ears very ill fill'd, in this Method, with the Advantage of Horſehoeing, all the Stalks come to ear, and every Ear is full of good Grain.

There is no way of producing a large and full Grain in the Ear like late Horſehoeing. If this be done juſt when the Wheat is gone out of Bloſſom, the whole Stock of Nouriſhment that it conveys is carried up directly to the Grain, and the Crop will be doubled by this Method.

It is by theſe Means that the Horſehoeing Huſbandry produces a greater Crop than the common, from a tenth Part of the Plants; for it increaſes the Number of Stalks; it carries them all up into Ear; it makes the Ear large; and the Grain plump, and full of Flower. This it will always be found upon Examination to effect; and the Conſequence is here very plain. Fourſcore Ears have been counted upon one Plant; and there have been numbered a hundred Grains in one Ear. If the Wheat Plant be capable of this vaſt Increaſe and Product, there is an ample Field for the Improvements that may be made by any Method of Huſbandry, which ſhall better than the others promote its Growth.

CHAP.

CHAP. LXVII.

Of the immediate Benefit of the broad Intervals.

WE have obſerved that the Generality of Farmers are averſe to the broad Intervals neceſſary to be left for the Horſehoeing, and the Prejudice is very natural: it ſeems leaving ſo much of their Land unoccupied. We have before ſhewn that this is a Miſtake; but it is here that we may moſt abundantly prove it, arguing from Experience.

We ſee a Plant of Wheat is capable of a vaſt Encreaſe; and if we aſk how it is to be promoted in that Augmentation, the Anſwer is very plain, for it can only be by giving it more Nouriſhment. There are two Ways of doing this, the one by making the Earth richer, and the other by allowing more Compaſs of it for the Roots to run in. The firſt Method is done by adding Dung and other Manures; the other by leaving theſe broad Intervals, and tilling them with the Hoe Plow. The latter Method will ſucceed much better without the former, than the former can without that; but they will have their fulleſt and fineſt Effect when they are uſed together.

To ſhew the Advantage however, in its faireſt Light, we will at preſent conſider the Horſehoeing Method, with the Advantage of its wide Intervals alone, and without the Aſſiſtance of any Addition.

We ſee then that we can, by allowing wide Intervals between double or treble Rows of Wheat, produce a good Crop with leſs Labour and leſs Seed than are needful in the common Way, and without the Expence of Dung, or the Loſs of Time in fallowing. Theſe are plain Advantages: there is no Difficulty in the Practice: and we hope therefore the Farmers in every Part of the Kingdom, where there is a proper Soil, will give it a fair Trial.

If it be ſuppoſed that the Roots of Wheat do not extend ſo far as half Way of theſe broad Intervals, we have ſhewn already that it is aſſerted upon Conjecture, and is moſt likely to be an Error; and even if it were true it would amount to no Objection of Weight: for this Breadth is abſolutely neceſſary for the working of the proper Inſtruments; and at the laſt hoeing the Earth is thrown on each Side toward the Rows, and a vacant Space left in the Middle of the Interval, ſo that they certainly then have the Benefit of it all, and that is the Time when they moſt of all want it. There is, at this Time of the Growth, no Part of the Earth of the Interval diſtant above ſeventeen Inches in the double Rows from the Plants, or above two Foot from the middle Rows, when there are three. Thus far the Roots of Corn may be proved to reach, and the Earth is given them new tilled, and full of Nouriſhment for the feeding of the Ear.

We have ſaid that in deep Land the Intervals may be narrower than in ſhallower; but ſtill they muſt be wide enough for the Inſtruments to work in it; and if in ſhallow Land they ſhould be narrow, there would not only want Room to work, but Earth to work upon.

The Practice of Horſehoeing will ſupply the Place of Fallowing and of Dung; but there muſt be Earth for it to work upon: therefore there muſt be a ſufficient Breadth of Interval, and a ſufficient Depth: if the Intervals be ſo narrow that nearly all the Earth of them goes to make the Tops of the Ridges, there will not be enough to ſupport the Plants, let it be ever ſo much improved by Tillage. There muſt be a Quantity of Land as well as Quality, for the ſupporting of a Crop; and as Land is cheaper than the Expence of Manure, why ſhould not the Farmer who regards his own Intereſt allow it.

Weeds are very apt to grow in the Intervals that are hoed, but then they are ſoon deſtroyed. They grow readily becauſe the Earth is greatly improved by Tillage; but as they are deſtroyed before they come to Seed, by the repeated plowing of the Intervals, the Damage is nothing. The Ground is not ſtocked with freſh Supplies of them, and they even add the Benefit of a Manure by rotting in the Ground.

It is plain that the Drill and Horſehoeing Huſbandry produce larger Crops in the ſame Piece of Ground, than the common, and at leſs Expence; and it is equally certain that this Advantage ariſes from the thorough breaking and dividing of the Ground in the Intervals with the Hoe Plow. The Neceſſity of allowing theſe Intervals a due Breadth is plain, becauſe the Work cannot be perform'd in them if too narrow; and becauſe they cannot ſupply the Rows ſufficiently, if there be not Subſtance or Quantity of Earth to work upon. The Advantage is certain, and the Neceſſity of Breadth in the Intervals is ſo plain, that at the ſame Time that we expreſs our Wiſhes that every Farmer would give the Practice a Trial, we hope none will attempt it without giving this due Compaſs to the Intervals, becauſe that would not be giving it a fair Trial; and the Importance is enough to beſpeak at leaſt Candour in the Experiment.

CHAP. LXVIII.

Of raiſing Saintfoin by the Drill and Horſehoeing Huſbandry.

WE ſhall, in a ſucceeding Chapter, conſider the Nature and Qualities of Saintfoin: we are here giving the Culture of it by the Drill and Horſehoeing Huſbandry, as an Inſtance of the Benefit of that Practice, and of the Extent to which it is capable of being carried in the Farmer's Profeſſion.

The great Advantage of Saintfoin is owing to the Length of its Root. This pierces to a vaſt Depth in the Earth, and will therefore ſupport a large Growth of it, where the natural Graſs would be little. This is its particular Benefit, and there is no Way of raiſing it equal to that by the Drill and Horſehoeing Huſbandry.

The drieſt and pooreſt Ground may, by a proper Management, be made to produce good Saintfoin, but the fineſt and beſt will always be had from the beſt Soil.

When the Farmer is about to raiſe Saintfoin, let him ſee to prepare his Land well for it; and then let him take Care to lay in the Seed carefully, otherwiſe very little of it will grow.

The Depth at which Saintfoin Seed is drilled, is a very material Conſideration. In moderate Land it ſhould be covered half an Inch deep, and in ſuch as is very dry and light a little deeper, but nothing is ſo dangerous as the burying it too low in the Ground. No Seed whatſoever is ſo unable to bear it: but though it requires to be covered ſo very little, yet it abſolutely requires to be covered: for if it ſhould be left naked upon the Ground, it would not ſhoot at all, or will periſh when it had juſt ſhot; we give the Farmer his full Cautions, and on his Regard to them will depend his Succeſs.

The Quantity of Saintfoin Seed to be ſowed by the Drill, is about a Buſhel to an Acre. This allows twenty Seeds, or thereabout, to each ſquare Foot of the Ground.

Let the Farmer be very careful in the buying of his Seed. It is often bad, and then, with all his Care, his Ground will be underſtocked with Plants.

The beſt Seaſon for drilling of Saintfoin is early in the Spring. It is a common Practice to ſow it in the Beginning of Winter, but that is very bad; and to ſow it in the Heat and Drought of Summer is worſe.

Laſtly, in order to have a good Growth of Saintfoin, let the Farmer ſow it alone. It is a common Practice to ſow it with Barley or Oats, and this is very wrong: ſome ſow it with Clover or Rye-Graſs, and that is worſe, it never ſucceeds perfectly, unleſs when it is let into the Ground without Mixture.

The Farmer who is uſed to ſowing of Saintfoin, in the common Way, will be ſurpriſed at what is here ſaid, with Reſpect to the Quantity of the Seed. Six or ſeven Buſhels to an Acre is the uſual Allowance in the ordinary Way; but in the ſingle Buſhel we allow in this Method, we compute for a great deal of bad among it, for a much ſmaller Quantity of Plants than would be thus rais'd from good Seed will be ſufficient. In general there is no Crop that ſo well bears to riſe thin as Saintfoin, for it grows larger and ſends out more Branches in Proportion as it ſtands more ſingle.

When Saintfoin ſtands the moſt ſingle, in Moderation, it will yield the largeſt Crops. It ſpreads its Roots to a great Depth and Diſtance, and a few well nouriſhed Plants are more than a great many that are but half fed. The common Length of the Saintfoin Stalks is two Foot or a little more; but when it ſtands far aſunder they will grow to ſix Foot.

The Root of this Plant is found to encreaſe in Length and Thickneſs, in Proportion as it is farther from other Plants; and as the Root encreaſes the Stalks always keep encreaſing. The greater the Number of Plants of this Kind there are upon a Piece of Ground, the ſmaller they are; and their Number never makes Amends for this Deficiency in their Growth. When there are but a few Plants upon the Ground, they will ſupport themſelves without Aſſiſtance, and encreaſe every Year in Strength and Produce; while on the other Hand, the great Number that are ſometimes raiſed by unſkilful People, while they produce leſs, require Manure or they will periſh.

From the Nicety required in laying in the Seed of Saintfoin, it is eaſy to ſee that the Drill Huſbandry is much better ſuited to its Produce than the common; but here is another Reaſon: we ſee that if the Plants ſtand too thick they are ſtarved, and yield little; but in this new Method they are in leſs Danger of this Miſchief, becauſe they are ſure of having Room on both Sides, though they ſtand thick in the Rows; if the Intervals be allowed a due Breadth: and there is no Crop which requires to have them larger.

When this Plant is kept at a due Diſtance, the ſecond Crop riſes immediately after cutting: but when they ſtand thick it does not ſhoot till there comes Rain. A moderate Diſtance is the planting about a hundred Plants on a ſquare Perch, and theſe will very well yield two Ton to an Acre.

If the Farmer follow our Direction of drilling his Saintfoin Seed early in Spring, and take Care to hoe it well afterwards, he will, if the Seaſon be favourable, have a Crop the firſt Summer: this he is not to expect in the common Method of Management, but this Way it will be a very pretty Addition to his Profit: and the Roots having Time to ſtrengthen themſelves in the Earth, by this early taking off the Head, will thrive the better for the ſucceeding Years.

On many Lands, in the common Way of Management, Saintfoin yields but one mowing Crop in a Year; but with right Management it will yield two very large ones.

There is no Plant that has more Advantage from hoeing than this. A Quantity of hoed Saintfoin will grow more in a Fortnight, than ſuch as is unhoed in the ſame Land will in ſix Weeks; and that which is hoed will be freſh, green, and ſtrong, while the other is poor and yellow.

From theſe general Obſervations we may lay down Rules for the Management of this beneficial Plant, which will be as certain of Succeſs as the Experience on which they are founded is true.

CHAP. LXIX.

Of the Manner of planting Saintfoin.

THE beſt Method for raiſing Saintfoin by the Drill and Horſehoeing Huſbandry, is to drill it in double Rows, with eight Inch Partitions, and with Intervals of two Foot and an half: and theſe Intervals are afterward to be hoed only alternately, leaving the other to make the Hay upon. The Benefit of Horſehoeing is very evident upon this Plant, for it makes it thrive exceſſively on very poor Land; and will cauſe it to yield two very good Crops, where it would otherwiſe have afforded but one, and that indifferent.

Leſs Horſehoeing is required for Saintfoin, than for any other Plant. In very good Land it may be omitted for two or three Years, but

when the Ground is poorer it muſt be repeated oftener; and whenever the Crop is ſeen to fade, this will refreſh it. While the Plants are ſmall Care muſt be taken not to cover them with the Plow, but afterwards there is no Danger.

We have ſaid that the Land muſt be well prepared for this Plant: and we are to add, that great Care is to be taken in the whole Operation of raiſing it. The Ground muſt be made perfectly clear of all other Growths, and well broke by Tillage; and Care muſt be taken that the Tines of the Drill Harrow exactly follow the Shares, for the covering of the Seed.

No other Harrow is to come upon the Ground after the Saintfoin is ſowed: nor is it to be rolled. Thoſe who ſow it with Barley muſt roll the Ground for the Sake of that Corn: but we adviſe the Farmer to ſow it alone, and then he is not to roll the Ground after it.

Let him take Care that no Cattle come near the Saintfoin when it is young, and in the firſt Winter let him give it a little Manure of Soot or Aſhes; this will greatly encourage its Growth, and the next Crop will very well pay the Expence.

This he will certainly find to be the Difference between drilling Saintfoin, and ſowing it in the common Way, that the Expence of drilling is hardly a twentieth Part of that in ſowing it the other Way, and that the Profit of the Crop is generally double.

We have obſerved that leſs Horſehoeing is neceſſary to Saintfoin than to any other Crop, when that Method of Huſbandry is practiſed; and it will be proper to add here, that this Plant will ſucceed extreamly well by the Drilling, without the Addition of the Horſehoeing Article. It may be ſown for handhoeing, or for ſtanding without any Kind of hoeing at all; but in both theſe Caſes the drilling is vaſtly preferable to the common Method of ſcattering in the Seeds at Random.

When Saintfoin is drilled for handhoeing, let the Rows be made ſixteen Inches aſunder; and the Plants ſingled out by the Hoer to about eight Inches Diſtance; but let the Hoers take Care to have the ſtouteſt and beſt growing Plants, though they happen in ſome Places to ſtand a little cloſer than the allowed Diſtance, leaving a Space proportioned beyond them.

When it is not intended to be hoed at all, either by the Hoe Plow, or by Hand, the beſt Method is to plant ſingle Rows, at eight Inches Diſtance, with no greater Quantity of Seed than when they are planted at ſixteen Inches. Either Way there will be a profitable Crop: but by what we have ſeen from Experience, the Horſehoeing and the Drill together produce the richeſt, the moſt profitable, and the moſt laſting Increaſe.

CHAP. LXX.

Of the great Advantages of the Drill and Horſehoeing Huſbandry.

WE have now, in a plain and impartial Manner, laid down the Principles upon which the new Method of Huſbandry is founded; the Manner in which it is to be performed; and its Effects on three different Kinds of Crops, the Turnip, Wheat, and Saintfoin. The Farmer muſt, by this Time, very well underſtand its Nature, but it may be proper to cloſe the Account with a ſhort Recital of its Advantages; that what Reaſon ſhews him to be right he may find will anſwer alſo in Practice.

The Farmer, when he comes to count his propoſed Gain, ſhould take into his Conſideration four Things; the Expence of his Crop, the Value of it, the Certainty or Hazard, and the Condition wherein the Land will be left after it.

If the Profit of a Crop were to be computed ſingly from its Price at Market, that of the Drill and Horſehoeing Huſbandry would have the Preference greatly over that raiſed by the common Method: but we are to conſider alſo, that the Expence is greatly leſs; and then we ſhall ſee the Benefit in a new Light.

The Farmer may get more by a very ſmall Crop that coſts little, than by a much larger that he has been at a great Expence to raiſe; but in this Conſideration he has both the Advantages of ſmaller Expence, and greater Value.

All the Articles of Seed, Tillage, Drilling, Weeding, and Reaping, with whatever other leſſer Articles there may be in this Method of Huſbandry, do not amount to above the eighth Part of the Expence in the common Method: therefore, were the Crop much leſs, the Profit would ſtill be very greatly above that of the other: it is plain then how vaſt the Advantage muſt be, when it is as we ſee really greater.

When the Farmer ſhall impartially conſider the different Goodneſs of a Crop, that conſiſting in the Quality, as well as Quantity of the Grain, he will ſee his Advantage in a farther Light; for he will find that Wheat, the richeſt of all Corn, may be raiſed continually upon the ſame Land, and that the Grain will this Way exceed, in every Reſpect, that raiſed by the other Huſbandry. Not only Land will continue to produce Wheat every Year by this Management, but it will grow on Land that would not otherwiſe have yielded it at all, without an Expence of Manure more than equal to the Profit by the Crop; but in this Way of managing Land it will yield exceeding good Crops ſucceſſively, from Year to Year, with no Manure at all; and if a ſmall Expence be added for Manure, the Succeſs by the Aſſiſtance of both will be ſurpriſing.

The Certainty of a Crop by this new Method is much greater than in the old; and this Article of keeping the Farmer's Heart at reſt, during the Growth, is worth ſome Conſideration. In the common Way he often ſuffers by the Ear being too ſmall, by the Want of Quantity, and often from

from its being too large, by the falling. But in the new Husbandry the Ears are never too small, for the Horsehoeing supplies them with Nourishment just for the filling of them, and they are much less liable to lodge, because the Stalks are stronger.

If we lastly examine the Difference between the old or common Method of Husbandry, and this, in the Condition in which the Land is left after the Crop, there is no Comparison, for in the one it is exhausted, and in the other in full Strength. A Field that, after the Expence of dunging, has borne a Crop of Wheat, is not fit to bear another, but the Crop must be changed; and when it has borne two more of an inferior Nature, all the Work must begin over again, for it is exhausted, and will not bear any Crop without refreshing at this great Expence; or else it must be recruited by Fallowing. This is the Condition wherein Land is left after a Crop in the usual Way; but in the Method by Horsehoeing, when it has borne one Crop of Wheat, it is fit for another; and the two Furrows upon which the next Crop is to stand, may be plowed as soon as the other is off. No store Sheep are necessary, for there is no Use of a Fold where the Land has annually a Crop growing on it, and needs no Manure. The Farmer who follows this Method, can plow dry and drill wet, without any Manner of Inconvenience: he can sow early, because he can, in Spring, help the Staleness of the Ground by hoeing: and thus in every other Article he has a certain Advantage.

A poor Ground will produce Crops Year after Year this Way, without Manure or Rest, and they shall be all very good ones; no Decay nor Exhausting, but the Earth all the while improveing.

The Success of Horsehoeing is so evident in the giving Nourishment to the Crops, that there have been some who objected to it, as making the Growth too rank. There could not be a fairer Confession of the Excellence of the Practice: for that which is capable of giving too much Nourishment, may certainly be so managed as to give just enough. It is true, that when Corn is too rank it is liable to many Accidents from that very Cause; but it is in the Power of the Farmer to give it Strength and Vigour enough, without giving it too much; and it is in the most beneficial Things, that the greatest Moderation is necessary.

They say if this Method can enrich poor Land to such a Degree, as to make it bear great Crops of Wheat, it will naturally make rich Land too rank. In this Case the less of it may be used, but we have provided against such Objections already, by advising the Intervals to be smaller in rich, than in poor Ground.

There have been many Objections of the like Kind raised against this Method of Husbandry, but they are such as shew they have risen from prejudiced Persons, and such as were desirous of decrying the Practice rather than of giving it a fair Trial.

As these have been too violent against it, the Advocates in its Favour have been too extravagant in its Praise. Enough may be said in its Cause, without enlarging beyond the Truth, and he who goes farther, hurts the Point he means to serve.

We have, as carefully as we are able, proposed the true State of the Case between the old and the new Method, and of this at least we are sure, we have written with Impartiality. We have stated the Advantages to spirit up the Farmers of our own Country to make a Trial, and would see them influenced by that, rather than by any Arguments; but the Success and Advantage with which it has been used in France makes us earnestly desire it may have fair Play here.

If we were asked whether we think the most Advantage may be had from the common Methods, or from Horsehoeing without Manure, we should answer that doubtless it is from the Horsehoeing Method; but the greatest Advantage possible will be obtained by employing both together!

Having thus laid down at large the Manner of conducting the new Method of Husbandry, and the Advantages arising from it; we shall here add the Thoughts of a practical Correspondent, who has communicated them at large with Respect to the Improvement of Estates, and the Advantages of the new Husbandry; including, under that Name, the Introduction of the several Articles not used by the old Farmers, as well as the new Method of Tillage; and the Management of some particular Grains and Roots.

SIR,

The Improvement of Estates appears so plainly a general Advantage to the Nation, as well as a private Benefit to those who manage it with Discretion, that it would be superfluous to enlarge on a Point which seems in itself so evident.

For whoever encreases the yearly Value of his Estate, so far certainly encreases his own, and the yearly Riches of his Country, according to the Sentiments of a late Author, which may not be improperly applied on this Occasion; "He that makes two Chives of Grass grow where "but one did before, does his Country more "real Good than all the Generation of Politi-"tians together."

To the Profit arising from the Improvement of Lands, we cannot but add, two other very important Articles in Life, viz. Health and Pleasure; both which are the natural Consequence of such Undertakings, and are so great Ingredients in our Happiness, as justly to deserve the Attention of every wise and virtuous Mind.

Some Exercise is generally necessary to preserve the Health of the Body; and some Relaxation and Amusement, are equally beneficial to preserve and improve the Faculties of the Mind.

The Poet justly says,

"The Wise for Health on Exercise depend,
"God never made his Work for Man to mend."

And this, perhaps, is the most justifiable Pretence for our Hare and Fox Hunting, so frequently fatal directly, or in their Consequences, to the Sportsmen, and so generally prejudicial to, and so often attended with the Curses of, their Neighbours.

And might not all the good Ends of ſuch Engagements be eaſily obtained, by viewing thoſe Improvements of an Eſtate, which, if diſcreetly managed, would be far from being expenſive, comparatively with the others; be a Bleſſing to the Neighbourhood by their uſeful Influence, by a virtuous Employment of the honeſt Induſtrious, procuring a laſting Encreaſe of Wealth to a Man's own Family, and perpetual Encreaſe of Riches to our Counrry.

Which Article of improving private Eſtates ſeems more particularly to require the Regard of thoſe Gentlemen, who, being debar'd by our Laws from encreaſing their Eſtates in Land, may be the rather induced and the more inclined to improve the Value of thoſe they are well intituled to; eſpecially as one Pound gained this Way, is generally worth near two of old Rents, as it is ſcarce ever loaded with additional Taxes or Aſſeſſment.

And how fine and pleaſing a Proſpect muſt it be, to ſee an Eſtate well laid out, and in good Order, well fenced, and tenanted, and the yearly Value thereof greatly encreaſed, as well as the Good of the Tenants promoted, with much leſs Expence than a Pack of Dogs, a Brace of running Horſes, a ſhowy Houſe, or a pompous Piece of Water, would occaſion; but Cuſtom and Faſhion ſeem herein too much to prevail with Gentlemen, againſt plain Reaſon and good Senſe.

I ſhall only mention, after Cowley, one Delight more, the moſt natural and beſt natured of all others, a perpetual Companion of the Huſbandman; and that is, the Satisfaction of looking round about him, and ſeeing nothing but the Effects and Improvements of his own Art and Diligence; to be always gathering of ſome Fruits of it, and at the ſame Time to behold others ripening, and others budding; to ſee all his Fields and Gardens covered with the beauteous Creatures of his own Induſtry; and to ſee, like God, that all his Works are Good.

Indeed I cannot be ſo ſanguine as to think with that ingenious Writer, that if Perſons of tolerable Circumſtances ſerved Apprenticeſhips to this Art, "That we ſhould ſee as many Aldermen's Eſtates "made in the Country, as now we do out of "all Kind of Merchandizing in the City," yet I verily believe, that if our Gentry would turn their Thoughts to Subjects of this Nature, inſtead of ſome other Purſuits in vogue, it would ſave many a fine Eſtate, and preſerve many an antient Family from Ruin; and as to the plain Lucre of it, I have known ſome Inſtances where Perſons in very private Stations have gained ſome Hundreds a Year, by taking long Leaſes of uncultivated Lands, and only fenced and limed them well, and then ſet them out again; whilſt others have paid the Purchaſe Money of good Eſtates, by the improved Produce of the Lands; and I have known an Eſtate ſold at five and twenty Years Purchaſe, parcelled out in Farms at five and thirty, and ſome of thoſe ſold again at five and fifty, and they then brought in near five Pounds per Cent. and the Tenants then did as well as at firſt. Such an Improvement was made of the Value of the Farms, by only taking the Field Land into Cloſes by good Walls, and then improving them by Lime, or by Lime and Soil, or Dung in proper Compoſitions.

As to the Uſefulneſs of Engagements of this Kind to the Mind, as well as to the Health of our Bodies, I believe that I may venture to affirm, that I ſhall herein meet with the concurring Opinions of our beſt Phyſicians, as well as the general Practice of the moſt conſiderable Perſons of all Stations, who take all Opportunities of getting into the Country whenever their Affairs will permit, of which any Perſon near the Metropolis may be a daily, or at leaſt a weekly Spectator.

And whoever ſeriouſly conſiders that our Souls and Bodies are ſtrangely cloſely united, and wonderfully reciprocally affect each other, the Truth of which every Man's Experience muſt ſurely convince him of; though it exceeds the Wiſdom of the greateſt Philoſophers, to explain the Manner how an immaterial Soul, and a material Body can operate on, and influence each other after that ſurprizing Manner, conſtant Experience convinces us they do, and how neceſſary it is to preſerve a proper Tone, State, or Harmony of each, in order to preſerve the regular Operations of both. This will evidently ſhew the abſolute Neceſſity there is, from our very Nature, to have ſome Relaxation from, or Change of Employment, to preſerve that Health of Body, and thoſe Faculties of our Mind, which may enable us to preſerve both ſound enough to perform the neceſſary Duties of Life in our ſeveral Stations, and conſtitute what we call, a ſound Mind in a ſound Body; which whoever poſſeſſes, in Mr. Locke's Opinion, wants little elſe neceſſary to the Happineſs of this Life.

The Innocency of this Life, ſays Cowley, is the next Thing for which I commend it, and if Huſbandmen preſerve not that they are much to blame, for no Men are ſo free from the Temptations to Iniquity. And ſpeaking of Children being taught early to Dance, &c. he adds, But did ever any Father provide a Tutor for his Son, to inſtruct him betimes in the Nature and Improvements of that Land he intended to leave him?

I would not here be thought to engage Gentlemen in Huſbandry, as a conſtant Occupation, or to expect they ſhould hold the Plow, or fill the Dung Cart.

But can they, whoſe Health or Affairs require their Reſidence in the Country, employ their ſpare Hours in more uſeful, more innocent, or more delightful Engagements?

The Mind of Man muſt be employed, or will grow ſtrangely out of Order, and theſe Methods of doing it may probably be of much greater Service to the young and unexperienced, than ſome in Years are willing to allow; at leaſt they may amuſe, and innocently engage ſome who want proper Subjects to employ them: and probably may ſerve to open their Minds, and give them ſuch a Train of Thinking, which may lay a Foundation for, or promote ſuch a Method of Application to Buſineſs, as may end in a ſolid Judgment; and if purſued with Diſcretion directly, or in its Conſequences, may diſpel the Tediouſneſs of many a melancholy Hour, remove the Anguiſh of many a ſorrowing Heart, procure

the Eaſe of many an unhappy Family; and lay the Foundation of eſtabliſhing or continuing a Steadineſs of Virtue in many an innocent, thoughtleſs, unguarded Heart.

If then Health, Pleaſure, and Profit are the natural Conſequence of Undertakings of this Nature; it may not be improper here to inquire, how they come to be ſo little purſued; and what Lion there is in the Way to obſtruct or terrify us from endeavouring, by ſo eaſy an Application, to procure Health, Eaſe, Plenty, and Peace.

Now to what is before-mentioned, three Things may probably be objected.

That it is beneath the Dignity of a Gentleman, to engage in Affairs of this Nature.

That ſeveral who have buſied themſelves in Buildings, Alterations, and pretended Improvements, have felt fatal Effects from ſuch Undertakings. And

Laſtly, That Gentlemen are generally unacquainted with Affairs of this Nature; and conſequently liable to be frequently impoſed on in the Management, and deceived in the expected Succeſs of ſuch Projects.

To the firſt of theſe it may be anſwered, That we do not propoſe that Gentlemen ſhould condeſcend to the meaner Labours of the Huſbandman; but ſure a prudent ordering of a Gentleman's own Affairs, can never be thought below the Dignity of a wiſe Man; and if the Arguments and Examples of the greateſt Men in moſt Ages, might prevail againſt the weak Modes and Practice of the Moderns; that Method of Life can never be contemned, on which TULLY, VIRGIL, and HORACE, have beſtowed ſuch large Encomiums; from which Dictators have been called to the Command of Armies, and to the Pleaſures of which mighty Emperors have retired from the Fatigues of Grandeur. A Life choſe by SCIPIO, as mentioned by SENECA.

In this Corner that great Man (SCIPIO) "the "Terror of CARTHAGE, and to whom ROME "owes that it was but once taken, after ma- "nuring his Fields with his own Hands, would "waſh himſelf," for he choſe to work, and tilled his Ground himſelf, according to the Cuſtom of our Anceſtors.

As to the ſecond Thing objected; the ill Conſequences Applications of this Kind may be thought ſometimes to have produced; I believe, if thoſe Inſtances were particularly enquired into, the Ill would commonly be found to ariſe from ill-deſigned, ill-executed, or extravagant Houſes, Out-houſes, Dog Kennels, or monſtrous Gardens; an Inſtance of which I ſaw in YORKSHIRE, where a Gentleman was drawn in to ſpend near ten Thouſand Pounds, without finiſhing any one wiſe and uſeful Thing; and was ſtill purſuing the ſame Methods, to his Ruin, had he not been ſtopt by the friendly Advice of one, who thereby made both him, and his former Adviſers, his inveterate Enemies: and I preſume, ſimilar Inſtances of Folly may alſo be found in moſt Parts of the Nation; but we cannot thence juſtly conclude againſt prudent Buildings, and uſeful Improvements; eſpecially if proper Care be taken to act cautiouſly in new Experiments, and to have Trials made, and repeated in ſmall Parcels, before large Expences are hazarded in great Undertakings.

As to the laſt Objection, That Gentlemen are often unacquainted with Affairs of this Nature, and for that Reaſon liable to be greatly impoſed on, and conſequently to ſuffer both in their Characters and their Fortunes: the Truth of this is not to be denied, without departing from that Sincerity we profeſs to adhere to, but at the ſame Time we declare it to be the principal Intent of this our preſent Undertakings, to provide a proper Remedy for this Inconvenience, by laying down Rules to guard the Unwary, to guide the Unexperienced, and to be of ſome Uſe and Service to all.

Improvements of Eſtates may be conſidered in three Views, as they ariſe from what I chuſe to call natural Improvements; ſuch as convenient Buildings, laying Lands commodiouſly together, dividing them into proper Parts, fencing them well, with Things of the like Nature; without any way meddling with the Surface or Soil, by either common or artificial Manures or Management.

Secondly, By what may be called artificial Improvements, as by Lime, Salt, or Burnbaiting, called Denſhiring; and all the different Sorts of Foreign Graſſes, ſuch as Clover, Saintfoin, and many other Things of the like Nature; ſeveral of which have been treated of before particularly, and the reſt will be hereafter.

Laſtly, As they ariſe from the common or late improved Methods of Huſbandry, ſuch as dunging, plowing, and prudent managing of all Sorts of Ground, according to the preſent beſt Methods eſtabliſhed by the moſt obſerving Gentlemen, and the moſt experienced Farmers, in different Counties, and on Lands of different Natures.
